With a splendid exhibit of twelve large-flowered varieties, such as Betty Snow, Jenny and Sunset, Messrs. G. Mair and Sons won the first prize. In the floral classes, Mrs. Yandell was first (a) with a handsome bowl of large-flowered varieties; (b) a vase of large-flowered; (c) a vase of Primulinus varieties; (d) three bowls of Primulinus varieties, and (e) an artistic dinner table decoration of Primulinus Gladioli.

Amateurs' Classes.

In the principal section for amateurs, the competition in the larger classes was disappointing, although the exhibits were of good quality. Mr. W. E. Samuel, Wrexham, was awarded the first prize for twenty-four British varieties of either section, where he showed some good seedlings and Mandarins; in Class 19, for a similar number, his first prize exhibit included Priscilla, Allen, Butter Boy, Catherine Colman and Marie Lion; while among his exhibit of American varieties were good spikes of Ethelyn, Salmon Beauty and Gryon Meadel. Mr. D. Whitelaw, Laurencekirk, won the *Homes and Gardens* Trophy with an interesting collection. First prizes were awarded to Mr. A. E. Amos, Colchester, in Class 22; to Major Churcher, Lindfield, in Class 23; to Mr. G. Williams, Preston, in Class 25; and to Mr. W. E. Phillips, London, in Class 26, for praiseworthy exhibits, although, unfortunately, they had no competitors. Mr. D. Whitelaw won first prizes for three distinct spikes of large-flowered varieties and for three spikes of one variety. Mr. W. E. Samuel had the best three spikes of distinct Primulinus grandiflorus varieties, and Mr. G. Williams, Preston, had the best three of Primulinus.

The colour classes, which required one spike, were well contested. Mr. Whitelaw won first prizes for the following large-flowered varieties: cream and white; Pfitzer's Triumph, crimson; Sunset, orange or yellow; Irene, pink, rose or salmon; Guy Mannering, violet or purple; and Rosella Amos, any other colour. With Marmora, Mr. W. E. Samuel was first for lavender, lilac or mauve. In the similar classes for Primulinus varieties, Mr. J. Howarth, Tottington, was first, with Ethelyn, yellow, and Pfitzer's Triumph. Mr. W. E. Samuel showed, in a good seedling, the best white. Mr. P. S. Todd won with Lilac Queen, and Mr. H. E. Tyrer, Penwortham, showing Jewel, was first for pink, rose or salmon; Taurus, shown by Mr. G. Williams, was the best in the any other colour class.

The quality was particularly good in Group C., where Mr. Whitelaw, showing King George, Queen Mary, Mrs. T. Malthouse and Apricot, of considerable excellence, was first in the class for six large-flowered varieties. Mr. T. Jones was second with three unnamed sorts. Mr. Whitelaw again was first in the class for six Primulinus, where he included Salmon Beauty, Sunset and Nydia, of graceful beauty. In the Southport area class, Mr. R. Ackers had six excellent spikes.

The non-competitive exhibits filled considerable space and were a very attractive feature of the show. Messrs. W. J. Unwin, Ltd., had a very large group of representative sorts, as also did Messrs. Kelway and Sons. Messrs. R. H. Bath, Ltd., and Messrs. Bees, Ltd., set up very imposing displays, while Messrs. W. Artindale and Son, had a well arranged collection, mostly of the large-flowered varieties. Mr. H. Prins had many baskets of Gladioli, and Messrs. Rowlands and Co. showed large-flowered sorts in variety.

Obituary.

Alwin Neumann.—We have to record the death, on August 9, of a well-known German nurseryman, Alwin Neumann, of Unwürde-Lõbau. Deceased was born in 1865, and was the son of a nurseryman. After varied experience, he founded his own nursery in 1902, which, from a small beginning, attained to a remarkable development. He specialised in Roses and ornamental trees, and latterly 100,000 Roses alone were sent out of the nursery every year. The business will be continued on the same lines as before by his son, but German horticulture is the poorer by Neumann's death, and his many friends will long mourn his loss.

ANSWERS TO CORRESPONDENTS.

Aphis on Peaches under Glass.—*J. J.* Your trees are attacked by Aphis pruni, which attacks Plums and Peaches, and if neglected causes considerable trouble before the trees can be cleansed. If taken in time it is easily destroyed by fumigation or Quassia extract, or, better still, should be prevented by spraying the trees before and after they have flowered with Quassia extract; two or three times during the growing season will be sufficient. You can use at this season as a liquid manure, one ounce of sulphate of potash, or half-an-ounce of phosphate of potash per gallon of water. If it is desired to apply potash, this should be applied in early winter, when the roots are at rest, and provided the necessary lime is present sufficient potash will remain in the soil for the roots in the following spring and summer.

Apple and Pear Leaves Scorched.—*G. F. P.* The Apple foliage shows signs of leaf-scorch. The Pear foliage shows similar damage, and this may be due to inadequate drainage. The roots may have either penetrated into an unsuitable medium, or they are lying on top of a "pan" so that they become saturated with water. Pay attention to the drainage and ascertain the position of the roots by digging a trench around the trees about four feet away from the main stem, in late autumn.

Copper Beech Trunk Rugged at Base.—*H. L.* As you suggest, the roughened portion at the base of your Copper Beech tree is probably the junction of the stock and scion.

Chrysanthemum Foliage Curling.—*G. E. W.* The cause of the Chrysanthemum foliage curling is due to a mite, Tarsonemus species. The damage has been going on for some time and mites are still to be seen on the leaves. The remedy is to use either a sulphur-soap dip, or to spray both surfaces of the foliage with Volck, which allows the new growth to grow away clean and free from infection.

Horse Chestnut Tree Diseased.—*W. C.* The Horse Chestnut tree, of which a specimen was sent, has apparently died from fungus injury. It is quite likely that the trouble occurred through root injury either by the roots becoming too wet, or the ground may have, at some time, become very dry; either condition would probably have the same effect. It is impossible, without examining the tree and the conditions under which it is growing, to state what has actually caused its death, but everything points to root trouble. So many as possible of the roots should be dug out and if a young tree is planted new soil should be introduced.

Lawn Sand.—*H. J. H.* Lawn sand is made in a variety of ways, and with different materials or mixtures, but usually consists of sulphate of ammonia, in a dry and very finely powered state, and very fine sand, also dry; coarse materials are liable to roll off the leaves of weeds and be lost. Some gardeners use sulphate of ammonia and sand in equal parts, which is a strong mixture if put on thickly by any distributing machine, like a broadcast corn-sower, which, however, has a contrivance for regulating the amount distributed. If you desired to weaken the mixture you could use one part of sulphate of ammonia to two parts of sand. A modification is to use one part of sulphate of ammonia, half a part of common or table salt, and two parts of sand. The first two have a more powerful effect upon the weeds, while they do not have the same effect upon the roots of the grasses, because they do not utilise common salt, and could only take up a certain amount. The day should be fine, and the grass dry when either of the above lawn sands are applied. They begin to act within an hour of application. Fine sand can be found in your own immediate neighbourhood.

Lupins Dying.—*H. V.* The Lupin plants show signs of infection from the root-decaying fungus, Thielavia basicola. Plants growing in poorly-drained soils are more liable to attack than those growing in well-drained soil. Apply a dressing of sulphate of potash (one ounce to the square yard) in autumn and early spring around the infected plants.

Names of Plants.—*E. M. B.* Cannabis sativa.—*C. C. T.* Cercidiphyllum japonicum.—*C. H. C.* Euphorbia marginata.—*Mona* 1, Nandina domestica; 2, Bougainvillea glabra var. Sanderiana variegata; 3, Rhoeo discolor; 4, Panex fruticosum var. Guilfoylei; 5, Sanchezia nobilis; 6, Isoloma hirsutum; 7, Aglaonema Haenkii; 8, Heliconia psittacorum; 9, Alocasia macrorhiza var. variegata; 10, Strobilanthes Dyerianus; 11, Pellionia Daveauana; 12, Acalypha marginata; 13, A. Hamiltoniana; 14, Nephthytis liberica (green), and N. picturata (variegated).—*A. H. S.* 1, Sedum rupestre; 2, S. spurium var. album; 3, S. reflexum; 4, S. spurium. *A. Z.* 1, Anthemis tinctoria; 2, Scolopendrium vulgare, a depauperate form; 3, Cyrtomium falcatum; 4, Erigeron speciosus.—*H. B.* Rose Veitchenblau.—*H. E. J.* 1, Ailanthus glandulosus; 2, Qiercus coccinea; 3, Q. palustris; 4, Picea orientalis; 5, Pinus Strobus; 6, Cupressus Lawsoniana var. albo-spica; 7, Sequoia sempervirens; 8, Thuya dolabrata; 9, Cupressus sempervirens; 10, Juniperus virginiana; and 11, Cedrus Deodara.

Peach Leaves Mildewed.—*A. S. G.* The Peach leaves are suffering from a severe attack of mildew, and some red spider is present on the lower surface. The general appearance of the foliage suggests that some cultural defect, such as faulty watering, is also responsible for the trouble. Constant care has to be taken in the cultivation of these trees and more attention must be paid to the state of the border in which they are growing. Dust the infected foliage when it is moist after syringing with green sulphur.

Tomato Foliage Diseased.—*C. A. W.* The Tomato foliage is suffering from an attack of leaf-mould, due to the fungus Cladosporium fulvum. The most satisfactory control method is the provision of a dry atmosphere and efficient ventilation in the house. Trim off excess foliage to allow free circulation of air around the plants. Dusting the plants with green sulphur when the foliage is moist will act as a preventive to the spread of the disease.

Walnut Tree Failing to Fruit.—*R. W.* It is quite probable that your Walnut tree will produce fruits again next year. There is no need to supply any special dressing to the soil. Its failure during the present season to produce fruits may be due to some local peculiarity, or the frosts of the last two seasons may have weakened the tree to some extent. There does not appear to be any cause for alarm as to the health of the tree or its future fruiting.

Virus Diseases of the Potato.

THE most recent researches* into Potato virus diseases, made by Dr. Kenneth M. Smith, at the Potato Virus Research Station, Cambridge, add considerably to the knowledge of the nature and behaviour of these extraordinary maladies. The virus disease which has been investigated by Dr. Smith is Mosaic. It has long been suspected that the agents which disseminate Mosaic are Aphides, and now Dr. Smith has succeeded in demonstrating beyond cavil that the Aphis, Myzus persicae, is the culprit, and that perhaps this Aphis has an accomplice in another Aphis, Macrosiphum gei, in the work of distributing Mosaic from Potato to Potato plant. Although, if we may judge from the prevalence of Potato Mosaic, infection in nature must be easy enough, it would appear to be by no means so easy to induce Mosaic under artificial conditions. Nevertheless, the evidence obtained by Dr. Smith appears to be conclusive that Aphides are the agents which disseminate the disease. Attempts to discover other carriers among the insect visitors of the Potato have so far proved unsuccessful in all cases with the possible exception (already mentioned) of the Aphis, Macrosiphum gei. Attempts to ascertain how the Aphis inoculates the Potato plant have so far proved unsuccessful. Extracts of the body juice of the salivary glands of M. persicae which had lived freely on Potatos infected with Mosaic failed, when injected into healthy Potatos, to bring about infection. Yet, curiously enough, it is easy to cause Aphides of the infective species to bring about disease in Tobacco plants. Although the disease induced in the latter is not identical with Mosaic, so far as symptoms are concerned, there can be no doubt but that it is brought about by the virus which causes Mosaic in Potatos. Moreover, the scratch of a needle may be used to transfer virus from a Potato affected by Mosaic to a susceptible variety of Tobacco, and as a result of the inoculation a disease named Ring Spot is induced, the symptoms of which are similar, although not identical, with those which occur when the Aphis inoculates Tobacco plants with the Mosaic virus. That Mosaic of Potatos is due to the same virus as Ring Spot of Tobacco is proved by the fact that when healthy Potatos are inoculated with the juice of Tobacco plants infected with Ring Spot they develop Mosaic disease in a more virulent form than that which characterised the Potato from which the virus was originally taken. Evidently, therefore, evil communications corrupt not only good, but also bad manners. Once this intensified virus is planted in the Potato it may be spread with ease from Potato to Potato by the simple means of a needle scratch, but, curiously enough, the Aphis, Myzus persicae, does not appear capable of transferring the intensified virus from one Potato plant to another. Finally, and not the least interesting of these researches, it has been shown by Dr. Smith that the virus of Potato diseases and of Tobacco Ring Spot is a filter passer. Juice of a Potato plant infected with the intensified Mosaic and from a Tobacco plant infected with the Ring Spot, may be filtered through Pasteur Chamberland filters—which arrest ordinary micro-organisms—and still retain the power of setting up these diseases in Potato and Tobacco plants, respectively. It is some relief to learn that the virus of Tobacco Ring Spot, which, as already explained, is derived from that of Potato Mosaic, is not able to set up disease in every kind of plant. Inoculated in Tomatos it only mottles the leaves. In Petunias it causes mottling, with some distortion, but with Solanum nigrum, Spinach and Cabbage it produces no symptoms. Clearly we are at the beginning of a new and vastly important epoch in the history of discovery of the nature of plant diseases, and, as is usual with beginnings, things look very puzzling and difficult. Nevertheless, at the rate at which knowledge is progressing, it will probably not be long before some of these strange mysteries of Mosaic and other virus diseases are resolved, and who knows, perhaps with this knowledge may come means of getting rid of them!

John Cypher Memorial.—The following contributions, or promises, have been received for the fund that is being raised to provide a memorial to the late Mr. John Cypher, V.M.H.:—Southport Flower Show Committee, £25; Alderman C. Aveling, Southport, £5; Mr. R. F. Felton, Hanover Square £25; Mr. W. B. Cranfield, Enfield, £2 2s.; *The Gardeners' Chronicle*, Ltd., £5 5s.; Mr. Charles H. Curtis, £2 2s.; Mr. C. H. Taudevin, Willaston, Birkenhead, £1 1s.; Mr. F. Jordan, Lingfield, £1 1s.; Mr. T. Hay, Hyde Park, £2 2s.; Mr. H. Hicks, Manchester, £1 1s.; Messrs. Dickson and Robinson, Manchester, £2 2s.; Mr. G. M. Taylor, Portobello, £2 2s.; Mr. H. G. Alexander, Tetbury, £1 1s.; Rev. A. C. Hall, Southport, £1 1s.; Mr. C. H. Cook, Windsor, £1 1s.; Mr. T. J. Nelson, Ashby Lodge Gardens, Chesterfield, 10s.; Mr. R. L. Harrow, Edinburgh, £1 1s.; Mr. Cyril Lockwood, Sheffield, £1 1s.; Mr. James Gutteridge, Sefton Park, Liverpool, £1 1s.; Mr. J. Brook, Mayor of Southport, £5 5s.; Mr. J. H. Wood, Fitzroy Street, W., £2 2s.; Mr. R. Findlay, Wisley, £1 1s.; Mr. D. Campbell, Regents Park, £1 1s.; Mr. A. J. Macself, *Amateur Gardening*, Aldersgate Street, E.C., £1 1s.; Mr. T. Pateman, Brocket Hall Gardens, 10s. 6d.; Mr. Peter Blair, Trentham, 10s. 6d.; Mr. A. E. Perkins, Coventry, £1 1s.; Mr. T. H. Cook, Sandringham, £1 1s.; Mr. David Cuthbertson, Edinburgh, £2 2s.; Dr. F. W. Stansfield, Reading, £2 2s.; Mr. R. Manning, Dudley, £2 2s.; Mr. A. H. Holmes, Chesterfield, 10s. 6d.; Mr. W. H. Stansfield, Southport, £1 1s.; Mr. Allan Falconer, Cheadle, £1 1s.; Mr. C. Cooper, of Messrs. J. Peed and Son, £1 1s.; Mr. A. Mason, Newby Hall Gardens, Ripon, 4s.; Mr. J. Walker, Finney Lane, Cheadle, 5s.; Mr. N. F. Barnes, Eaton Hall Gardens, £2 2s.; Mr. T. A. Longworth, Park Villas, Manchester, £5 5s.; Mr. J. S. Brunton, Burnley, £5 5s.; Mr. R. Greenfield, Leamington Spa, £1; Mr. W. H. Kitching, Warter Priory Gardens, York, 5s.; Mr. J. Hathaway, Baldersby Park Gardens, Ripon, 5s.; and Mr. J. Benstead, St. Nicholas Gardens, Richmond, Yorkshire, £1. Contributions should be sent to the Hon. Secretary and Treasurer, Mr. Charles H. Curtis, 5, Tavistock Street, Covent Garden, London, W.C.2.

Legacies to Gardeners.—Mrs. Albinia Mary Lyon, of The Grove, Teignmouth, who died on May 3, left £50 to her gardener, Mr. William Milliam, if still in her service.—Mr. Thomas Ritchie, of Watercroft, Penn, Buckinghamshire, left £10 for each year of service to his gardener, Mr. Henry Wadley.—The Earl of Durham, of Fenton House, near Wooler, Northumberland, who died on January 31, 1929, left £100 each to his gardeners, Mr. Alec Scott and Mr. W. Pattie.—Colonel C. W. H. Lowther, of Hurstmonceux Castle, Sussex, left £250 to his gardener, Mr. William Parker, and £50 each to Messrs. Dann, Billingness and Hall, under-gardeners.—Mr. Orsini Stuart, of Elm House, Seaforth, left £65 to his gardener, Mr. William Hurst.

German Park Superintendent's Long Service.—Herr Ludwig Simon, Parks Superintendent of the German town of Gelsenkirchen-Buer, completed on July 15 his thirtieth year in the service of the municipality. He was born in 1870 in the Province of Saxony. In 1899, after a period spent in obtaining varied experience in gardening, he was entrusted with the care of the South Park in Ueckendorf, which was later included in the municipality of Gelsenkirchen, of which town he later became Superintendent of Parks and Open Spaces. He has exceptionally wide knowledge and experience in all matters pertaining to his work, and the excellent appearance of all the numerous open spaces under his care testifies amply to his unremitting attention and devotion to his task.

A New Michelia.—In the Kew *Bulletin of Miscellaneous Information*, No. 7, 1929, Mr. J. E. Dandy records a new Michelia from the borders of Tibet and Assam. It was collected by Captain F. Kingdon Ward in the region of the Mishmi Hills, during 1928, and has been named Michelia Wardii. In this *Bulletin* Mr. W. B. Turrill continues his notes on the flora of the Nearer East; Mr. Karel Domin contributes "New Ferns from Tropical America and the West Indies," and Mr. T. A. Sprague informs us that under International Rules and American Code, the correct name of Shrub Yellow-root is Xanthorhiza simplicissima, Marsh, not Zanthorhiza apiifolia, L'Hérit.

Certification of Black Currant Bushes in Scotland.—The Department of Agriculture for Scotland announces that the inspections, in connection with its scheme inaugurated this year, for the certification of Black Currant bushes grown in Scotland and intended for sale. have now been completed. Certification of bushes has followed, so far as possible, the following group classification adopted by the East Malling Research Station:—1, French; 2, Boskoop Giant; 3, Victoria or Goliath; and 4, Baldwin. The Certificates issued as a result of the inspections relate solely to the purity of the stocks and their apparent freedom from Reversion, and are not to be regarded as guarantees of complete freedom from disease. Care has been taken, however, not to certify stocks which were found to be obviously unhealthy or lacking in vigour. Certificates are valid only up to April 30, 1930, and growers to whom they have been issued have given undertakings that they will be used only in connection with the bushes actually inspected and certified by inspectors of the department. A list of the stocks certified this season, together with the names and addresses of the growers, may be obtained upon application to the Ministry.

---

* "Studies in Potato Virus Diseases, No. IV. Further Experiments with Potato Mosaic," by Dr. Kenneth M. Smith; *The Annals of Applied Biology*, XVI, Feb. 1, 1929.

Belgian Market Salesmen's Reunion.—On Sunday, August 25, the Brussels Market Salesmen's Club celebrated the twenty-fifth anniversary of its foundation, in the Gothic room of the Town Hall. The members went in procession to the Hall, where they were received by the Burgomaster, M. Adolphe Max. M. Fernand De Clercq, the President of the Club, introduced the members to M. Max. M. Louis Bracke, President of another more recently-formed Market Club (l'Amicale) also spoke, and M. Max replied. The reception over, the members passed on to the headquarters of the "Amicale" Club, where a handsome medal was presented to M. René Borremans, the chief commissary of the Town Markets. The Company then went on to the headquarters of the Market Salesmen's Club, where the rooms were gaily decorated with flowers for the occasion, and thus ended a ceremony very typically "Bruxellois."

Trials of Novelty Sweet Peas.—Mr. J. Stevenson has kindly offered to grow the National Sweet Pea Society's 1930 trials of novelty Sweet Peas at his New Milton grounds, Dorset. The Committee has decided to shade salmon and orange-coloured varieties, when desired, at an additional charge of 2s. 6d. per variety, to pay the cost of shading. The fee for unshaded varieties is 7s. 6d. per set. Not fewer than thirty-six seeds of each variety are required for trial. Raisers who wish their novelties to be included are asked to notify the Secretary, 19, Bedford Chambers, London, W.C.2., who will send the required number of seed pockets.

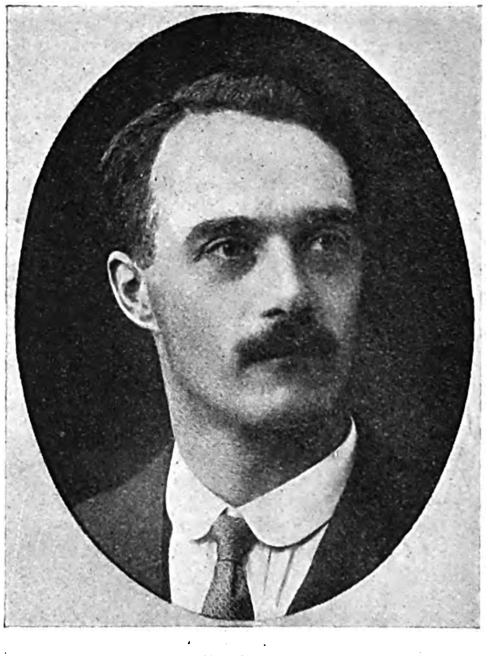
Rice Grass.—The Ministry of Agriculture has recently issued a pamphlet on Rice Grass and its economic possibilities (Miscellaneous Publication No. 6, price 8d. post free). It will be of particular interest to those concerned in protecting land from inundation from the sea, as Rice Grass is a very powerful means of consolidating marshy land and maritime muds. Its root systems become very extensive and deep-seated, and its grass is of a type suitable for fodder for farm stock. Successful work with this grass has been carried out in Holland and certain parts of the coast of this country, particularly in the south of Hampshire, Poole Harbour, and in Essex.

Essen Horticultural Exhibition.—The International Horticultural Exhibition now being held in Essen, Ruhrland, Germany, is attracting immense throngs of visitors. Up to August 19 (on which day there were about 50,000 present) 800,000 people had visited the show, comprising a great number of different nationalities.

Sweet Pea Show in Brussels in 1930.—The Sweet Pea Exhibition in Brussels is not long over, but the indefatigable officials of the Society, known as "Les Amis des Pois de Senteur," are already planning next year's show, which, in view of the importance of the celebrations taking place in 1930 for the centenary of Belgian independence, is to be of an international nature. It will take place in Brussels, on June 28, 29 and 30, and enquiries for space have already been received from a number of firms, including some from half-a-dozen different foreign countries. Valuable prizes are to be offered for competition, and a large concourse of visitors is almost certain.

International Peace Garden in America.—If the proposal advanced at the recent annual convention of the International Association of Gardeners, and referred to at length in our issue of August 31, p. 168, is accepted, a four-hundred-acre International Peace Garden at some point on the boundary between Canada and the United States will be established. The delegates at the Convention considered the best memorial to mark the peaceful relations which have existed between the two countries for more than a century would be a spacious flower garden. The exact location of the garden is to be discussed at a future meeting. It is proposed that two hundred acres shall be in the United States territory and two hundred acres in Canadian. A suggestion to raise a fund of $5,000,000 for the project was advanced, the money to be raised by inviting adults in Canada and the United States to contribute 25 cents. each and children 5 cents. Leading men of both countries have expressed their approval of the proposal.

Mr. Alex. S. Hay.—After attending the County Grammar School, Market Harborough, for three years, Mr. Alex. S. Hay commenced his gardening career under his father at Hothorpe Hall, Leicestershire, the residence of C. E. de Trafford, Esq. At Hothorpe Hall he passed through the various departments and received a good all-round training. In 1915 he joined His Majesty's forces and saw considerable service in France. On the cessation of hostilities, Mr. Hay returned to Hothorpe Hall, and took charge of the glasshouses for a short time before passing on to Welbeck Gardens, Worksop, under Mr. James Gibson. There he remained five years, during the last four of which he held the position of general foreman. From Welbeck, Mr. Hay went to Stagshaw House, Corbridge, the residence of J. C. Straker, Esq., to take charge of the gardens there, and he has now occupied this position for five years. During these five years most of the glasshouses have been rebuilt and the fruit trees replaced. The Rose garden has been altered, and alterations on the front of the house and in the rock gardens are being carried out. Mr. Hay is Chairman of the Corbridge Chrysanthemum Society, and is a well-known exhibitor. Last season was his most successful one as an exhibitor, his final success being the winning of the W. F. Henderson Silver Cup for Chrysanthemums at Newcastle.



MR. ALEX. S. HAY.

Cactus Exhibition in Frankfurt.—From August 3 to 26, an exhibition of Cacti was held in the greenhouses of the Palm Garden in Frankfurt a/Main, Germany, which was visited by many people and proved a great attraction. Cactus culture is already very popular among amateurs in Germany, and the taste for it appears to be growing steadily.

Presentation to Mr. J. B. Jack.—A deputation of the Hamilton and District Gardening and Forestry Association met recently at Redholme, Woodside Walk, Hamilton, to do honour to one of the Vice-Presidents, Mr. J. B. Jack, of Motherwell Parks Department, on the occasion of his leaving for America. Mr. Gibson, President, invited Mr. Graham to make the presentation, which he did in a few well-chosen words, and handed Mr. Jack a gold watch, beautifully inscribed, as a recognition of the work he had done among the members of the Association. Mr. Jack thanked all who had subscribed to the gift, and hoped that the Association would continue to flourish. The members very much regret the loss of a capable gardener and adviser. Mr. Jack has filled important positions in some of the best establishments in Scotland, and during his stay at Motherwell has shown great taste in the design of his floral displays. He also excelled in the cultivation of Chrysanthemums, his annual displays of these never failing to draw large crowds to the park. Mr. Jack was held in high esteem by all members oft he Parks Department, who presented him with a Masonic emblem in gold.

Bee Exhibition in Berlin.—Early in August 9 to 12, an international meeting of Bee enthusiasts was held in Berlin, under the auspices of the Apis Club. There were visitors from almost every civilised nation, and a varied programme of discussions, demonstrations, etc., found ready acceptance. The visitors were delighted with the very complete section dealing with bees and apiculture in the Berlin Museum, and also with a steamer trip to the Bee farm of the apicultural institute.

Liege Exhibition, 1930.—During the spring and summer of 1930 (the centenary year of Belgian independence) an international agricultural and horticultural exhibition will be held at Liege, which is recognised by the Government, and is likely to be of considerable importance. A piece of parkland, about fifteen hectares in extent, on the banks of the beautiful River Meuse, has been set aside for the exhibition, and besides a permanent exhibition, there will be temporary shows of various plants and flowers according to the passing seasons. English and other horticulturists desiring space should apply to the exhibition authorities, at 4, Place St. Lambert, Liege, Belgium.

Suggested Improvements in the Royal Parks, London.—A statement issued by the Office of Works is to the effect that the First Commissioner of Works, Mr. Lansbury, has received several promises of assistance from generous persons towards the cost of providing shelters and other amenities, particularly in the interests of the children, in the Royal parks. Among others, offers of £500 each have been received from Sir Arthur du Cros and Mrs. Van den Bergh. A donor, who wishes to remain anonymous, interviewed the First Commissioner of Works, and in additon to promising a sum of £500, undertook to give a sum of money up to £5,000, provided the Government would agree to contribute an equal sum, for the purpose of providing facilities for children and also to render it possible for both sexes to bathe in the Serpentine and for sun-bathing. Mr. Lansbury gladly accepted the offer, subject to the approval of Parliament.

Allotments in Distressed Mining Areas.—Among the questions considered by the Central Joint Committee of the Lord Mayor's Fund for the Relief of Distressed Mining Areas in England and Wales, was that of allotments. The Interim Report of the Committee, published in July, states that the Committee were unable to deal with the matter until very late in the season this year; but the principle of giving assistance towards the proper cultivation of allotments by unemployed persons in distressed mining areas was strongly approved, and Divisional Committees were instructed to co-operate with the various County Agricultural Committees in their areas and with the Society of Friends, who had already been at work on allotment schemes in many areas, in order to render the maximum amount of assistance. Full details of the work carried out were not available at the time this Report was prepared, but it was clear that a very large number of allotments have been kept under cultivation that would otherwise have become derelict. Assistance has been given to between 60,000 and 70,000 allotment holders, mainly in South Wales, Durham and Yorkshire, the total cost of the service being approximately £15,000. The assistance has taken the form of the provision, after investigation, at a reduced or nominal rate, of seeds, seed Potatos, fertilisers and, where necessary, fencing material. In some cases, arrangements were made to spread the small payments required from recipients over the summer months. The Committee hopes to provide for this work to be carried out more extensively and thoroughly next season, when more time will be available to make the necessary preliminary arrangements. In the meantime, it is satisfied not only that the expenditure incurred has provided a quantity of food where it was badly needed, but that the work involved in the cultivation of allotments has provided some occupation and incentive for a number of men, and has been a definite factor in the improvement of "morale." Enthusiastic reports have been received from the Allotment Committees operating in all the areas.

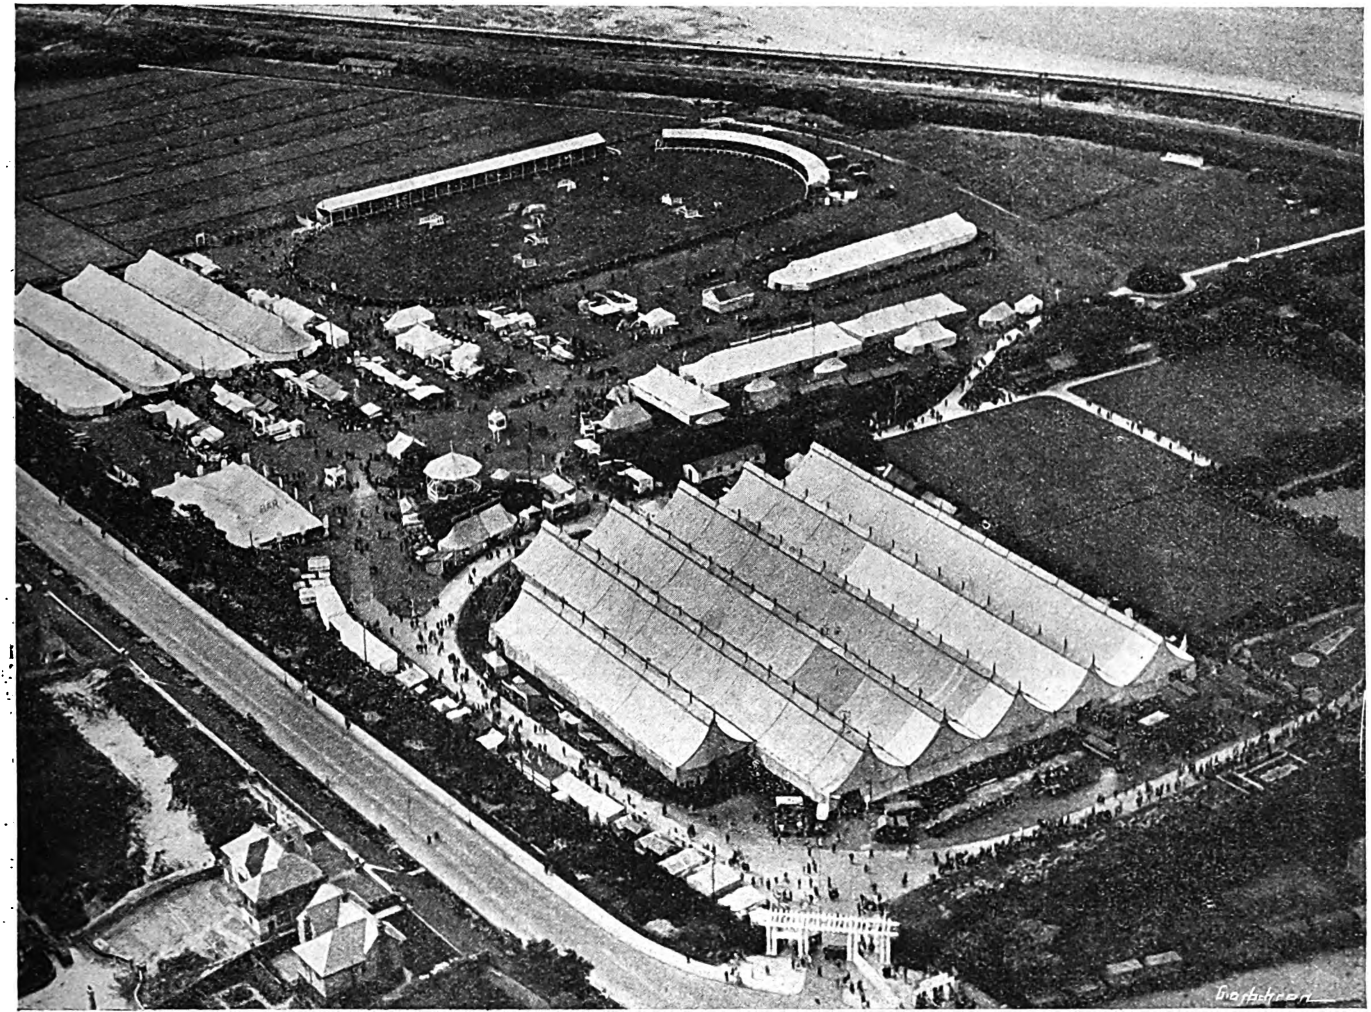


FIG. 97.—SOUTHPORT SHOW: VIEW OF THE EXHIBITION GROUND TAKEN FROM AN AEROPLANE.
(See p. 191).

Horticultural Trades Association Annual Meeting.—The Annual General Meeting of the Horticultural Trades Association will be held at Worcester on September 24 and 25, when many subjects of interest to the horticultural trade will be discussed. One resolution to be proposed is "that a Committee of Past Presidents be formed to nominate the President each year."

Masters' Memorial Lectures.—We draw the attention of our readers to the Masters' Memorial Lectures. The lectures will be on "The Relationship between Scion and Root-stock, with special reference to the Tree Fruits," and will be delivered by Mr. R. G. Hatton, M.A. The dates originally fixed for these lectures were October 2 and October 8. Unfortunately, however, through the regrettable illness of Mr. Hatton, the dates of these lectures have had to be postponed to Tuesday, November 5, and Tuesday, December 10, at 3 p.m. The Masters' Memorial Lectures were founded by the Society in 1909 in commemoration of Dr. Maxwell T. Masters, F.R.S., the great advocate of "Science with Practice," and Editor of *The Gardeners' Chronicle* from 1865 to 1907.

Appointments for the Ensuing Week.—TUESDAY, SEPTEMBER 17: Winchester Horticultural Society's meeting. WEDNESDAY, SEPTEMBER 18: National Chrysanthemum Society's Executive Committee's meeting. THURSDAY, SEPTEMBER 19: Royal Horticultural Society's Autumn Show (two days); Ipswich Gardeners' Association's meeting; Thame Show. SATURDAY, SEPTEMBER 21: Worcester Park Horticultural Society's Exhibition; Gainsborough Allotment Holders' Association's Show; Leeds Paxton Society's Autumn Vegetable Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*The Sunflower.*—Among my papers I find the enclosed—it was drawn out from information I had received of the value of the Sunflower, and sent some time since to New South Wales, where I thought it might eventually prove useful when labour became cheap, which at present does not seem very probable. It has struck me that it might be well suited for introduction into the Madeira Islands, where they require some new export, since their staple produce, the wine, is failing from the effect of vine disease. It may also serve, if my information on the subject is correct, as a material for paper-making. There is time this season to try the experiment on a small scale, from any small number of seeds and stems which you may be able to collect; and if it turns out that only one-half can be done of that which is stated, it will be useful, and worth the trial. "The Sunflower (Helianthus annus) is propagated by seed, which, sown in the spring, produces seed again in the autumn. It grows rapidly and exhausts the soil like Tobacco or any other drawing crop, and is particularly suited for woodland or rich alluvial land newly broken up, which generally renders the growth of Wheat, etc., too luxuriant for the production of seed. The plant grows large, and 2½ lbs. of seed are required for an acre of land, which it is stated will produce one-and-a-half ton of seed, two tons of stems and branches, which when stripped will yield one-and-a-half ton of silky fibre and half-a-ton of coarse fibre, and two tons of leaves. The ton-and-a-half of seed husked will produce 340 lbs. or ninety-three gallons of oil fit for table use or for lamps, as well as for machinery and manufacturing purposes. The oil is so pure and free from aqueous particles that it is particularly suited for watchmakers and all the finer parts of machinery. The seeds are also valuable as an article of food, making, when ground into flour, excellent bread, pastry and biscuits. The finer fibre of the stems is suited for making all descriptions of paper, and the coarse for the manufacture of ropes, mats, cordage and canvas. The leaves are superior green-food for cattle, and the cake remaining, after the oil is pressed from the seeds and husks, is valuable for fattening them. Any part of the plant not required for any of the above purposes yields, by burning, excellent potash for manufactures or for manure." *B. Gard. Chron., September* 16, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Duckyls Park, East Grinstead, Sussex.

Sobralias.—Specimens of this finely-coloured, large-flowered Orchid may be repotted if necessary directly the flowering season is over, care being taken to avoid injuring the fleshy roots so much as possible, especially when large plants have to be divided. As these Reed-like growers are robust-rooting plants, ample room should be allowed for development. Use well-drained pots or deep pans, with a compost consisting of equal parts of loam, A.1. fibre and leaf soil, adding crushed crocks and charcoal to keep it open. Water sparingly until the roots are moving freely in the new compost, when the supply should be increased each time the soil approaches dryness. Shade should be provided from bright sunshine and the foliage syringed frequently during favourable weather. These Orchids are very accommodating, but they thrive best in the intermediate house. During winter, less water will naturally be needed, but the plants should never be subjected to long periods of drought. Some of the older Reed-like growths may be cut out to allow more light and air to reach the younger growths.

Epidendrum vitellinum.—Both the summer- and autumn-flowering varieties of this brilliantly coloured Orchid have grown well during the bright weather experienced throughout the early summer months, especially if the plants have been able to receive the benefit of the sunlight, being shaded only during the hottest part of the day to prevent injury to the foliage. These Mexican Epidendrums revel in sunlight during the growing season, provided plenty of fresh air is admitted and a moist atmosphere maintained; the fine appearance of the pseudo-bulbs and the beautiful sheen on the foliage testify to their preference for these conditions. A position in a cool house, similar to that required for growing and flowering Cymbidiums successfully, appears to suit them admirably, for although the temperature will naturally rise fairly high with the sun-heat allowed, and extra damping is required, which, together with plenty of fresh air, tempers the heat so that only a light shade from strong sunshine is necessary. Night ventilation on all favourable occasions is beneficial, as it invigorates the plant. So long as the weather remains favourable these conditions should be maintained, with a slight decrease in the amount of damping on the approach of longer and moister nights; a little less air should be admitted if the weather turns chilly, when, however, it is better to use a little fire-heat instead of closing the ventilators altogether. As the growths advance and the flower sheaths appear on the partly-made pseudo-bulbs, ample supplies of water will be needed at the roots each time the compost approaches dryness, but later on, as the flowers begin to expand, drier atmospheric conditions should be maintained, and sufficient water only afforded to the roots to enable the buds (which continue to open for a long period) to grow and expand, and so provide a display of flowers for many weeks. After the flowers are removed and growth is complete, drier conditions at the roots should be maintained and the plants allowed a partial rest.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Fruit Tree Stocks.—Stocks are employed for various reasons, first, as a ready means for increasing a particular variety of fruit; second, to produce some alteration in the habit and bearing of the tree; and third, to fit certain varieties for some particular soil. With Apples, it has been shown by Mr. Hatton, at East Malling, that it is possible by the use of different types of layered Apple stocks, the so-called Paradise, to obtain a large measure of control over the vigour of the tree, as expressed in the amount and rate of growth, in the habit of growth and fruiting, the season of blossoming, and the age at which the tree produces blossom and fruits. It was apparent to growers for some time that, although these Paradise stocks were all reputed to be dwarfing, several types showed excessive vigour, in many cases equal to that of the free and Crab stocks. Investigations were started at East Malling, and it was found that the name Paradise had been indiscriminately applied to some seventeen different varieties. Moreover, these varieties were frequently badly mixed together and, although some of them had distinct names, these names were seldom correctly used. It required much patience and time to rogue and classify these stocks, but the result has been highly satisfactory. The first plantations of trees, worked upon this range of true, layered stocks, were planted out in the early months of 1919 and 1920, and they have already demonstrated beyond dispute that root-stock has a fundamental influence upon the whole future of the tree. For all practical purposes, only a small number of the so-called Paradise or layered stocks need be considered, and these may be grouped according to their outstanding influences, the remainder being eliminated for some fault or another. The most important types fall more or less distinctly into four groups, as follows:—(a) Very dwarfing; Jaune de Metz (Type IX), which is specially suitable for cordons, pot fruit trees and bush trees for small gardens; owing to the nature of their roots they must be permanently staked when grown in the open. (b) Semi-dwarfing; the Doucin (Type II), suitable for strong-growing dessert varieties in bush form, and where early fruiting is desirable; weak-growing varieties, such as Cox's Orange Pippin, Langley Pippin and Lane's Prince Albert, should not be worked on this stock, the cordon form being excepted. (c) Vigorous; Broadleaved English Paradise (Type I), suitable for weak-growing varieties, and large bush trees, or even low half-standards. (d) Very vigorous; represented in the Malling selections by Types X, XII, XIII, and XVI. These are apparently sufficiently vigorous and well anchored to support and develop good standard and half-standard trees. Such a grouping does not imply that other desirable stocks may not be found combining characteristics, but it is an indication of the best use to which readily available material, already in circulation, can be put. Accumulated records have so far gone to show that by a correct choice of stock a strong-growing variety, such as Bramley's Seedling, can be relatively dwarfed and brought into bearing at an early age; or, conversely, a weak grower, such as Lane's Prince Albert or Cox's Orange Pippin, can be invigorated. The nature of the soil should have an important bearing in the choice of stocks for Apple trees. Thus, a variety worked on Type II and planted in a good medium loam, may be a success, but a complete failure if planted in a sandy loam. It would appear that the more fertile and holding the soil, the more need there is for the less vigorous stocks, while the reverse holds good for the sandy soils.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Richardia africana.—Where Arum Lilies were planted out-of-doors as advised, they should now be lifted and potted. The receptacles used will depend on the grower's requirements. If large specimens are required they are best placed in a twelve-inch pot while, on the other hand, if smaller plants are the most useful place strong, single crowns in six- or seven-inch pots. A few days before lifting the plants they should be well watered and cut around with a spade; in the meantime, prepare the compost and receptacles for their reception. Richardias are gross-feeding subjects and require a rich compost, which is best supplied by adding well-decayed manure to the potting soil. If, by chance, the plants have been rested in the receptacles in which they were grown last season, no time should be lost in turning them out and repotting. Careful watering is necessary for a short time, but when in full growth Richardias respond to liberal supplies of liquid manure.

Violets in Frames.—Runners planted out in borders last spring have made excellent plants in spite of the abnormally dry season. They should now be lifted, with good balls of soil, and transferred to their winter quarters so that they may become well established before the short days set in. The frames should be in a position where the maximum amount of light and sun is secured, and, if possible, in a well-sheltered corner, protected from cold winds. Violets resent coddling, hence the necessity for planting them in a sheltered position where the frame lights can be removed entirely in the day-time in other than wet or frosty weather. The plants that are to be lifted should be well watered at the roots the day previous, and again after planting. If the weather is hot and dry, shade them for a few days to prevent flagging. Plants showing leaf-spot should have their foliage sprayed with Bordeaux mixture; if treated now many anxious moments during spells of damp weather will be saved.

Lifting Plants—Bouvardias, Salvias, Solanums and other plants which have been grown out-of-doors during the summer, should now be lifted and potted. The roots should be cut around with a trowel and the soil given a good soaking a day or so previous to lifting them. If prepared in this way they will experience very little check when lifted and placed in their various-sized receptacles, provided they are kept well sprayed and shaded from bright sunshine.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Pot Vines.—Those intended for starting early in December should now be nearly ripe; they do not require much water after the foliage is on the turn, but the balls of soil should be packed round with some material to keep them from shrinking from the sides of the pots. The canes cannot be too well ripened, and this should be properly performed before the leaves fall, to secure a season of perfect rest by keeping the canes dry and cool. If all laterals have been removed, shortening back to the proper length may well be delayed for the present. Young canes from eyes inserted this year will also soon be ripe and fit for removal to a light, airy vinery, or they will do equally well against a south or west wall. Like the preceding, they should not be allowed to lack water, hence the importance of plunging them in some light material that water will pass through freely.

Winter Cucumbers.—Where a steady supply of Cucumber fruits throughout the winter is required, the month of September must be devoted to the preparation not only of the plants, but also of the pits which they are to occupy. Remove any old soil, then thoroughly cleanse the house, washing the walls with hot lime and sulphur. Fermenting material may act for a time in place of hot water, moist heat being so essential; heat from hot-beds, with sun-heat, should be equal to the maintenance of a bottom-heat of 80°. If the compost is heavy it may be corrected by the addition of rough charcoal, lime rubble, and, if poor, by a little soot and bone-meal in preference to organic manure.

Pot Figs.—The earliest trees for forcing next season should now be reaching maturity, therefore give every attention to watering and syringing until the foliage falls naturally. After the wood is matured, stand the trees out-of-doors in a sunny, sheltered position until the first appearance of frosts, keeping them clear of the ground, or on a hard base free from worms.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Narcissi.—The earlier these beautiful bulbous flowers are planted the better the results will be the first season. The best of the commoner or less expensive kinds should be planted by the thousand on grassy banks or in the woodland where they will be seen to advantage when in bloom in spring. When naturalising Narcissi in grass endeavour to plant them as irregularly as possible; to attain this it is a good plan to throw the bulbs down in handfuls and plant them where they fall. Do not plant too closely; remember they are expected to grow in such positions for years without being disturbed, and if planted closely they soon become over-crowded and weak. In preparing positions for the rarer or more expensive varieties it is well to bear in mind that no manure should be used in a raw state; they delight in deep, rich soil of a loamy nature, which ought to be well prepared some time before planting. The smaller-flowered species are delightful plants for the rock garden, and pockets of specially prepared soil should be made for their reception. Among such are N. Bulbocodium, which likes plenty of moisture during winter and spring, and grows and naturalises itself freely where conditions are favourable; N. cyclamineus, which prefers a compost of peat, with plenty of moisture during the growing season; N. juncifolius, a tiny but attractive plant with small, Jonquil-scented flowers; and N. triandrus, of which there are many forms, and which is delightful either in pockets in the rock garden or on grassy banks. Where possible, it is advisable to plant a carpet of some low-growing alpine over these bulbs to prevent the flowers being spoilt during stormy weather in spring.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Mustard and Cress.—Where frames are available with the soil close up to the glass, seeds of Mustard and Cress may be sown in them every week; failing this, they may be sown in boxes. Radishes may also be sown in frames, which should be kept close so as to maintain a steady temperature, which, provided the soil is not allowed to become dry, is conducive to rapid growth.

Brussels Sprouts.—Late Brussels Sprouts should have earth drawn up to their stems to secure them against being blown over by wind; if the plants are extra tall, stakes should be provided for their support. If the weather continues dry and the Brussels Sprouts are in soil of no great depth, it may be necessary to water them well.

Dwarf Beans.—If plenty of nine-inch pots are available, fill them with good loam to which a little leaf-mould and sand has been added, and place six to seven Beans in each pot. Stand them outside for two or three weeks, when the Beans will germinate freely. When germination has been completed, transfer the plants to a warm house; these will supply nice young Beans when the outdoot plants have been destroyed by frost. Sow a variety such as Canadian Wonder, which is very reliable.

Endive.—Plants of this salad which were planted early are now of a fair size, and the largest may have the leaves tied up around them to bleach the hearts. Pots placed over the plants will bleach them satisfactorily, but they should be examined at intervals, as Endive is very liable to damp off quickly, especially on damp soils.

Tomatos.—Outdoor plants have set their fruits well and these are now swelling, and it will be found advisable to trim off portions of the leaves so as to allow the sun to ripen the fruits. An application of Clay's fertiliser will be beneficial to the plants at this stage, when every assistance should be given to assist them to ripen their fruits so early as possible.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Onions.—Even in late districts the lifting and drying of Onions should not be delayed or a second growth may begin, owing to the excessive rainfall, and the keeping qualities of the crop suffer. A dry day should be chosen and care exercised not to bruise the bulbs. If spread out on wire-netting raised above the ground, with a sheet of galvanised iron to throw off the rain, the ripening process will be completed in good time; or the Onions may be tied in bunches and suspended, or laid out on the floor of an open shed if desired, for so long as no dampness reaches them and air circulates about them they should finish well; on no account should they be left to dry on the ground.

Vegetables.—On heavy soils the ground has become very sodden by reason of the excessive rainfall of the past few weeks, and no opportunity should be missed of breaking up the surface when dry, as growth is negligible otherwise, and owing to the diminished sunshine, crops are not making the progress one would like.

Sweet Peas.—Plants for flowering indoors in spring should now be sown, and if space permits, the whole crop for next season should be sown at the same time, as spring-sown stock is never so successful as autumn-sown, which may safely be planted in their flowering quarters early in March, and while not showing much top growth for a time, the rooting process goes on apace. Boxes of light, loamy soil should be used for sowing, and the seeds placed in rows at least one inch apart and covered with fine soil, which should not be pressed down, the firming being done before the seeds are sown. Should the soil be dry, afford water; place in a cold frame, and cover the boxes with sheets of glass. When the seeds germinate, remove the glass. If the weather does not allow of them being uncovered, keep the plants close up to the frame lights. When two leaves are made remove the growing point of each plant, and when well broken, pot them singly into two-inch pots.

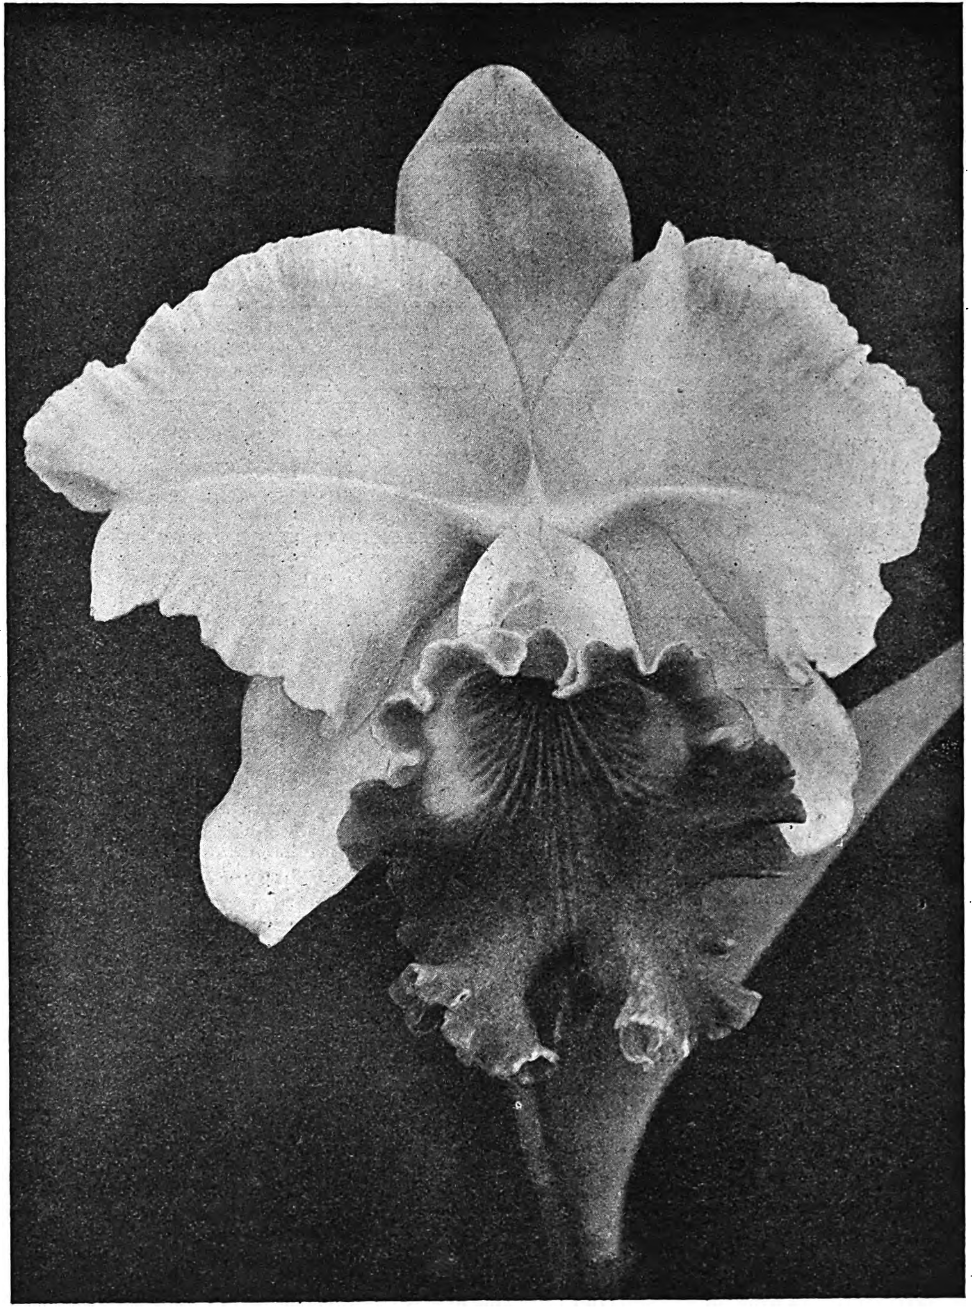

FIG. 98.—LAELIO-CATTLEYA TITYMONA VAR. ROTUNDA.

R.H.S. Award of Merit, August 27. Flowers rose-lilac and velvety, reddish-purple. Shown by R. Paterson, Esq (gr. Mr. A. Merry), Ardingly, Sussex.

(see p. 174.)

INDOOR PLANTS.

PLUMIERIA BICOLOR.

Introduced from the north of South America about the year 1815, P. bicolor, belonging to the Natural Order Apocynaceae, is quite one of our most handsome stove plants. The genus commemorates Plumier, a noted French botanist.

The rather waxy, trumpet-shaped flowers are a fine yellow, gradually shading to pure white at the edges of the petals, which are five in number and overlap. The complete flower is about two inches in diameter and delightfully fragrant. Between twenty and thirty blooms are borne at the apex of the growing stem in a cluster. They do not all open at once, in fact, five or six may be fully expanded while some are still tiny buds. They remain open about four days before falling off.

P. bicolor is a very useful subject to grow, as it provides a succession of bloom over a considerable period. The strap-shaped leaves are about twelve inches long and one inch wide, forming a rosette below and around the inflorescence.

To propagate this beautiful plant, cuttings of well ripened shoots should be inserted in sand during spring and given a little bottom-heat. When rooted, grow them on in a compost consisting of good loam, some fibrous peat and sharp sand. During the winter months they need a lower temperature, and water should be applied sparingly to the roots, only enough being given to prevent shrivelling.

With the return of warmer days, the plants will show signs of life again, and should be repotted if required, and given a higher temperature and an increased supply of moisture. When in full growth, an abundance of water is essential to the plants' well-being. *F. H. Wright, Cambridge Botanic Garden.*

FLOWER GARDEN.

EFFECT OF THE DROUGHT ON HARDY FLOWERS.

The long sustained drought of the present year has given some remarkable evidence of the very small amount of moisture which many plants can exist on, and the very great effect of such moderate falls of rain as we have experienced. I am dealing with a garden where watering on a reasonable scale was impossible, and none whatever was done. Such crops as Strawberries and Raspberries came to an abrupt end for lack of moisture, and Plum and Apple trees show unmistakable signs of thirst; moreover, the meadows around show, both in quantity of hay crop and aftergrowth, the paucity of the season's rainfall. Yet the flower garden has been brilliant throughout the season, and failures owing to drought have been fewer than the exceptional successes which may be put down to the hot, sunny days.

Perennial plants, while affected to the extent of being below average height, lost nothing in floriferousness. Few plants feel the drought so keenly as the Phloxes, and at the end of the hot spell in July it appeared as if they were drying up. The return of cooler weather, and the light rain early in August, revived them like magic, and the display has been, and still is, quite up to the average. Two very fine perennials, Scabiosa lutea, and Centaurea macrocephala, defied the hottest days of July and bore hundreds of their conspicuous yellow flowers. Not unexpected failures were those waterside plants, Lythrum and Spiraea. It is only in a year of considerable rainfall that they are at home in the border.

The handsome, old Bergamot, Monarda didyma gave an unusually brilliant display. Gypsophila paniculata and various Statices have suffered in no way, in fact, rather the reverse. Anchusas have reached their usual height and flowered well. Roses have been very good and growth remarkably free from pests. Probably winter spraying with a tar-oil wash accounts largely for this. Perennials in full flower now, or showing signs of promise in the near future are Artemisia lactiflora, five feet high and masses of white plumes, quite the most showy plant in the borders; Helianthus, Heleniums, Michaelmas Daisies, Pentstemons, unusually brilliant this year; and Rudbeckias.

Among annuals, outstanding successes have been Bartonia aurea (Mentzelia Lindleyi), Phacelia tanacetifolia, Delphinium, Jacobaea, Whitlavia gloxinifolia—never a success in a wet summer; Candytuft, which has surpassed anything I have seen it do before; Antirrhinums and Gilia capitata. Clarkias generally grow too lanky and soft to be really ornamental, but this year these defects were not evident, and the growths were wreathed in flower. Lavatera was really lovely, and, incidentally, I discovered what a fine plant it is for cutting. Flowers in vases lasted over a week indoors, and buds opened in water and surpassed in size the flowers in the borders. Phlox Drummondii and Coreopsis Tiger Star are still very showy, while Asters are uncommonly good. Of Ten-week Stocks, one batch was a great success, but a second lot, planted a week later, were a failure. Clearly just that extra moisture which the earlier plants secured, for a start, made all the difference. Nemesias, after a brilliant display, practically gave up, but have now, with the cooler and moister nights, again become decorative. Zinnias, after disappointing expectations in their early days, have lately come on amazingly, and are now brilliant.

Schizanthus pinnatus, with lilac and purple-spotted flowers, made a great show from mid-June to the end of August. Planted some distance from a border of Nepeta Mussini it overgrew that plant completely, even extending its flowering shoots well over the grass edging. A moist summer would, I imagine, result in prodigious growth and few flowers with this beautiful subject. The annuals which may be stated to have failed owing to drought are, Nigella, Sweet Peas, Calendula and Chrysanthemums. These are all plants which produce enormous numbers of seed vessels, which one is aware should be picked off. They gave a brilliant display which was short-lived, but which might have been considerably extended had more attention been given them.

Taking the season all through, it has been really successful, and I feel convinced that the artificial supplying of water would not have greatly enhanced the effect, certainly not commensurate with the labour involved. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

HARDY FLOWER BORDER.

STOKESIA CYANEA.

Stokesia cyanea, a practically hardy perennial belonging to the Natural Order Compositae, was named in honour of Dr. Jonathan Stokes, and was introduced from Carolina in 1766. The long duration of its magnificent, fringed flowers should obtain for it a place in both garden and greenhouse.

The flowers, blue in colour, are from two to four inches across, and are borne terminally to the height of up to two feet on downy stems. The involucre is sub-globose, the outer scales being lengthened into a leafy, toothed appendage, while the inner ones are lanceolate and entire. The ray florets are narrowly five-cleft, and the pappus is of one row of membranous scales. The leaves are alternate, smooth, lance-shaped, and either entire or toothed at the base, the lower leaves being petiolate and the upper amplexicaule.

Grown as an outdoor plant, this beautiful perennial requires a warm, sunny position in which it will commence to flower in July and continue to give a very pleasing display until well into September. In very cold districts it needs winter protection.

Propagation may be effected by seeds or by division in the spring. *Reginald E. Moore, University Botanic Garden, Cambridge.*

CEPHALARIA TATARICA.

There is always room in a garden of any size for tall and effective plants of distinct appearance, and Cephalaria tatarica, a member of the Natural Order Dipsaceae, and allied to the Scabious, is one which might be more largely employed. I have seen it named Scabiosa gigantea, but the above title is the recognised one for this effective plant.

There are several members of the genus, but the only place where I have seen what might be called a representative collection of the Cephalarias was in the Manchester Botanic Garden, many, many years ago. There was a bed containing nearly a dozen species or varieties, all with pale yellow or deep cream-coloured blooms. I went carefully through them and came to the conclusion that one of the best was sufficient for any garden, and this was C. tatarica. The late Mr. Bruce Findlay, who was then Curator, very kindly gave me a plant of this species, and I have never been without it since.

A big plant now occupies a good position in a broad border just in front of a Thorn hedge and every summer and autumn it shows to great advantage, its Scabious-like, deep cream flowers, which look one boldly in the face, showing well on their long stems, six feet high, against the dark green of the hedge. The foliage is of a pleasing green, and like the flower, resembles in general form that of such Scabiosas as S. caucasica, but much larger. Many may consider C. tatarica coarse, but, when seen at the back of a border or in the wild garden it is far from being a plant to be despised. It soon makes large plants suitable for division, and may also be raised from seeds. *S. Arnott.*

BOG AND WATER GARDEN.

MIMULUS RINGENS.

This species is the only one of its genus in general cultivation whose flowers depart from the standard reds, yellows, and allied colours. Although often described as blue, its blooms are a bluish-lavender, or violet, but none the less they strike an uncommon note by the waterside throughout the later summer, and their hue blends remarkably well with almost any of the yellows. M. ringens is a hardy North American species and one that is not difficult to accommodate.

It does not even ask such wet conditions as do most of its tribe, being content with any cool, free soil that is on the moist side during the growing season. It will prosper in sun or shade, its colour always looking better in the latter, and the rigid stems stand well erect under almost any conditions. These stems, which rise to a couple of feet, or more, are square and furnished with narrow, oblong, pointed leaves of a rich green. The flowers are of the usual Mimulus shape, over one inch across, and they are borne in succession from July to autumn. The tough, rhizomatous roots afford a ready means of increase by division. M. ringens was introduced so long ago as 1759. It is, nevertheless, quite uncommon in gardens, more so than its distinctive merits deserve.

DARLINGTONIA CALIFORNICA.

That this plant should have come through last winter in the open ground and without any protection is one of the surprises of that season of evil memory. On two occasions the thermometer (on the ground) touched zero, yet Darlingtonia californica suffered no injury beyond the tops of its leaves which were browned or shrivelled. This interesting Pitcher-plant makes leaves of about a foot in length, but I believe it grows taller in some soils. These leaves may be described as horn-like, hollow cylinders of a leathery, glossy-green, terminating in a rounded, cowl-like head which is often tinted with purple. Beneath this rather awesome-looking hood is the mouth of the "pitcher," and this is rendered still more ominous in aspect by the possession of two flapping ribbons of purple which hang like the tusks of a walrus from the monster's lips. The flowers are a deep blood-red and they are suspended in a canopy of green sepals at the tip of a stalk nearly two feet tall. I opened some of the old "pitchers" of this plant and found they contained an enormous number of insects.

Dr. Hill, of Kew, was kind enough to have one or two of the Darlingtonia's last autumn "catch" sorted out, and an entomologist of the Natural History Museum, South Kensington, who carried out the gruesome task, tells me that the remains of the gourmand's banquet consisted of a large number of wasps, Vespa rufa and V. vulgaris, and besides a quantity of flies, including Syrphus balteatus, blue-bottles, and others, there were remains of earwigs, caddis-flies, moths, ants and other small game. Oddly enough, there were living fly maggots feeding on the debris of their departed parents. Since each "pitcher" would contain several hundreds of insects, all probably trapped during the last weeks of autumn, a plant with twenty or thirty of these lethal chambers must account for a vast number in the course of a season.

For a few years I had D. californica close to the water in a medium, but, of course, wet loam. There it lived but did not flower. It was then moved to slightly higher ground and given better drainage, consisting of stones and rotted vegetable refuse. This had the effect of causing it to flower the first season, and it has done so each spring ever since. D. californica is, if one can apply the adjective to such an ogre, a prettier and more interesting plant than the hardy Sarracenia purpurea, which is growing under similar conditions. *A. T. Johnson, North Wales.*

ALPINE GARDEN.

VERONICA LYALLII.

In the course of 1928, a good friend sent me cuttings of Veronica Lyallii, and these proved to be very easy to strike in sand in a frame, kept close for a week or two. The resulting plants have grown well and withstood the trials of the past winter, and have been flowering freely for a couple of months or more. Acting upon the maxim "never to put all your eggs into one basket," one good plant was placed on the top of a low, double wall flanking a flight of steps, where it has as a companion Pentstemon Davidsonii and other subjects. Several others were planted near the top of a high, rock garden bank facing north-west, and others in a south border. Not one plant perished, and all have been flowering freely.

V. Lyallii is a very neat little shrubby Veronica about six inches high, and has a plentiful supply of charming white flowers with a veining of pink. Farrer states that V. Lyallii is a smaller and more prostrate version of V. Catarractae, but it is very distinct from the form of V. Catarractae called diffusa, which I grow here. V. Lyallii is not so free-flowering, but is worth growing all the same, and forms a nice, showy bush with neat, toothed leaves. It is about six inches high.

V. Lyallii is stated to be very variable According to Farrer, V. Lyallii of the *Botanical Magazine*, t. 64,456, is a more erect grower with bigger flowers and larger, egg-shaped and pointed foliage.

SILENE QUADRIFIDA.

Although a plant which is far from rare in the limestone districts of the Alps, Silene quadrifida is not so common in gardens as one might expect. Sometimes one finds that S. alpestris is substituted for it in nurseries, while the true plant is also known as S. quadridenta, which the late Reginald Farrer appears to have considered synonymous. S. quadrifida is a neater plant than S. alpestris, although I should not like to hazard a statement that it is one which should be grown in preference to that good Catchfly. I always consider the latter one of our best plants for the rock garden.

Yet S. quadrifida is a charming little species, whose nearest rival in beauty is the lovely S. pusilla. S. quadrifida naturally frequents cool, shaded places in the limestone rocks and pathsides. In the rock garden it ought to have cool, shaded nooks or crevices, with the addition of some lime to the soil of loam and leaf-soil, which it seems to love. There, when established, it is charming with its thread-like growths, furnished with narrow, green, glossy leaves and bedecked with delicate stems carrying throughout the summer lovely gem-like, pure white flowers, each petal having its margin decorated with four little teeth. There is a slightly larger form of this with rose-coloured flowers, but this is very rare, and is one which I have not the good fortune to possess. According to Farrer, this is named S. q. var. pudibunda but I think it may be synonymous with S. q. var. rubicunda.

Given a cool, moist spot, there is little difficulty in growing S. quadrifida, even in lime-free soil. It is propagated by cuttings, seeds, or division. *S. A.*

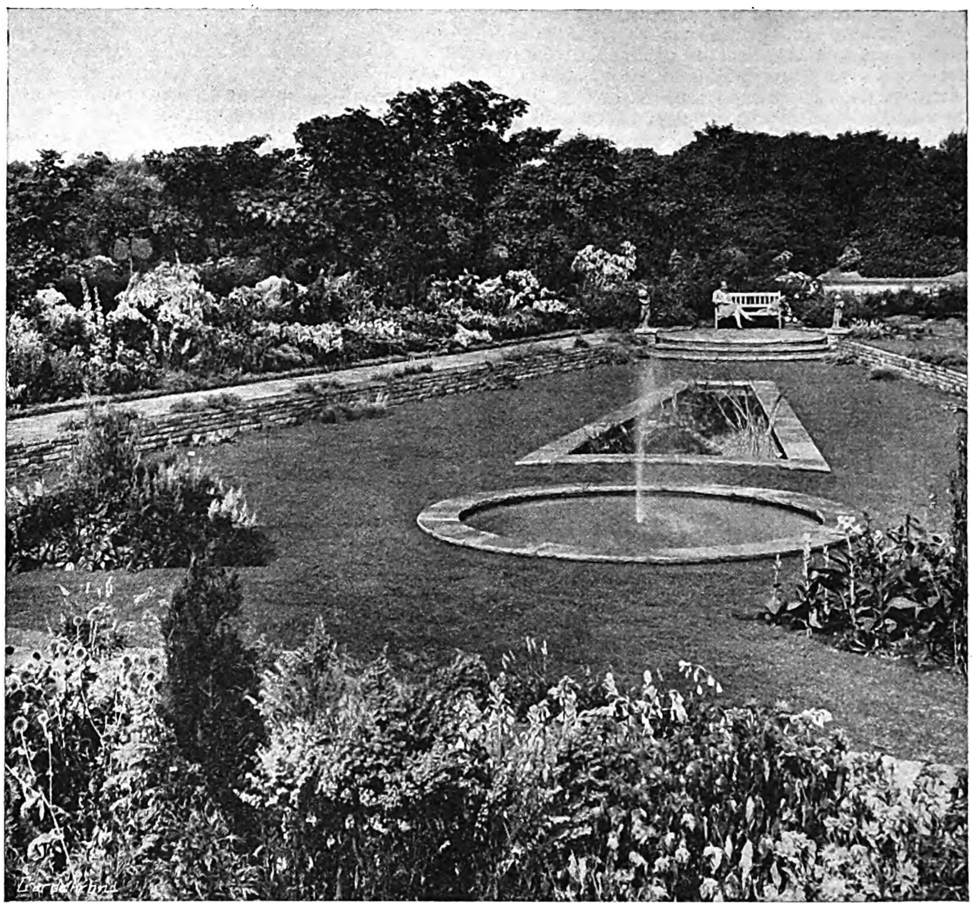

FIG. 99.—SOUTHPORT SHOW: MESSRS. KENT AND BRYDON'S FORMAL GARDEN.

(see p. 194).

DAPHNE BLAGAYANA.

One of the most entrancing dwarf rock garden shrubs which flower in early spring must assuredly be Daphne Blagayana, a species which is grown by (or is familiar to) so many professional and amateur gardeners, that a description here is hardly necessary. D. Blagayana owes its popularity to the possession of several distinctive qualities. It is both beautiful and fragrant in bloom; it is naturally hardy in a suitable situation, and until a few years ago it was considered a difficult subject to grow successfully, a fact which would be sufficient to secure the interest of any enthusiastic gardener.

Although rather exacting as regards position, soil, drainage, etc., this Daphne may become almost luxuriant when given conditions which suit it, and once in blossom the plant well merits the anticipation involved in waiting and watching. Even were the terminal heads of waxy, cream-coloured flowers, set against the background of dark green, leathery leaves, not attractive in appearance, their delightful fragrance—a fragrance peculiar to most Daphnes—is sufficient reward for the trials and failures which so frequently attend the cultivation of this species before success is attained.

On January 8, 1926, I noted that the plants of which I then had charge in Sussex had been in bud for several weeks, and were on that date "showing colour." The specimens referred to were planted on a shelf facing south-east and half-way down a cluster of large sandstone rocks. The ledge was about a yard in length and some eighteen inches wide. Although partly shaded by shrubs, it received a portion of the day's sun during spring and summer, a large specimen of Rhododendron obtusum var. amoenum protecting the Daphne until the heat of the day was spent. The compost was sandy peat, and it was found necessary to top-dress the plants every year. This annual top-dressing was important owing to a certain amount of soil being washed off the ledge, exposing the roots, which is usually fatal to D. Blagayana. Another very necessary procedure was to supply the plants with lumps of sandstone, which were laid on the soil or added with the top-dressing. The removal of these pieces of stone caused disastrous results; apart from retaining the soil in position, they evidently absorbed moisture, helping to maintain a cool root-run, and, conversely, encouraged free drainage by keeping the compost open. It may be noted that the flower buds of D. Blagayana are slow in opening, for the above plants were not in full bloom until the first week in March.

The success which attended the culture of D. Blagayana in Sussex led to somewhat similar treatment, but not on a rock shelf and with the aspect reversed, in a garden on the Cheshire-

Derbyshire border. A small specimen was planted some three years ago in a sheltered position at the base of a boulder facing north, and close to a plant of Philesia buxifolia. The compost is sandy peat and stones, and top-dressings of the same material have been added periodically. The plant has increased by running along underground (or on the surface unless top-dressed), and throwing up young growths some distance from the original specimen. It flowered freely in early April, being a little late owing to the season and aspect. Except in very favoured districts it is desirable to give a position facing north, if sheltered, in order to ensure that the flower-buds do not open until risk of frost-damage is at a minimum.

According to the late Reginald Farrer, D. Blagayana is a plant which is typical of the eastern alpine screes. He recommended a compost of stones, loam, peat and sand, but it may be argued that the addition of loam is not essential. Many growers succeed with the plant, and yet use little or no loam in the actual compost. Others add leaf-mould; this is admissible in moderation because of its chemical content and moisture-retaining properties, but the species appears to be unconcerned whether it has leaf-mould or not. It would appear that the chief essentials are a moist, yet well-drained, cool rooting-medium with plenty of large stones, annual top-dressings which will cover the leafless lower parts of the running stems, and light shade from the hottest sunshine. The writer has not found D. Blagayana to be intolerant of small quantities of lime, but it grows equally well in a lime-free compost.

Farrer waxed eloquent over the stony treatment of this species. While his advice to throw stones at the plant whenever one passed it, need not be taken literally, experience has proved the element of truth behind the remark. *L. B. C.*

SEDUM PILOSUM.

The hot, dry weather of the past spring and early summer has been very trying to plants in rock gardens, even where sprinklers and the hose have been employed. Had the prolonged frosts been accompanied by heavy snowfalls, and succeeded by warm, sunny conditions with fairly abundant precipitation at night, the rock gardener would have been overjoyed. A drought in spring is almost as serious a matter as excessive atmospheric humidity in winter; it would be equally as serious but for the fact that a drought can be remedied, although it may entail much labour and expense at a time when other parts of the garden require attention.

However, there are some plants which have thoroughly enjoyed the dry season, and probably none more so than the Sedums and Sempervivums. Of these, Sedum pilosum has been especially glorious, appearing to revel in the most sun-baked positions on the rock garden. In a recent number of this journal (*Gard. Chron.*, June 15, p. 441), Mr. J. W. Besant accorded this species a few words of well-merited praise.

Unfortunately, S. pilosum is a biennial. In its first year it forms small, tight, incurved rosettes of downy, apple-green leaves. These rosettes will produce offsets which may lead to premature hopes of rapid and perennial growth; but this is no true criterion, for the plant starts with the precociousness of a weed and then abruptly ends its existence after flowering. In May and June of the second year the rosettes are prolonged into short, stumpy, fat flowering stalks, one inch to three inches in length, closely set with hairy, succulent, linear-spathalate leaves, and producing several crowded apical branches. These little branches then erupt into flower in such profusion that the plants resemble squat clubs of clear, sparkling rose-pink, the petals being of waxy texture and thus reflecting what would otherwise be a softer tone. The plant is astonishingly like some miniature Crassula, but there are several conclusive botanical differences. To quote the late Reginald Farrer, S. pilosum, when in flower, is "much more suggestive of a Kalanchoe, from Fairyland, than anything else we know in this unrefined family."

This charming species hails from western Asia Minor, occurring in Armenia and the Caucasus at an altitude of 4,000 feet to 5,000 feet. It was named by Marschall von Bieberstein in 1808, but has been grown in gardens under the invalid name of S. Regelii. For one hundred years after it had received botanical recognition S. pilosum remained unknown as a garden plant in Britain. In 1910, Regel and Kesselring distributed seeds from Leningrad. A photograph appeared in *Gard. Chron.*, 1911, Vol. I, Fig. 160, on the occasion when it was shown at the Temple Show by three well-known nursery firms, one of which, the Burton Hardy Plant Company, supplied the plant which, was figured in the *Botanical Magazine* (t. 8,503).

In the article which accompanied the photograph in this journal, it was remarked that "Pink is such a rare colour in Sedums that any addition to the number with flowers of this colour is very welcome. Two of the smaller-growing species with similar coloured flowers are S. pulchellum and S. Sempervivum." Lest this statement be taken literally, one may add that the biennial S. Sempervivum (S. sempervivoides) is scarlet in colour, and the present writer is under the impression that it is a more lax and slightly larger plant; while the true S. pulchellum has rosy-purple flowers, and is a perennial species from the United States. S. sempervivoides is native to very much the same geographical area as S. pilosum, and the differences between the two species are so slight that it would appear legitimate to argue that the subject of this note is simply a form of S. sempervivoides, with S. indicum forming the Himalayan link between the Western and Eastern sections of the group sempervivoides of Dr. Lloyd Praeger. As Dr. Praeger points out in his Monograph, S. indicum is a variable plant, but always biennial and showing a closer affinity to the Asia Minor section than to the Chinese representatives of the group. The writer has not seen this species (S. indicum) as a garden plant, and the descriptions do not indicate any particular attraction for such a purpose. It does not appear in the Kew *Hand-list of Rock Garden Plants*; neither does Farrer record it in his *English Rock Garden*.

To return to the subject of this note. S. pilosum offers little difficulty in the garden. It loves a hot, fairly dry, stony soil, with a southern exposure, and may be planted (or perhaps sown) in broad, sweeping drifts, in clustered colonies, or dotted here and there on the rock garden. The latter method probably supplies the most natural effect, where it can make spots and splashes of pink on some stony slope; it may even be grown in clefts in the rockwork, and will flower with equal precocity in such situations. Seeds are produced freely and germinate readily, but the writer has not yet tried sowing *in situ*, since the plant is so useful for sowing under glass and then dibbling into odd corners or bare spaces as required.

Two rosettes of S. pilosum were obtained in 1927. They flowered the first year, being then in their second season of growth. From these two rosettes seeds were saved and sown in August (1927). At least a thousand seedlings appeared and about two hundred were planted out at the end of March, 1928. The soil was ordinary strong loam on top of a bank facing south, and the plants were dotted about in bays and between stones. For some time the rosettes failed to make headway. The spring was cold and dry, and these conditions extended into early summer. When the rain came the rosettes increased, often producing three (rarely one or two) rosettes from each parent, but they did not flower. A few of the rosettes were slightly damaged by wet, but otherwise the plant appears to be quite hardy. The chief difficulty is that the rosettes are pulled out of the soil by birds(?). In May and June of this year (1929) the plants flowered profusely—*i.e.*, about one year and nine months from sowing. Incidentally, rosettes of S. sempervivoides, purchased in the spring of 1927, and planted out in a similar position to that afforded S. pilosum, did not flower until August, 1928.

There is yet another way of growing S. pilosum. For the alpine house it is a thing of remarkable luxuriance and beauty, and may be recommended as a most decorative room plant during the few weeks it is in flower. When grown in pots the plant loses its dwarf, compact habit, and on producing its flower-stems the latter bear their leaves far apart. It becomes a great, lax succulent of magnificent proportions, with larger and more loosely-branched flowering stems—altogether a different plant. The individual flowers also are larger, being almost half-an-inch across, whereas in the open ground they rarely exceed a quarter-of-an-inch; they are, however, paler in tone than the bright rose of outdoor specimens (although on the rock garden the colour fades with age).

Some twelve months ago several rosettes were pricked out into a six-inch pot of soil but slightly richer than that accorded plants outside. By May of this year the plants had swollen to enormous proportions. Weighed down by the immense flower-heads, the whole mass flowed over the side of the receptacle, almost hiding the pot from view; the total spread was fully fifteen inches. This outrageous specimen of S. pilosum remained in flower for three or four weeks before going pale and sickly and dying off. The excessive length of stem and looseness of head were probably due to growing the plant on the staging, well away from the glass. It is, perhaps, worth noting, that pieces falling from this plant on to the greenhouse stage immediately took root and flourished in the gravel. As some of the smaller rosettes (off-shoots from the main plant) do not flower in the year in which they are made, it is reasonable to suppose that such portions which have separated from the parent plant and produced roots of their own, will flower in the year following. This is not a perennial mode of life, since the individual rosettes have fulfilled their allotted span of life by flowering and dying in the second year of their existence. This is what happened to the majority of the subsidiary rosettes formed in the summer of 1928, the untoward season probably accounting for the unusual behaviour of the parents. *C.*

BULB GARDEN.

THE HARDINESS OF GLADIOLUS BYZANTINUS.

I have known Gladiolus byzantinus as a hardy perennial which might be left alone in the border for many years without suffering from the weather, and have grown it myself for over forty years in my own gardens. Until now I have always considered that it would be unscathed during the hardest winter we have in this climate. To my surprise and disappointment this Gladiolus succumbed to the trials of last winter, and the numerous plants I had all perished. I should be glad to hear if any other reader has had a similar experience. *S. Arnott, Maxwelltown, Dumfries.*

LEUCOJUM AUTUMNALE.

Everyone knows and admires the Spring Snowflake, Leucojum vernum, but the Autumn Snowflake, Leucojum autumnale, is not so frequently met with. It is undoubtedly a perfect little gem, attaining a height of five or six inches, and producing grass-like leaves and charming white flowers tinged with red and borne on chocolate-brown stems. It is a plant of dainty appearance and is eminently suited for a good position in the rock garden; pot cultivation is also successful. The bulbs should be planted in July in a deep, light, sandy medium, a depth of from one to two inches being sufficient.

The dainty flowers are produced at the present time—during August and September. *T. H. E.*

TREES AND SHRUBS.

CRATAEGUS TANACETIFOLIA.

Belonging to a group of eastern Thorns, (of which C. orientalis, C. sinaica, etc., are also members), C. tanacetifolia was cultivated first in 1789, being introduced from Asia Minor and Syria.

It forms a fine, ancient-looking tree about thirty feet high; with long, gnarled, crooked branches, thickly set with multitudes of small twigs—almost converting the tree into a giant Witch's Broom—on the tips of which the sweetly-scented flowers are borne freely in clusters of generally seven. They are white, or nearly so, but the stamens have scarlet anthers, so giving the blooms—I had nearly written the tree, for it is generally almost covered with flowers—a distinct pinkish tinge.

The down on both surfaces gives a pleasing shade of grey-green to the leaves, which are divided into narrow lobes by up to seven, deep, parallel cuts, slightly toothed, and glandular towards the apex of each lobe. They are nearly as broad as their length—one-and-a-half-inch—and generally obovate.

CRATAEGUS DUROBRIVENSIS AND C. PUNCTATA.

A shrub of resplendent beauty, C. durobrivensis is glorious alike in flower and fruits; the large fruits are borne in big, drooping clusters in great profusion to the tops of the angular growths, fifteen feet or more in height (armed with long, terrible thorns), and are retained throughout the winter. The leaves are also worthy of note, being of rich green all the season, until disappearing in a flare of gold during October. They are broader than those of C. Carrierei, are lobed on each side, and serrate towards the apex. This Thorn has been in cultivation since 1901, and was first found growing near Rochester on the southern shore of Lake Ontario, U.S.A.

Crataegus punctata is another fine Thorn, whose pomes do not remain for long on the tree, but cover the ground to such an extent that it is impossible to walk under the tree after they have fallen without treading on several of the crimson-brown, practically globose, spotted fruits. The white flowers are borne in large corymbs, and the leaves, which are serrate and broadly ovate, narrowing towards the base and abruptly so to the apex, are downy beneath, and gently lobed on the young, sappy growths.

The habit of the tree is good, for with its almost horizontal branches it forms a grand head. C. punctata was introduced to cultivation in 1746, and is a native of Quebec, Ontario and Georgia, and to the west in Iowa. *G. S. T.*

DESFONTAINEA SPINOSA.

Desfontainea spinosa is a fairly common shrub in the west of Scotland, and the experience of most gardeners along the western littoral will scarcely coincide with those of your correspondent, *B. O. M.* (*Gard. Chron.*, p. 109), who mentions that a specimen six or seven years old may not exceed a foot in height. In regard to flowering, I have flowered it the second season after rooting the cuttings.

Cuttings of the lateral shoots, a few inches long, taken with a heel of the older wood, root readily if taken about the present time and inserted in light, porous soil, over a slight bottom-heat, keeping the cuttings close, moist and shaded.

Apart from its decorative value in the shrub border, D. spinosa is a good rock garden subject, as witness the spreading mass in the Edinburgh Botanic Garden, where it thrives and flowers profusely. In addition to the type there is a variety, Hookeriana by name, with flowers longer, and clearer in tone. *Jonathan Fiona.*

THE GENUS PRIMULA.

(*Continued from p.* 184.)

PUSILLA (Wall). Elfin P.
(Bella).

A minute, tufted, deciduous species with dense rosettes of spathulate or broadly lance-shaped, blunt leaves from half-an-inch to one inch long; margins pinnatifidly toothed with sharp, recurved teeth; upper surface sparsely covered with short, stiff hairs, underside densely covered with whitish down. Flower stem two to three inches tall, very slender, bearing a head of one to four nearly stemless, purple or violet flowers. Corolla a quarter- to three-eighths-of-an-inch across, with spreading, oblong, or broadly heart-shaped lobes; tube funnel-shaped, hardly exceeding the calyx, with a densely woolly throat. Introduced in 1888. *Bot. Mag.*, t. 7,079.

Grows in damp, stony, alpine pastures, in the central and eastern Himalayas, from 13,000 to 16,000 feet above sea-level.

Culture: Grow it in gritty, fibrous loam and peat, in a damp, half-shady spot, with protection from damp in winter.

PYCNOLOBA (Burr. et Franch.). Wine-red P.
(Pycnoloba).

This remarkable, deciduous perennial species possesses an exceptionally long, yellowish-green calyx and comparatively small blossoms. The rich green leaves, in tufts, have broadly heart-shaped or oval-heart-shaped, somewhat blunt blades so much as six inches in diameter, borne on hairy stalks two to six inches long; margins cut into unequal lobes which are furnished with sharp teeth; both surfaces clothed with scattered white hairs. Flower stem four to twelve inches tall, stout, hairy, bearing an umbel of about a dozen claret-red blossoms. Corolla about half-an-inch across, with erect, egg-shaped, notched lobes; tube cylindrical, scarcely as long as the calyx. Introduced in 1906. *Bot Mag.*, t. 8,612.

Grows in cool, damp, shady places near Tatsienlu, in Szechuan, western China.

Culture: As for P. mollis.

PYGMAEORUM (Balf. f.). Pigmy Stemless P.
(Farinosae).

A minute perennial species with rosettes of thick, fleshy, oblong-oval, blunt leaves carried horizontally on membranously-winged, strap-shaped stalks, sheathing the short root-stock at the base, in all from half- to three-quarters-of-an-inch long; margins entire, non-cartilaginous; both surfaces more or less smooth. Flower stem about a quarter-of-an-inch tall, smooth, immersed in the foliage, bearing an umbel of about three fragrant, mauve-coloured blossoms with a tiny yellow eye. Corolla about three-eighths-of-an-inch across, flat, with wedge shaped, deeply bifid lobes; tube cylindrical, about a quarter-of-an-inch long, with an undulate, toothed ring in the mouth. Flowers from April to July.

Grows in damp or boggy places and also in comparatively dry, sandy soil, in short turf, near Kambajany and in the region of Gyantse, in Tibet, at 13,500 to 15,500 feet above sea-level.

Culture: It should be grown in good fibrous loam, sand and peat in a damp, open situation in the rock garden, or on the edge of the bog garden, but kept comparatively dry in winter.

PYROLAEFOLIA (Lévl.). Pyrola-leaved P.
(Petiolaris-Chartacea).

A little-known Chinese perennial species reaching a height of about seven inches, with smooth, nearly circular leaves, heart-shaped at the base, borne on slender, non-winged stalks longer than the blades; the margins are furnished with somewhat remote, blunt or at times, sharp teeth. Flower stems longer or shorter than the leaves, slightly downy upwards, bearing an umbel of one to twelve blue or violet blossoms. Corolla with heart-shaped, toothed, dotted lobes; tube shorter than the calyx. Flowers in April and May. Not in cultivation.

Grows in shady places on wooded hills at Chan Hien and Ou Kia, in Yunnan, at 2,500 to 3,000 feet above sea-level.

Culture: Fibrous loam and Oak or Beech leaf-soil, in a damp, cool, shady spot, with protection from frost in winter are the conditions indicated.

RADICATA (Balf. f.). Many-rooted P.
(Farinosae).

A very distinct perennial from the Himalayas, with a tuft of leathery leaves about three-quarters-of-an-inch long, with elliptic or oblong blades, rounded at the tip, tapering to a stalk, broadly edged with membrane; margins furnished with remote, coarse, hooked teeth; both surfaces pitted with glands, upper surface sparsely, underside densely coated with white meal. Flower stem obsolete; flowers four to five in a sessile umbel immersed in the foliage. Corolla about half-an-inch across, bright rose colour, with thick, nearly square, notched or deeply cleft lobes; tube narrowly cylindrical below, dilated upwards and constricted at the mouth, where there is a deeply coloured ring; throat more or less downy.

Grows in damp, rocky soil at Chitral, in the north-western Himalayas.

Culture: As for P. rosea, of which it is, according to Professor Wright Smith's grouping, a sub-species.

REDOLENS (Balf. f.). Fragrant P.
(Bullatae).

A very beautiful, sub-shrubby, more or less evergreen, non-mealy species with a much-branched, woody rootstock, clothed with the remains of previous seasons' foliage. The rich green leaves, in dense rosettes, have oblong, blunt blades, wedge-shaped at the base, gradually tapering to a scarcely winged, channeled stalk, equalling the blade in length, in all three to five inches long; margins coarsely toothed; both surfaces clothed with white, glandular hairs, upper surface very deeply veined, underside pale, reticulate. Flower stem stout, four to five inches tall, densely coated with white, glandular hairs, and bearing an umbel of about a dozen white or pale violet, highly fragrant blossoms, on erect, pale green stalks, about three-quarters-of-an-inch long, covered with glandular down. Corolla flat, nearly one inch across, with overlapping, egg-shaped, bifid lobes coated on the underside with white meal; tube cylindrical, slightly dilated upwards. Introduced in 1911.

This species is a native of Yunnan, western China.

Culture: As for P. Forrestii.

REGINELLA (Balf. f.). Reginald's P.
(Farinosae).

A beautiful, dwarf species with tufts of few, somewhat thick leaves from three-quarters-to one-and-a-half inch long, with oblong-elliptic or nearly diamond-shaped, blunt blades, usually abruptly contracted into a winged stalk about twice the length of the blade, with a cylindrical sheath at its base; margins quite entire; both surfaces sparsely sprinkled with minute, capitate, glandular hairs. Flower stem about three-quarters-of-an-inch tall, erect, smooth, bearing an umbel of about half-a-dozen bright rose-coloured or bright mauve blossoms with a rich orange-coloured eye. Corolla about three-quarters-of-an-inch across, with egg-shaped or wedge-shaped lobes very deeply cut into two elliptic segments; tube cylindrical, with a ring in the throat. Flowers from May to July. Introduced in 1916.

Grows in open mountain pastures in company with other dwarf vegetation, in Kansu and western Szechuan, at from 11,000 to 15,000 feet above sea-level.

Culture: Plant it in good fibrous loam, grit and limestone chips in an open, sunny position, well supplied with water when in growth. *A. W. Darnell.*

(*To be continued*).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXX.—Droughts and Doubts.

THREE problems now presented themselves to us: (i) the problem of food; (ii) the problem of water; and (iii) the problem of how to reach the Alps, which were some distance away. Over the first two we had little direct control, the third might be solved by perseverance. Luckily for us, it rained the very first night, and we caught some water off the tents; but during the next fortnight the drought was severe, and we were often very short; had it not been for the discovery of a muddy water-hole among the Bamboos, and later of a spring, about a mile from camp, we must have abandoned the ridge before the rains broke again. The water-hole was soon exhausted, and as the muddy water was upsetting us, perhaps this was as well. Then, on August 23, I had the good fortune to discover a small spring of clear water, from which we were able to draw a petrol-can full of water a day. Early in September, the rains recommenced, and all anxiety about water ceased.

The food problem was more serious. On August 18 we had about four days' rations—Rice and flour—left, but by reducing the ration still further, we could make this last a day or two longer. We drew in our belts and waited, but the rations dwindled day by day, and things looked very bad. On the 23rd, the last grain of Rice was finished—we ourselves had long since given up eating Rice, as we had our stores—and Luso had no food. A little flour still remained, but it was full of maggots and quite sour, so he would not touch it; we were not so particular, and had no religious or other scruples. But in spite of our stores, we were not really much better off than Luso. Rum and chocolate, biscuits and O.K. sauce, although excellent in themselves, are not a diet on which one can climb or move mountains; and when the last chuppatty and the last army ration were finished, we began to look foolish. We sent Hubble down to the valley to raid the villages, but he returned, like the dove to the ark, empty. Then we sent him down to get news of any coolies coming up with supplies; but again he returned without so much as an Olive branch. This was serious indeed, for usually when coolies are coming up the valley with loads, you hear of them days before they arrive. For three days Luso ate nothing at all—so he said—except four eggs which our friend the Meiliang Gam brought up; we insisted on him eating those. And then one day we returned to camp from a climb and found that four coolies had arrived with bags of flour and Rice; more were reported to be bringing up a fresh supply of stores. That night we went back on full rations and had a good dinner. One more day, and we should have had to return to the valley, although what we should have found to eat when we got there, goodness knows.

A short description of the forest in which our camp was situated, and where we remained for two months, may be given. The ridge ran due east to join the Dow-Delei divide, so that one flank faced north, the other south. The latter was covered with a dense growth of small trees, shrubs, bushes and climbing plants, including many Rhododendrons, Oaks, Acer, Castanopsis, Daphne papyracea (cannabina), Euonymus, Polygala arillata, Hydrangea, Buddleia, Enkianthus, Deutzia, Ilex, Salix, Rubus species, Gaultheria species, Berberis Wallichiana, a Yew closely resembling Taxus baccata, and Alnus nepalensis. Many of these are also found growing much bigger in the forest proper. Among climbing plants were species of Lonicera, Smilax, Akebia, Zanthoxylum, and Clematis montana. The Rhododendrons included R. Lindleyi, R. virgatum (the only place I saw that species), and the common 'Thomsonii,' 'Edgeworthii,' 'Maddeni' and 'Aureum' species, besides the small yellow-flowered epiphytic 'Campylogynum' with red fruits, and the gamboge-flowered 'Boothii.' On the rocky outcrops and grassy slopes which occurred here and there grew a pink-flowered Begonia with bunches of crimson fruits and rough-haired leaves, and a small Impatiens with vivid crimson flowers.

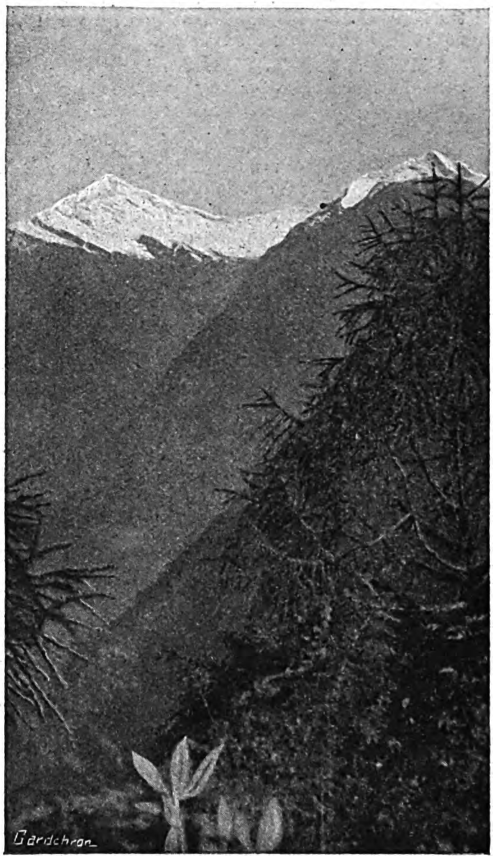

FIG. 100.—KASO: COLD AND ALOOF.
Showing the steepness of the forested slopes.

In the rain forest, on the sheltered face, were huge Oaks of many species, Acer pictum, a fine tree with dark green, seven-pointed leaves and masses of straw-yellow fruits streaked with purple, Magnolia rostrata, Betula, Pyrus species, Illicium, Tsuga, Schima, Gamblea ciliata, Rhododendron sino-grande, and several species of Cinnamomum and other Lauraceae.

In some places the ridge was deeply furrowed, and during the rains water collects in these hollows, which were always filled with a thick screen of Bamboo. The ground was very sticky, and it was here we found our water-hole. Wherever these Bamboo thickets occurred, there was certain to be found a large, spreading Magnolia, which by the end of September was covered with flower buds; but the flowers did not open before we left, at the end of October. I am informed by Mr. J. E. Dandy, to whom I showed some leaves, that this is M. Campbellii.

The undergrowth of the rain forest is mostly herbaceous, with a few small, scattered shrubs. Except where there are patches of Bamboo, it is quite easy to get through the forest, although, of course, directly we left the ridge we were on very steep slopes. Many of the herbaceous plants grow socially, *e.g.*, Ferns, species of Polygonum and Impatiens, and Strobilanthes. Other species, chiefly Monocotyledons, are more scattered, *e.g.*, the ground Orchids, Liliaceae, and Arisaemas. Among a few interesting herbaceous plants found in the rain forest were a Violet, which grew in colonies on the steeper slopes, and Androsace Henryi, both in fruit. Big climbing plants included Vitis, Actinidia, and two species of Schizandra, one with short, compact bunches of purple fruits, like small Grapes, the other with long, interrupted spikes of scarlet fruits; these last reached a length of six inches.

Soon after we had settled down in this camp it looked as though we were going to have further serious friction with the Mishmi-log. We had pitched our camp in a small clearing, and one day two hunters came up from the village on the south side of our ridge—Meiliang (Camp III) lay at the foot of the north face. Finding us squatting here, in their clearing, the Mishmis went straight off the deep end. They complained that we were trampling all over their Teeta garden, and spoiling hundreds of rupees worth of Teeta—Coptis Teeta being a small Ranunculaceous plant, the roots of which are prized as medicine. It grows wild in the forest, but clearings are made between 6,000 and 8,000 feet to promote its growth in accessible spots, and the plant is dug up in the winter and sold in the Saduja bazaar, the current price being nine rupees a *seer*, or about seven shillings a pound. The Mishmis put in a claim for large compensation, but as by this time we were thoroughly tired of Mishmi complaints, we told them to go to blazes. Mitonma, the village in question, at once declared war by non-co-operation, and refused to sell us bad eggs, or supply coolies, or help us in any way; but as we had already booked the Meiliang Gam, with heavy bribes and promises which he knew would be cashed on presentation, we felt secure on that flank. Also Chibaon, the next village down the valley, where we had stayed in April, had no quarrel with us, so that we could count at least on their neutrality, and the offended village was neatly sandwiched between these allies.

More serious was the complaint that we were spoiling the hunting rights. The Meiliangites did not hunt, so our being on the ridge was immaterial to them; also it was not their forest reserve, anyhow. But the Mitonmaites were very bitter about it, and tried to suborn our tame Gam with dark threats. But the Meiliangites, having been well paid by us, were unrepentent. True, they had been cowed by the threats of the truculent Tablekonites, whom they dared not disregard; but they could afford to listen to the vapourings of the Mitonmaites with contempt.

Where all this backstairs intrigue affected us, however, was that no one could be found to take us up the ridge to the alpine region, and although there was a track part of the way—frequently interrupted—it was very difficult to follow. Why, it may be asked, did we not simply follow the ridge, which, as we could see from our camp, joined the main divide? But it was just this following the ridge, smothered in the forest and unable to get a view in any direction, which was so difficult. As for the peak on which we had to march, it was, during the drought, often plainly visible from camp; but by the time we had cut a path to the divide, the rains had broken, and we did not see it again for five weeks.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; Sept. 7, 1929.

However, from the very beginning we set to work to cut a path along the ridge; where the forest was open and the ridge undulating, we could follow the trail, or easily make one for ourselves. It was in the dense Rhododendron scrub, and on the steep slopes that, finding no trace of any path, we had laboriously to cut our way. Several times we got right off the ridge and found ourselves cutting a path along some flank spur. Nevertheless, by September 2, when the fine weather broke up, we had taped a path so far as the main divide.

Our worst troubles now seemed to be over. We were securely planted in our new camp, a long way from the Alps, it is true, but in a better position than at one time seemed possible; we had plenty of water, and enough food to last us until the middle of October. Success seemed assured. The real knock-out blow came later, and from an unexpected quarter.
F. Kingdon Ward.

PROBLEMS OF PLANT LIFE.[*]

VIII.—Plants and Drought.

Such a season as that through which we have recently passed is one of great anxiety to the farmer and gardener. The problem is to find plants which can flourish under conditions of drought, and during the present century large sums have been expended in various countries on investigating the means which Nature employs to meet the difficulty. For while it is a comparatively modern problem with us in the British Isles, Siberia, America or Australia, it is far from being a novel problem in the realm of Nature. If we can discover a few of her methods of procedure, therefore, the knowledge gained may presumably be of great service.

One very suggestive method of meeting the difficulty is of such great importance that we place it in the forefront, because it has practical and economic significance. It is well-known that many of our native plants, relying on an abundant supply of moisture, content themselves with surface roots. They never strike deep. This, in times of drought, proves their undoing. Nature says, in effect, that the plant which will survive a long period of drought must send her roots deep. It will probably come as a surprise to many readers to learn that if grain is sown in suitable soils Oats will send down their roots to a depth of four feet, while those of Wheat have been found to go deeper still, attaining a depth of five feet. This shows the importance of deep culture—" Because they had no deepness of earth they withered away."

It follows, in the first place, that those crops are the most likely to resist drought successfully which have penetrating roots and depth of soil. In this connection it is instructive to examine such native plants as are exposed to drought through the struggle for life. Ousted from the richer soil, they gain a livelihood in dry places, and are able to flourish by means of their tap-roots. Thus, if we pluck up weeds which flourish in dry places and in seasons of drought, we shall often find that they have at least one root which can penetrate the soil to a considerable depth. The practical gardener may be reminded that we have a capital illustration in the plants which are grown for Spinach. If we compare the ordinary form of Spinach, with its shallow roots, with Good King Henry (Chenopodium Bonus-Henricus), which many people find preferable, we shall see the difference. The latter is now often found as a weed outside old-time villages, and has a very deep root.

Take next the problem of sap. It used to be thought that the flow of sap was a very simple matter. As knowledge widens, however, we find that there are numberless problems to be solved in this connection. Most plants, as is well-known, are supplied with abundance of breathing pores or stomata. We will consider these important organs in my next paper. They vary immensely in size, number, shape, arrangement and position, and are thereby able to serve a variety of ends. Under the influence of sunlight they take in the carbon dioxide given off by the lungs of animals and men, filter out the oxygen and use up the carbon. They are also useful for purposes of transpiration.

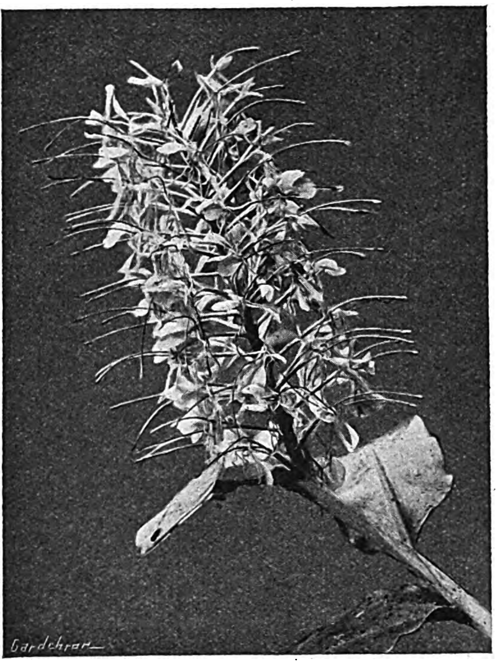

FIG. 101.—HEDYCHIUM SP. (K.W. 8,501).

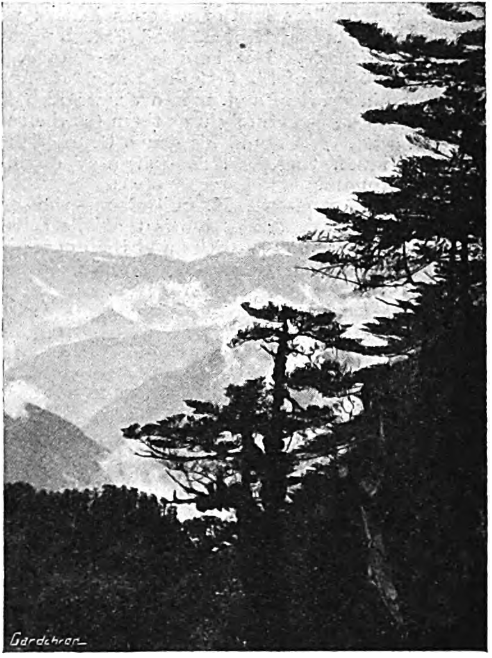

FIG. 102.—ABIES WEBBIANA AND THE VALLEY DEPTHS.

Now the moisture in the soil is drawn up through the combined action of root and leaf, the plant is rendered rigid, the salts held in solution in the water are distributed by a wonderful process of selection and, along with the carbon, converted into stem and leaf, flower and fruits, with all their various colours, shapes, perfumes, oils, essences and other qualities.

It follows that if one would understand the means by which Nature balances her accounts, special attention must be given to the processes of transpiration, with which I dealt in my sixth paper, and wilting, which was the subject of the fifth. Wilting serves the plant-grower in two ways. It helps to eke out diminished supplies, and it hangs out a flag of distress.

Wilting, however, is only one of the many processes brought into operation to check transpiration, and thus diminish the effects of drought. Everyone who has studied the plants which are normally found in this and other lands growing in dry places, or flourishing under drought conditions, knows that they are frequently found to be provided with a waxy coat, a garb of special hairs, and other ingenious devices for keeping the flow of moisture within due proportions. It follows that, if one wishes to grow plants which will not succumb to drought, choice should be made of those species which have been specially provided by nature with such devices as these. Some plants secure the end by developing a specially thick cuticle, others by reducing the number of stomata, or by placing them in unusual situations to check transpiration.

It is very instructive also to notice the ingenious plan of providing plants with natural tanks or reservoirs which can be filled in days of luxury and prosperity, to be drawn upon in seasons of adversity and need. The roots, bulbs, corms, tubers and other underground organs with which so many plants are provided are in many instances clearly designed to meet emergencies, such as follow a period of drought. Swollen stems, thick leaves, succulent fruits are other well-known devices familiar to every practical student of plant life.

Persons who have the care of lawns can hardly have failed in seasons of drought to observe how fresh and vigorous the Clover is when the grass has lost its freshness and bloom. This leads us to another of the many means which Nature employs to meet her needs. It has long been known that certain plants, by an ingenious means of subsidizing soil-bacteria, are able to obtain rich supplies of nitrogen and so flourish when other plants succumb. Taking advantage of this fact, growers in other lands have developed the cultivation of such plants in order to secure themselves against the losses which they might otherwise sustain.

It may not aid the gardener or farmer, perhaps, in any very practical way if he devotes attention to the life histories of Lichens, Mosses, Lycopods, Ferns and other related plants which are able to live and flourish in times of drought, but the student of plant life will pursue this line of investigation for the light which it throws upon the problems which Nature undertakes to solve. For, great as have been our advances during the present century, much still remains to be learned.

One might enquire, for example, what difference it makes to a plant whether its cell sap is watery or milky, thin or concentrated, free from, or largely impregnated with, various acid or alkaline, oily or aromatic ingredients. How far does the gum of the Acacia, the turpentine of the Pine, the tannin of the Oak, or the milk of the Spurge affect their powers of drought resistance? One might surmise that the thin sap would rise and transpire more rapidly than the thick, and that, as a consequence, plants provided with the latter would be the better adapted to resist drought. Experiments, however, show that the processes of transpiration are so complex that speculation unchecked by systematic observation or experiment may easily lead the speculator astray.

In practice, therefore, we must inevitably make Nature our mistress and guide. She does not, however, reveal her secrets to the careless and casual observer, but to those who are ready to sit at her feet and patiently learn her processes.

For the present it is possible for us to draw from experience one or two well-established conclusions in relation to the lines along which

---

[*] Previous studies appeared in our issues of April 13 (p. 279), June 15 (p. 446), Vol. LXXXV; July 13 (p. 30), July 20 (p. 50), July 27 (p. 71), August 17 (p. 130) and September 7 (p. 187).

Nature solves the drought problem. We know the value of deep culture and of tap-roots. We have learned that she utilises bacteria for securing supplies of nitrogen and other plant foods, that she regulates the stomata to conserve moisture and prevent excessive transpiration. We have seen that she uses the camel's device for treasuring up stores of liquid in reservoirs underground, in the stem or in the fruit, and what has already been learned, while it reveals our ignorance, nevertheless points the way for further research; and each new discovery makes yet further progress possible. *Hilderic Friend.*

MESEMBRYANTHEMUM.

(*Continued from p.* 34.)

MITROPHYLLUM, Schwant.

Shrublets or rarely stemless perennials, of remarkable habit. Stems all with distinct internodes, or with internodes only developed on the flowering stems, the vegetative shoots then being without developed internodes, or in two species (of one of which the flower and fruit is unknown) apparently entirely stemless. Leaves opposite, two pairs only produced at each growth annually, and each pair different; the first pair free except at the very base, flat above, rounded or keeled on the back; the second pair united from a third part to nearly all of their length into a conical or rarely cylindrical body, minutely crystalline-papulose, especially at the tips. Flowers solitary or developing into lax cymes when in fruit, terminal, pedicillate, with or without bracts. Calyx sub-equally 5-lobed to its union with the ovary. Petals numerous, free, in 3 or 4 series, linear. Stamens numerous, erect, in a column. Stigmas 5–7, subulate. Ovary inferior, with 5–7 sutural ridges on the flat top, 5–7 celled; placentas on the outer wall. Capsule very shortly and broadly obconic, with 5–7 prominent ridges on the flat top and 5–7 valves and cells; expanding-keels usually diverging from the base, with incurved tips, sometimes sub-parallel, broad and flat, with the inner edge raised, with membranous margins; cells shallow, with or without membranous cell-wings. Seeds ovoid or Pear-shaped.—Schwantes in *Zeitschrift f. Sukkulentenkunde*, 1926, p. 181. Conophyllum, Schwantes, in the same volume, p. 321.

Species several, natives of Little Namaqualand. For the type of the genus see later.

The name is derived from the Greek, *mitra*, a mitre, and *phyllon*, a leaf, in allusion to the shape of the united pairs of leaves.

The plants comprising this genus are among the most remarkable of flowering plants, and very interesting on account of their vegetative peculiarity. When in a state of rest each growth or branch terminates in a conical or rarely cylindric, fleshy body. Within this cone, during the months of rest, a pair of leaves, free almost to the base, is being developed, quite invisibly, at the expense of the tissue of the cone, until finally the substance of the latter is all absorbed, except a thin skin that covers and conceals the leaves inside. When the growing period arrives, these leaves burst the skin, increase in size, and spread widely, and from between them arises another pair of leaves united for part or nearly the whole of their length into a cone or cylinder. This cone is sometimes supported upon an internode of stem and sometimes sessile between the spreading leaves, and when the dry season comes the latter wither and dry up, and the cone persists, to repeat the development above described.

This mode of growth is, of course, only a modification of that of the genus Cheiridopsis, to which Mitrophyllum seems to be in some way allied, for the genus comprises two groups, one in which the vegetative and flowering growths are both alike, are permanent and have distinct internodes, and another group in which the permanent vegetative part of the plant is practically stemless and sessile on the ground, without internodes, but produces tall flowering stems with distinct internodes, which die after fruiting. A vegetative growth of this latter group with its free leaves spreading close to the ground, and the cone of united leaves arising from between them, in habit is so very similar to Cheiridopsis peculiaris in the same condition of growth, that without seeing flowers and fruits most people would probably consider them to belong to the same genus.

This remarkable group is one of those I alluded to in *The Gardeners' Chronicle*, 1925, Vol. LXXVIII, p. 412, as being left under Mesembryanthemum when my key to the genera was constructed, because I had no fruits or adequate material by which to separate them. Schwantes, however, has rightly separated the group and founded the genus Mitrophyllum for its reception at the place above quoted, upon the following structural characters:—Flower solitary, terminal, bractless, sometimes breaking through the body of the cone, with shorter or longer pedicels. Calyx 4–5-lobed. Petals in several series, linear, white or pink. Stamens numerous, spreading. Stigmas 7, subulate, as long as or shorter than the stamens. Capsule 7-celled; cells with cell-covers; placentas parietal, without placental tubercles; expanding-keels diverging upwards, with moderately broad wings. Seeds unknown.

It is not stated from which species these characters were derived nor which is the type of the genus. But in the very same volume, p. 321, he divides Mitrophyllum into two genera, and states that M. mitratum is the type of that genus, which he there defines as follows:—"Pedicel with two short, thick bracteoles at the base. Petals and stamens numerous. Stigmas 5, filiform. Capsule 5-celled, without cell-covers; expanding-keels parallel, not touching one another, with small, marginal wings. Seeds Pear-shaped, slightly papulose."—Now, these characters, stated to be derived from M. mitratum, are so different from those of his original description (quoted above), that it is obvious that both sets of characters could not possibly have been made from the same species, and, therefore, M. mitratum cannot be the type of the genus as originally established. For it is those original characters that must be maintained for the genus, as it is not permissible and is against all rule and precedent to deliberately change the characters of a genus in this way, unless it can be demonstrated that a mistake has been made. But here is no mistake, for the characters of his first description do apply to certain species, and, moreover, we also find that Schwantes actually uses them (at the same place quoted) to found his genus Conophyllum, which must, therefore, rank as a synonym of Mitrophyllum.

With reference to M. mitratum, the only claim to generic distinction is that the cells of its fruit have no cell-wings and the expanding-keels are parallel instead of divergent, for there is no other difference. I regard this as merely a structural variation among species belonging to the same genus, because among the large number of fruits I have examined I find that although fruit-structure is fairly constant and reliable (in conjunction with vegetative characters) for distinguishing genera, yet here and there among species that unquestionably belong to the same genus variations occur in fruit-structure that must be disregarded from a generic point of view; such characters as the presence or absence of placental tubercles, presence or absence or rudimentary development of cell-wings, and the contiguity or separation and divergence of the expanding-keels, are all liable to variation occasionally. Therefore, I regard M. mitratum as not generically distinct from the others enumerated here, but it cannot be accepted as the type of the genus, as the structure of its fruit is stated to be different from that originally assigned to Mitrophyllum. I have only seen fruit of M. grande, which was attached to the plant and exactly conforms with the characters of the fruit as described originally by Schwantes, and as he has not mentioned which of the known species is the type from which the characters of his original description were made, I propose that M. grande be taken as the type of the genus. *N. E. Brown.*

(*To be continued.*)

NURSERY NOTES.

MESSRS. S. BALE AND SON.

Situated at Barnstaple, in the county of Devonshire, amid charming surroundings, the Westacott Nursery has traded under the name of Messrs. S. Bale and Son for a very long period and has been responsible for the supply of trees for afforestation and general planting throughout the western counties and in large quantities to the trade.

The magnificent specimens and woods of Coniferous subjects to be seen in this county, as, for instance, the good examples of Silver Spruce, Douglas Fir, Larch, Pine, etc., in the north Devon district, makes it particularly interesting to follow the methods adopted by nurserymen in the raising of these noble trees from seeds, and their subsequent treatment before they become available for the plantation.

It was formerly the practice to procure seedling plants from outside, and the writer's first experience as a lad in this nursery was the thick bedding of a consignment of young Conifers in rows about one foot apart, but since the war it has been found more economical to raise plants direct from seeds which are sown during spring in short, shallow drills a few inches apart, lightly covered with sifted soil and shaded until the young plants are capable of withstanding exposure. Great care and attention is given during the early stages of growth, and the seedlings are not disturbed for a period of two years, when they are carefully lifted and thickly bedded in rows for a further term of two years, at the expiration of which they are again transplanted, and the finest of the batch may be fit for disposal the following season. It will be readily seen, therefore, the time necessary for the production of young trees, and it is really surprising how they can be procured so cheaply from the nurserymen.

Many thousands of Cupressus macrocarpa are raised at Westacott annually, and the methods differ from the above-mentioned in that they are sown in pans, the seedlings placed in small pots and afforded cold frame treatment, and eventually moved on into larger pots and plunged in the open ground until large enough to be sent out.

There is generally a good demand for young Beech trees and enormous quantities are raised. These, together with Ash, Thorn, etc., are sown in broad drills, the seedlings being lifted and transplanted until of sufficient size for disposal. A good local trade is done in the supply of standard Apple trees, particularly such kinds as Bramley's Seedling, Annie Elizabeth, and many local types of Cider-making qualities.

Of shrubs grown, Escallonia macrantha, E. Ingramii and E. exoniensis, Griselinia littoralis, Fuchsia macrostemma var. Riccartonii and var. gracilis; Abelia rupestris, Cistuses, Cytisuses, Spartium junceum, Berberises, Veronica Andersonii vars. Olearia stellulata and O. macrodonta, Hypericums, etc., are all highly prized for planting in the west. A large area closely planted with Hydrangea hortensis—the soil is favourable to good colouring—is an unforgettable picture of great beauty. *H. G. King, Twickenham.*

FOREIGN CORRESPONDENCE.

CYPRIPEDIUM SPECIOSUM.

Hardy Cypripediums are always admired by plant-lovers, whether they are growing in gardens or in their natural habitats, for they add distinct character to the surroundings.

C. speciosum is one of the handsomest and one of the easiest species of Cypripedium to grow. It is found in woodland, where trees are not densely clad, or in open, sunny places growing here and there among Miscanthus sinensis, an ornamental perennial grass, at the bases of the mountains in middle and northern Japan. The habitats in which it grows abundantly are the dry places, where the soil is a sandy loam with a surface covering of a few inches of decayed leaves; it is not deep rooting. Generally it is found in higher altitudes than C. japonicum and C. debile—3,000 feet above the sea-level. The latter two, which prefer shady, moist places, are found mostly at 1,500 to 2,000 feet above the sea-level, but they are often found in lower altitudes. Ten or so years ago, I found C. debile in an old castle, which is only about one hundred feet above sea-level, and about a mile from the sea coast.

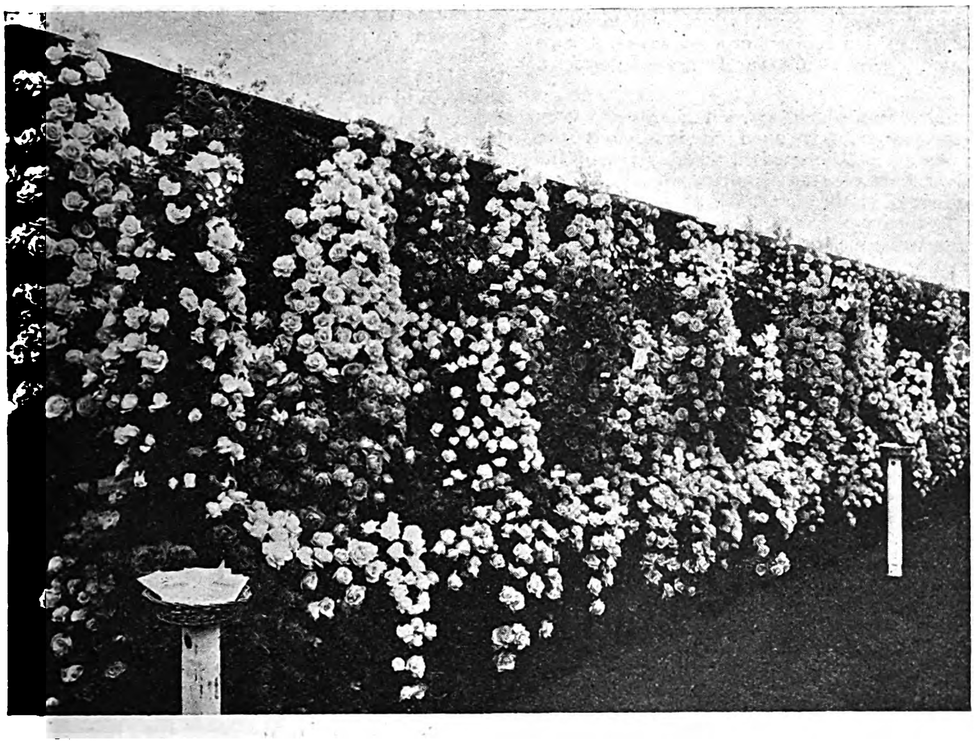

FIG. 103.—SOUTHPORT SHOW: GROUPS OF ROSES.
(see p. 192).

The pubescent stem of C. speciosum is about a foot high, clothed with four or five ovate, dark green leaves, and bearing a single flower, the sepals and petals of which are narrowly ovate, pointed towards the tips; the sub-globose lip is large; the colour is whitish or slightly tinted with pink, veined with dark crimson-purple.

It is best grown in a mixture of two-parts loam and one-part leaf-mould, in shade, which is, however, I think, not necessary in England. To have flowers every year, liberal manuring is decidedly necessary when flowering is finished. *K. Yashiroda, Japan.*

GRANT THORBURN.

I WAS interested in the account of Grant Thorburn which appeared in your issue of May 3. I have bills made out by Grant Thorburn and by his son. These are on plain paper, no printing, and in pounds, shillings and pence, which evidently were in common use here at that time. I also have several very interesting letters of Thorburn's in my collection of autographs of prominent horticulturists. These have considerable historical interest.

Thorburn's was the first seed store in New York, and he was a man of many unusual and interesting experiences. Thorburn's sons were interested in the business and carried it on after his retirement. Later, a grandson, J. M. Thorburn, became owner, and finally a Mr. Elphinstone, who married J. M. Thorburn's sister, was admitted as a partner, also a son, Grant, junior, the latter withdrawing a few years later. The business was then conducted under the name of J. M. Thorburn and Co.

F. W. Bruggerhof started with the establishment as a boy of all work in 1849, and was admitted as a partner by purchase when the store was located at 15, John Street, which I well remember, going there as a child with my father. Later, the store was moved to Cortlandt Street, and then to Barclay Street. Mr. Bruggerhof was in charge up to the time of his death, a few years ago. This store was known generally throughout the trade as the place to buy seeds that could not be found elsewhere in this country. After the senior Bruggerhof's death, it was conducted for a short period by his son, and after the son's death it was sold to inexperienced young men, who soon gave it up, selling what was left. There is practically nothing remaining but claims to the name.

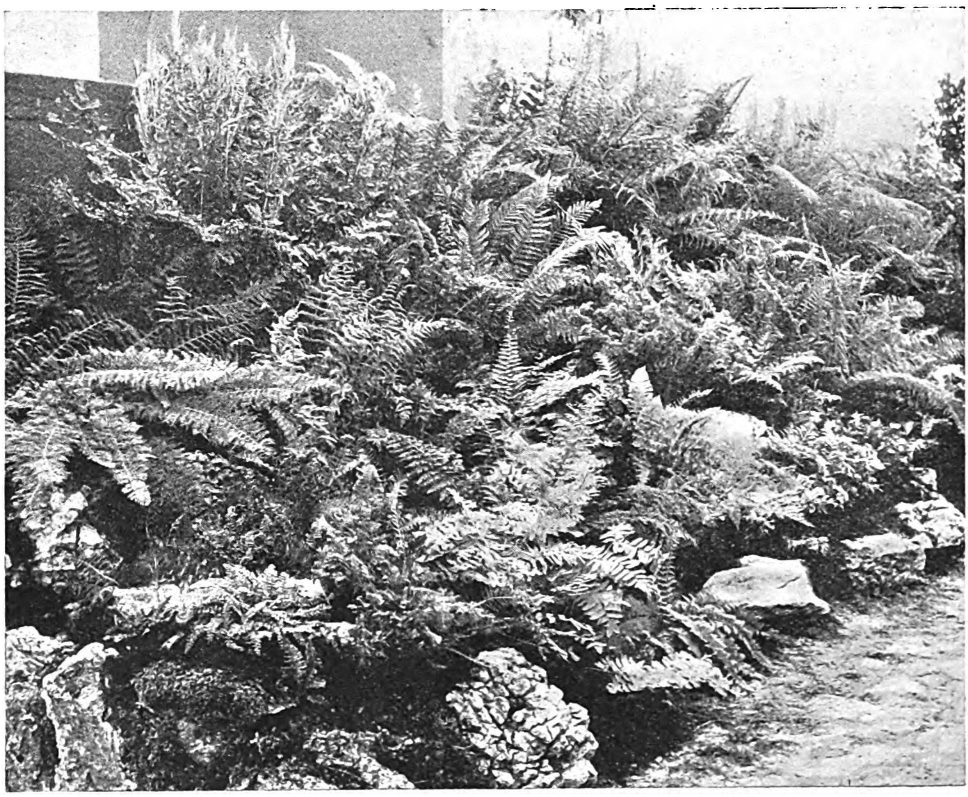

FIG. 104.—SOUTHPORT SHOW: GROUPS OF HARDY BRITISH FERNS.
(see p. 192).

I also have the following Thorburn books:—*The Planters' Guide,* by Sir Henry Stewart, Bart., first American, from the second London and Edinburgh edition, New York, 1832; published by G. Thorburn and Sons. *Laurie Todd,* by John Galt, edited by Grant Thorburn, printed and published by the editor, New York, 1847; autographed by Grant Thorburn, aged seventy-three; this book contains a manuscript by Thorburn: "The first night I slept in New York was the 17th of June, 1794," etc. *Fifty Years' Reminiscences of New York, or Flowers from the Garden of Laurie Todd,* by Grant Thorburn, New York, 1845. *Forty Years' Residence in America, or the Doctrine of a Particular Province Exemplified in the Life of Grant Thorburn, Seedsman, New York, Boston,* 1834; this volume contains the correspondence between Thomas Paine and William Carver, which, in quoting, some of our American writers have decidedly reversed the facts; another volume of the same contains the autograph, "Grant Thorburn, Sr, aged 82 years." *Life and Writing of Grant Thorburn, Prepared by Himself,* New York, 1852. *Laurie Todd's Notes on Virginia; with a Chapter on Puritans, Witches and Friends,* price 12½ cents, New York, 1848. I also have letters of another early British-American horticulturist, William Cobbet. I am now seeking a letter of Linnaeus, having missed an opportunity of purchasing one that was once offered. *E. C. Vick, Newark, N.J., U.S.A.*

ECHINOCYSTIS LOBATA.

ECHINOCYSTIS lobata is a rapid-growing, annual climber occurring plentifully in this locality. Bailey defines its habitat as New Brunswick and Ontario to Montana and Texas. It is most abundant on low, rich ground, especially along brook and river banks, where it sprawls over the ground or clambers over shrubs and stout herbage. The stems and foliage are pale green, each leaf being opposite a three- or four-branched tendril. The leaves are deeply and sharply five-lobed, and are wider than they are long.

The plant is almost glabrous. The staminate flowers, of a greenish-white hue, are borne in showy compound racemes often a foot to fifteen inches in length. One of these racemes rises from every leaf-axil. The fertile flowers are usually solitary, but sometimes occur in small clusters in the leaf-axils. Each is followed by a large, egg-shaped fruit which is at first fleshy but later becomes almost dry and bursts at the summit. The outer side of the fruit is clothed with long, weak prickles. The ovary is two-celled, with two flattish ovules in each compartment.

Echinocystis lobata is a showy subject when in bloom and finds favour as an arbour plant, its rapid growth and attractive appearance making it valuable for this purpose. A synonym is Micrampelis lobata, and the plant is popularly known as the Wild Balsam Apple or Wild Cucumber. *T. H. Everett, New York, U.S.A.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

(*Continued from p.* 190.)

WARWICKSHIRE.—The best crops this season are of small fruits; Raspberries, Gooseberries and Currants have been abundant, with a record crop of Black Currants. Cherries were also quite good. Strawberries were very unsatisfactory owing to the long drought and cold nights, many of the early flowers were spoilt by frost. Apples are well under the average, the best crops being of Worcester Pearmain and Lane's Prince Albert. Pears are not plentiful, and many varieties have failed to crop; this also applies to Plums. *H. F. Smale, Warwick Castle Gardens, Warwick.*

ENGLAND, S.

BERKSHIRE.—Early spring gave promise of a good fruit season, especially of Apples and Pears. Trees of both these fruits carried an enormous quantity of flowers; Pears, whose blossoms seemed very weak, set well, and are carrying good crops, except Doyenné du Comice, Beurré Diel and Santa Claus. Apples set very badly and only on a very few trees is there any quantity of fruits. The following are good, both in crop and quality:—Keswick Codlin, King of the Pippins, James Grieve and Langley Pippin. Cox's Orange Pippin trees are practically barren, likewise Ellison's Orange. Strawberries were the best crop here for years, The Duke being especially good. Cherries were excellent, and so were Gooseberries, Red and Black Currants and Raspberries. *Stanley R. Gammon, Farley Court Gardens, Farley Hill, Reading.*

—— Fruit crops here are average ones. Apples on standards are poor, except Newton Wonder; bush and espalier trained trees are carrying good crops as they escaped the cold winds. Two bush trees of Apple Bountiful have given crops annually for the past twenty years; this variety makes a splendid bush and the fruits keep well. Pears are a good crop of clean fruits and Strawberries were abundant. All bush fruits were good. Fruit trees in general are clean and making good growth. *A. B. Wadds, Englefield Gardens, Reading.*

—— Owing to the severe winter and the late spring frosts—when most of the fruits were in bloom—followed by the long drought, the fruit crops in general are far below the average. *Thomas Wilson, The Castle Gardens, Wallingford.*

—— The hardy fruit yields in this district are very irregular, especially of Apples and Pears. The wood was well-ripened last year, and the severe weather of late winter and early spring, which retarded the flowering period, gave rise to the promise of abundant crops. The sharp frosts registered at night during the spring, dispelled the expectation of an average yield throughout the various hardy fruit crops. Among the varieties of Apples, the Codlin group bears an average crop; the same applies to Lord Derby and Lane's Prince Albert, Wyken Pippin, Allington Pippin and other sorts, which are sometimes regarded as second-rate varieties in prolific cropping years, but are welcome when first-rate Apples, such as Blenheim Pippin, Bramley's Seedling and Cox's Orange Pippin are fruitless. Pears are variable; Louise Bonne of Jersey, Doyenné du Comice and Pitmaston Duchess are barren. Bush fruits fruited well, especially Black Currants. Strawberries were plentiful, but their season was shortened by the prevailing heat, although the plants did not appear distressed through lack of root moisture on our soil, which is Bagshot sand with outcrops of loam. *Frederick Gooch, Earlywood Gardens, Ascot.*

DORSETSHIRE.—The garden here is very scattered, some of it on high land, but the older portion of the garden, where most of the fruit has been planted, is situated in a valley, at the foot of chalk hills. We do not, as a rule, suffer badly from drought, but are very subject to severe winter and late spring frosts. Apples flowered well, but we have good crops of Beauty of Bath and Early Victoria only. Other varieties are very thin or barren. Pears are quite good and look well. Cherries were very good, but black fly has proved troublesome. Plums gave a really good show of blossom, but fan-trained trees on a north wall are the only trees carrying good crops. Many standards are barren. Peaches, both outdoors and under glass, are very satisfactory. Strawberries were an average crop, but the fruits were of excellent quality. Black Currants and Gooseberries bore heavy crops and look well. I was agreeably surprised with our Gooseberry crop. Last year, in spite of two sprayings with ammonium polysulphide, we suffered rather badly from mildew, so much so that I destroyed half the plantation. The remainder, on the principle that very little harm could be done, if no good, were sprayed thoroughly with tar-distillate, as late in the season as I dared. The bushes have not been sprayed with ammonium polysulphide this season, but they are free from mildew. Perhaps someone will tell me why this should be so. I should have mentioned that all the bushes were tipped thoroughly during early winter. Loganberries were cut almost to the ground here by the severe winter frosts. Lloyd George Raspberry was also badly cut, but the surviving canes of this variety are carrying a good crop. *Henry F. Maidment, N.D.H., Crichel Estate Gardens, Wimborne.*

—— In this district Apples are a very light crop, except a few early varieties. Cox's Orange Pippin did not flower, but this was not because the trees carried a heavy crop last year. Loganberries were killed back to about a yard from the ground, and Figs suffered severely from frost. Fruit trees generally are clean although red spider is very prevalent. The rainfall for the year up to the end of June was 7·53 inches, the lowest fall I have recorded, and about half the average.—*W. E. Axford, St. Giles Gardens, Salisbury.*

(*To be continued.*)

FRUIT GARDEN.

TWO GOOD OUTDOOR PEACHES.

THE list of varieties of Peach given by Mr. H. H. Cook on p. 124 (Vol. LXXXVI) is excellent and calls to mind two other sorts that have been and are doing well on a south wall outside. While in Worcestershire, Dr. Hogg did remarkably well; it is a finely-coloured Peach, ripening in August; the tree is hardy and a good grower. The flesh is firm, and sometimes has a red appearance and always a sweet flavour. It generally cropped well, and the fruits came a medium size—quite a desirable outdoor variety.

Duke of York does remarkably well here in Buckinghamshire. Last year, a large tree on a south wall ripened its fruits in July—at the same time as a tree of the same variety ripened its fruits in a cool house. Although the outdoor fruits were not so large in size, yet the crop was—and is this year—a heavy one, and the flavour quite good. On our gravelly soil growth is not as robust as one could wish. The tree needs plenty of feeding to balance its heavy cropping. It is well-coloured and of a good flavour, also very reliable. *G. H. Emmett, The Gardens, Taplow Court, Taplow, Bucks.*

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Linums in semi-shade.—In his note on Linum viscosum, on p. 151 of your issue for August 24, your contributor *North Wales* mentions that the plant has flowered under conditions of partial shade, and my experience with another of the Flaxes, namely Linum grandiflorum var. rubrum, leads me to think that the general rule of selecting a very sunny spot for Linums can be too strictly adhered to. From seeds sown early in May there is flowering outside my window a batch of Linum grandiflorum var. rubrum on which flowers have been produced in a seemingly uninterrupted sequence since the first week in July, and there seems the promise of a display for a week or two yet; this on a plot of ground on which the sun never shines before three o'clock in the afternoon. I have noticed batches of the same plants in hot, sunny situations this summer and it seems they were exhausted some three weeks ago. Furthermore, I have recollections of seeing, a year or two back, L. monogynum and L. narbonense flowering profusely on a shaded part of the rock garden at Kew. *W. Howell, 44, Riverside, Abbey Estate, Cambridge.*

National Carnation and Picotee Society.—For the information of your readers, and in order to clear up the doubt at present existing in the minds of prospective members, and thus avoid further confusion, I think it necessary to intimate that there is only one National Carnation and Picotee Society (of which I am the Hon. Secretary), and that it has no sections. There is a Northern Carnation Society with headquarters at Sheffield, which is often wrongly reported and referred to as the N.C.P.S. Northern Section, but that body has no connection with the N.C.P.S. other than that of an ordinary affiliated society. I understand many persons are under the impression that by joining the Northern Carnation Society they become members of the N.C.P.S., and are therefore entitled to the various benefits offered by that Society, but this is not so. Membership forms and subscriptions intended for the National Carnation and Picotee Society should be sent to me, at 10, Bergholt Road, Colchester, or to the Hon. Assistant Secretary, Miss J. B. Wells, Fairlawn, Jeffrey's Road, Clapham, S.W. *A. E. Amos.*

Gardening Fallacies.—The two points in Mr. Callwell's note (p. 154), in which I am especially interested, deal with efficient tools used for many different purposes in a garden, and the age of men expected to use them. There should be no difficulty in these advanced days of science and machinery to obtain efficient and useful tools. A catalogue of these is easily obtainable from horticultural firms who advertise in *The Gardeners' Chronicle*. Their agents or representatives are ever ready to give expert advice, and demonstrate, free of charge, with special tools. In many cases it is not altogether the tool employed that is at fault, but the way it is used and cared for. It should be particularly noted that care of tools is often neglected. Even in times of drought, a little water is available in which they may be washed, and if this is followed by a coating of oil, the life-time of many tools is prolonged, and they will remain in good working condition. Tools of medium size, as example No. 1 spades and forks; a six-inch and four-inch Dutch hoe to form a pair, will be found most suitable. Many men at fifty and sixty years of age can be employed with satisfaction and reliability, and prove equal to one of twenty. I think fifteen to twenty years is not too long a period to be trained in flower, fruit and vegetable culture. Many of our best men are not young gardeners. Taking into consideration the great problem of unemployment among men at the moment, it is only fair to suggest that preference should be given to those men rather than to women, although, perhaps, the services of the latter in gardens may be unsurpassed in certain directions. *Chas. Stapler, Mottingham, Kent.*

SOCIETIES.

DUNDEE HORTICULTURAL.

AUGUST 29, 30 AND 31.—Seldom, if ever, has a finer display been made under the auspices of the Dundee Horticultural Society—now over a century old—than that staged on these dates on the Magdalen Green, Dundee. The entries last year—1,660—were thought to be a record, but this year they totalled 1,860, and comprised in them were admirable examples of the skill and intelligence of Scottish gardeners. The Marchioness of Linlithgow gave the proceedings a happy send-off, and Mr. James M. Martin, the Hon. Secretary, attended to details, while Mr. Alex. Duncan, The Gardens, Duncarse, ably managed the exhibition.

Pot plants have always made one of the best features at this show, and there was no exception on this occasion. Keen competition marked the section, and the judges found no little difficulty in making their awards. Outstanding were the remarkably fine specimens of greenhouse Ferns and Palms, the latter commanding warm admiration. From Invertay Gardens, West Ferry (gr. Mr. George Reid) came a wonderfully fine display. Mr. Reid led for four plants distinct; four exotic Ferns, Pelargoniums, single and double; specimen plant in flower, four British Ferns, distinct; one Tree Fern; a collection of twelve pots of alpines, distinct; four exotic Ferns; and six table plants.

Hazelwood Gardens (gr. Mr. W. D. Grieve), were also well represented, and had premier honours for Begonias, double, in flower; three fine foliage plants; one pot of Liliums; one specimen plant, in foliage; and for Palms. H. HOGARTH, Esq. (gr. Mr. W. Hunter), Delvine, Murthly, showed the finest early-flowering Chrysanthemums; ARCHIBALD RETTIE, Esq. (gr. Mr. J. Margach), Seafield Lodge had the best early-flowering Chrysanthemums, not disbudded; DOUGLAS NAIRN, Esq. (gr. Mr. James Smart), Elmslea, earned warm praise for his finely-grown Lilium auratum; and GEORGE BONAR, Esq. (gr. Mr. Martin Taylor), The Bughties, Broughty Ferry, had fine wins for his Coleuses and Cycas. Rarely have better examples of Coleuses been shown at Dundee.

Cut flowers were an excellent display and reflected the highest credit on all concerned. The Sweet Peas and herbaceous exhibits were noteworthy. The judges had a stiff task in awarding the Corporation Cup for the best exhibit in the section, but the finely-grown flowers sent in from Binrock Gardens, Dundee (gr. Mr. J. Beats), could not be passed over. From the same gardens came the best annuals (hardy and half-hardy), Chrysanthemums and hardy border flowers.

Roses formed a fine feature, and here JOSEPH HARPER, Esq. (gr. Mr. A. Armit), Rathillet, Cupar gained a well-earned victory in the class for twenty-four Roses, H.P. or H.T., distinct, with a notable entry of Hybrid Teas. In the corresponding class for twelve Roses, any one variety, the honours went to Mr. F. WHEELER, Alice Bank, Tayport. The Gladioli and Dahlias from Delvine Gardens were worthy of their awards. Some fine displays were shown among the decorative classes, a prominent winner being Mr. D. BEATS, gardener at Taybank, who scored fine successes for hand bouquets and baskets of Roses. From Balnacraig, West Ferry (gr. Mr. Peter Kerr), came the best wreaths of flowers and bowl of Sweet Peas. Dahlias and border Carnations were finely shown from East Newport (gr. Mr. R. Fernie), but the chief tussle in the cut flowers section was among the Sweet Peas, when those two doughty growers, Mr. J. MACINTOSH, Cornhill, Aberdeen, and Mr. J. B. CAMPBELL, Newport, came face to face. The most meticulous care had to be exercised by the judges in making their awards for the best sixteen vases of Sweet Peas, not fewer than twelve varieties. In the end, however, the Aberdeen man won, and the Macdonald Trophy was placed in his keeping. No doubt the contest was very close, but the best won. These two expert growers have had numerous successes this season. Mr. MACINTOSH gained outright the Silver Cup for Sweet Peas at Elgin, performed a similar feat at Forfar, although not outright, and now comes his Dundee success. Mr. CAMPBELL has also had some fine victories during the season.

Both in regard to entries and the quality of the exhibits, the fruit section was well up to standard, but there have been bigger entries at Dundee. There was a fine show of Grapes, and although better colour might have been seen among the Muscats, it was a meritorious display.

S. H. SHARP, Esq. (gr. Mr. W. M. Willocks), Balruddery House, had the best three varieties, best Black Hamburgh, and the best for bloom. Colonel TYRIE (gr. Mr. Thomas Dobbin), St. Helens, Dundee, also showed winning entries of Black Hamburgh and Lady Downes. From Kinfauns Castle Gardens (gr. Mr. R. Astley), came the best specimens of Muscat of Alexandria Grapes and purple Plums.

H. LYALL, Esq. (gr. Mr. R. Duncan), Old Montrose, was a noted winner in this section, scoring successes for the best collection of hardy fruits, dessert and culinary Apples, Pears, and red Plums. LORD KINNAIRD (gr. Mr. J. Macgregor), Rossie Priory, sent the winning Peaches, Nectarines, yellow Plums, Victoria Plums, dessert Pears, and the best collection of hardy fruits grown in the open. While the classes for Apples were not quite so well filled as they have been at Dundee on previous occasions, they were, all over, and considering the weird season we have had, wonderfully good. The finest came from the gardens of Old Montrose, Rossie Priory, Inchture, Pinegrove, Benvie, The Bughties and Rathcluan. Small fruits were finely represented; Currants, Gooseberries and Raspberries showed commendable quality and earned much admiration.

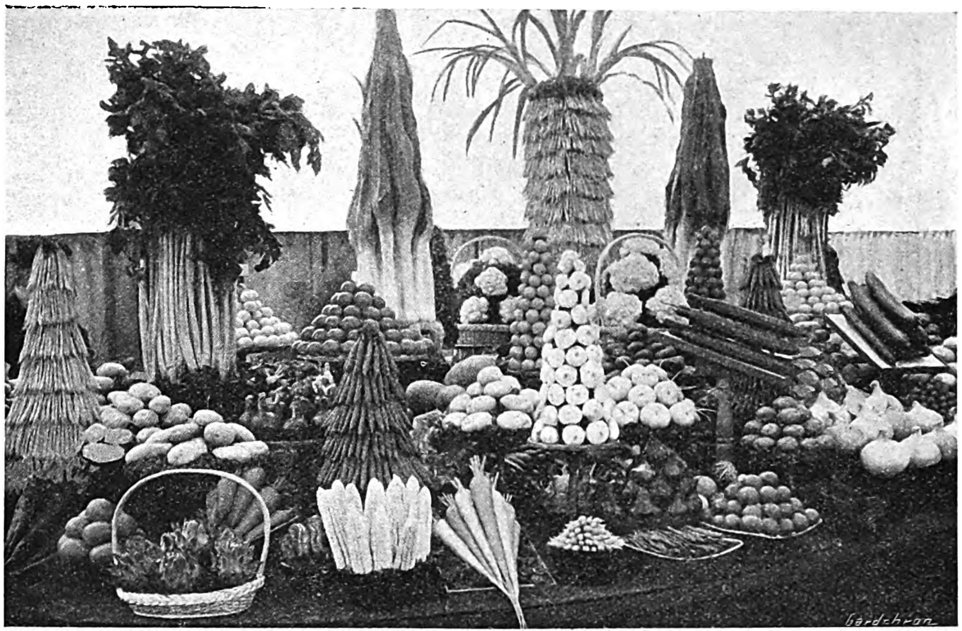

FIG. 105.—SOUTHPORT SHOW: LORD LECONFIELD'S FIRST PRIZE EXHIBIT OF VEGETABLES. (see p. 193).

The vegetable section is always a strong one at Dundee, and, as of yore, a high standard of quality was reached. Carrots, Onions and Turnips were specially fine for size, quality and formation.

The leading struggle was for the best collection of vegetables, twelve kinds, distinct, on a side table, space not exceeding seven feet by four feet. A very close contest took place here between D. H. W. RITCHIE, Esq. (gr. Mr. D. Pullar), Dura, Cupar, and H. HOGARTH, Esq. (gr. Mr. W. Hunter), Delvine, but the Dura collection triumphed. It required experts, however, to mark the distinctions, only one point separating the contestants.

Outstanding entries came from Rathcluan Gardens (gr. Mr. David Dalrymple). These took leading places for Tomatos, Onions (red), Beetroots, Kidney Beans, Potatos and Turnips, Lismore Gardens (gr. Mr. Joseph Dick), led for the best collection of vegetables, six varieties, and for Leeks and Cucumbers. The latter were greatly and deservedly admired. The Cauliflowers from Delvine Gardens were a prominent feature, as also were Peas, Carrots and Parsley from the same source. As one of the judges remarked, there have never been seen at Dundee finer specimens of Cauliflowers than on this occasion. There were samples on view unplaced that were worthy of first places at leading exhibitions, and well-merited praise was awarded the growers.

As might be expected, remarkably fine work was shown by the nurserymen and florists. Many of the fine entries of Roses were simply unimpeachable. Messrs. D. AND W. CROLL, Dundee's famous Rose growers, had matters pretty much their own way in all the classes, with Messrs. CHARLES ARNOT AND SON, Rosebank Nurseries, Forfar, making good seconds.

It is to be feared the judge is not yet born who could accurately discriminate between whether many of the exhibits shown by the amateurs were grown by professionals or amateurs. Very high skill was evidenced in all the amateur's classes and this redounded to the credit of all concerned. The blue ribbon in the amateur section, the Corporation Challenge Cup, was awarded to the best exhibit in the vegetable classes, nine kinds. Mr. ALFRED DRUMMOND, Wester-Fowlis, Crieff, secured the award with 31 points, the runner-up being Mr. A. THOMSON, Blairgowrie, who secured 27½ points. Mr. RICHARD MOORE, Cleghorn Street, Dundee, gained the Cox Challenge Cup for the best exhibit in the pot plant section with four finely-grown foliage and flowering plants. Mr. J. PEARSON, Castle Terrace, Tayport, and Mr. J. G. HENDERSON, Taybank, Newburgh, were prominent for fruits, and Mr. R. FERNIE, East Newport, and Mr. J. S. MARTIN, Milnbank Road, Dundee, were the chief leaders for cut flowers. Mr. DAVID SMITH, Lochee, Dundee, gained the Silver Medal presented by *The Gardeners' Chronicle* for the best amateur's exhibit in the cut flower section, with a remarkably fine group.

The children's wild flower exhibits comprised one of the most successful items of the show, the little ones, all under fourteen, coming forward in large numbers with their posies of wild flowers and grasses; and they made a brave show. FLORA FORSYTH gained first place for the best collection of wild flowers and grasses, while JOAN ELLIS, Grove Academy, had the finest pressed flowers.

Non-competitive displays were shorn a little bit by the absence of southern firms, who invariably put up superb displays at Dundee. No doubt owing to the exhibition clashing with the great Southport event, these firms had determined to limit their displays to that quarter. An exception was made by Messrs. Allwood Brothers, Haywards Heath, which was the only southern firm to make a display. The local nurserymen and florists, however, rose finely to the occasion, and staged some of the finest products ever seen at Dundee. Space will not permit of a detailed description, suffice to state the displays made by Messrs. D. and W. Croll, Messrs. Storrie and Storrie. Messrs. G. and A. Stobie, Messrs. Laird and Sinclair, Messrs. Thyne and Son and Messrs. W. and E. Dryden, were all worthy of the fine traditions of these highly esteemed firms, and added materially to the success of the 1929 Dundee Floral Carnival.

GUILDFORD GARDENERS'.

In continuation of the summer programme of visits to gardens, a small party of members of this Association visited Derry's Wood, near Wonersh.

This is a comparatively new place as gardens go, the house being built by Mr. J. M. Courage in 1903. It is in a situation of delightful seclusion and sheltered on the north by a forest of Fir trees that crown the ridge running from Wonersh right along to Leith Hill. Mr. Joy, of Snowdenham, the former home of Mr. Courage, took a hand in the first lay-out of these grounds, and planted some of the earlier trees. This work was continued by Mr. Elliott, who became head gardener about twenty-three years ago, and still occupies that position. The place has developed under his guiding hand.

There is a great deal of natural beauty in the situation and surroundings. A considerable space is given up to formal gardens, and Yew hedges, clipped in divers shapes, add to their attractiveness, while costly urns containing Fuchsias are dotted here and there. Lawns and borders of annuals and herbaceous plants are all neatly kept and plentifully stocked, as in the large section devoted to Roses. One striking feature was a row of over twenty Red-Twig Limes, the branches of which are trained to meet from one tree to another, as compact as a green wall, with arches that afford delightful shade or shelter.

In the drive, and in fact, all round, are very many rare trees, Japanese Maples, American Red Oak, Cupressus Lawsoniana var. aurea, and Cedars. It is evident that money has been freely spent to create and maintain so charming a place.

In the kitchen garden things were looking remarkably well, and Mr. Elliott said he had grown the best crop of Strawberries he had seen since the dry summer of 1921, when Strawberry trouble began.

In the immediate neighbourhood is the smaller garden of Mr. G. L. Cruddas, at Upper Lostiford, to which a visit was paid. At this place the gardener, Mr. Parkhurst, excels in Carnations, but to the visitors the glory of these gardens was its two double borders, arranged to cross each other at right angles—or it might be called four double borders that meet in the centre. Each wing was filled with summer flowers—dwarf varieties in the front and taller subjects one behind the other. Violas, apricot Nemesias, Phlox Drumondii, Stocks and many other kinds were all in flower, and by common consent were voted to be among the very best to be seen in any garden, small or large.

This outing was too near Bank Holiday, as was shown by the reduced numbers attending, but was very enjoyable to the few who participated.

By permission of Lord Leconfield, a repeat visit was made to Petworth Park, on Saturday, August 17, by members of this Association. A large party availed themselves of the opportunity. The Park itself is enclosed in a wall ten or twelve miles long. The mansion is immense and imposing, a veritable treasure house, and is open to the public on Tuesdays and Thursdays every week from 11 a.m. to 2 p.m.

The gardens, in every section, are the gardens of the specialist, the products being notable alike for variety and excellence, under the guiding hand of Mr. Streeter, assisted by a competent foreman in the person of Mr. Berry, and a staff of about thirty under-gardeners.

Crossing the Park on the way to the garden, a very large Tulip Tree may be seen. This is one of the original five trees of this kind first introduced into England. It is verging towards decay, but even so it bore a tremendous quantity of flowers this year, the ripening seed-pods of which are on the tree. Another still more striking instance of fertility in an advanced stage of decay was seen in an old Medlar tree. This is so far gone that support alone prevents it trailing on the ground. Practically nothing but the outer shell remains, but in it flows the life-giving sap, so that this old relic, stated to date back to the days of Charles I, whose children played beneath its shade, is bearing its usual heavy crop of fruits to-day. Rare trees, old and new are here.

In the gardens everything seems on the same scale. Herbaceous borders run to just a mile, varying from fifteen feet to twenty-five feet in width. One section of this is the experimental site of six hundred new seedling Phloxes. Mr. Streeter is aiming at a plant that will be larger in the truss of flower, strong enough to stand without staking, and of good colour. This large section was seen at its very best, and red, white, and many shades of pink blooms in very large trusses presented a dazzling appearance.

In another section was a demonstration of what can be done with Antirrhinums when grown well. This was a circular bed, in a grass patch surrounded by borders of the same kind of plant. Here again were many colours and plant battalions—thousands of them all in flower. Around the circular bed was an edging of Alyssum maritimum, and a groundwork of dwarf Heliotropes, with standard Heliotropes waving above the whole; a very effective group.

Among the shrubs one small specimen came in for special notice, because of its berries. This was Coriaria terminalis var. xanthocarpa—the berries were in clusters like a small bunch of Grapes, and amber in colour.

In these gardens eighteen varieties of Capsicum are grown; and in a pool there is a bed of Cranberries.

In the houses were several unusual varieties of Tomatos. Peaches were over, but vast quantities were maturing on outside walls. It must be acknowledged that things grown at Petworth House are on a scale not usually seen.

Other factors added to the pleasure of this outing. First, the ideal summer weather that prevailed, and the richness of the summer verdure on all hands; the August rains had given renewed life, and vegetation had the richness of spring, which made the scenery so

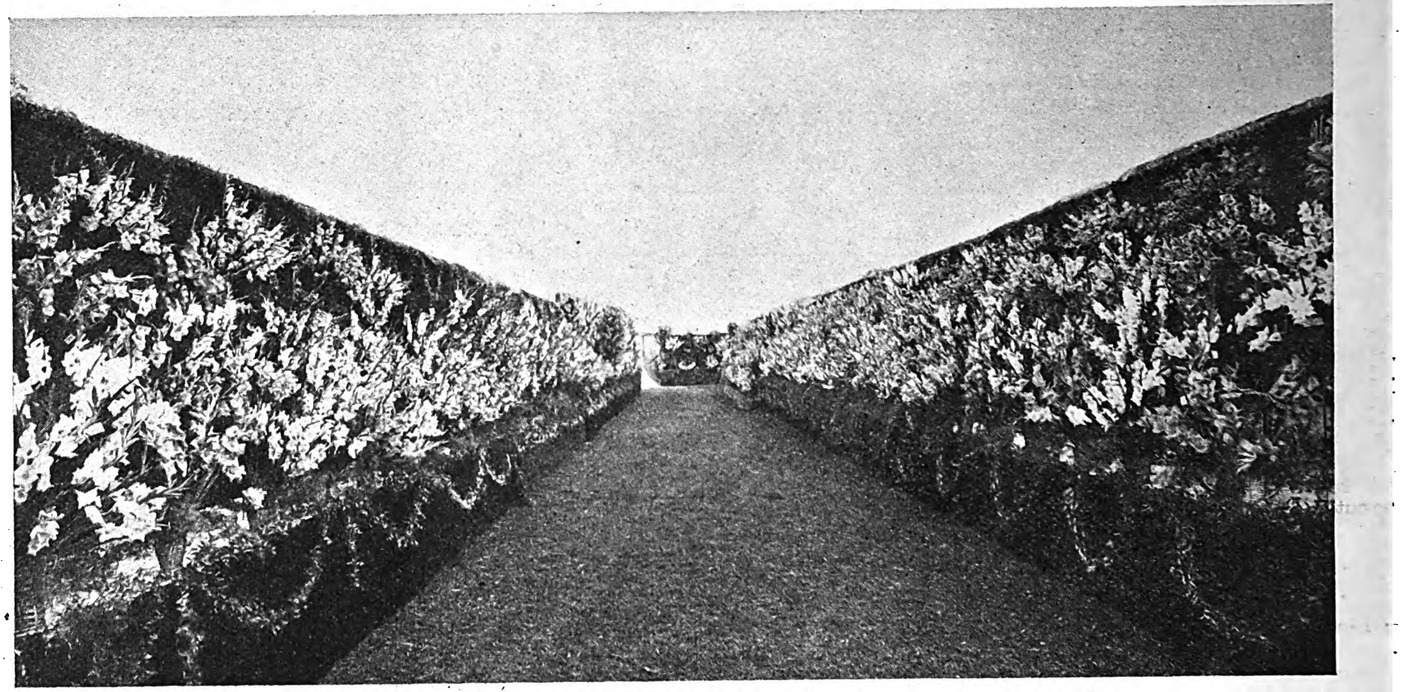

FIG. 106.—SOUTHPORT SHOW: THE "AVENUE" OF GLADIOLI.
(see p. 195).

delightful, especially on the way home, when the road led through Cowdray Park at Midhurst, and again on the hills near Fernhurst which afforded entrancing views across Lurgashall Vale, and away on to the South Downs.

The programme for the season was completed on Saturday, August 31, when a visit was paid to the Royal Gardens, at Frogmore, Windsor, the glories of which cannot, however, be expressed in a paragraph, and must be left to the imagination.

FORFAR HORTICULTURAL.

August 23 and 24.—Forfar, the capital of the ancient and historic province of Angus, and the homeland of the Duchess of York, was *en fete* on these dates, the Reid Hall and its surrounding grounds being the venue of the premier annual horticultural display in the province. There were over 1,100 entries, an increase of fully 400 compared with last year—a record of which the Forfar Horticultural Society has just cause to be proud. Sir Robert Hutchison, M.P., gave the proceedings a happy send-off, and Mr. Andrew B. Caird, the Secretary, made admirable arrangements before and during the show. Mr. James W. Mackintosh, Rosehill, Aberdeen, secured the Silver Challenge Rose Bowl for a superb entry of Sweet Peas. The Silver Cup presented by Lady Hope, Kinnettles, for the most points in the cut flower classes went to Mr. Low, West High Street, Forfar, who also won the Silver Medal for the most points in the show. The Milne Challenge Cup, awarded for the most points in cut flowers and vegetables (confined to amateurs) was gained by Mr. James Brown, Canmore Street, Forfar, with thirty-four points, but the runner-up, Mr. G. Saddler, Forfar, was only one point behind.

The pot plants made a very fine display, and here Mr. Low led for the best table of plants and cut flowers, arranged for effect, with a remarkably good entry. Mr. James Stark, Wardbank, Forfar, led for Begonias, Pelargoniums (single and double), Fuchsias, Coleus and Hydrangeas. Liliums in bloom and Celosias pyramidalis were shown best by Mr. A. Low; Mr. D. Steele, Mid-Langlands, fully earned his victory for Chrysanthemums.

The cut flowers proved very pleasing, and here Mr. A. Low took leading places for Collerette Dahlias, Pompon Dahlias, Stocks, Phloxes, annuals grown in the open, and herbaceous flowers. Mr. D. Steele took premier places for Asters, Pentstemons, Dahlias and wreaths. Other prominent names in the professional classes included Mr. Roy McGregor, Mr. William McGregor and Mr. James Brown, Canmore Street.

Some very good entries were forwarded in the fruit classes. Mr. William McGregor had fine wins for the best collection of fruits, Grapes (white), Apples (culinary), and Red Currants. Mr. W. Forest, Logie, had the best collection of hardy fruits grown in the open, Plums, and Pears. Mr. G. Hendry had easy firsts for Melons, Peaches, Plums, Apples (dessert), Pears and Gooseberries. Mr. Jack Milne led for Grapes (black), Strawberries, Black Currants and Cherries, while Mr. James Stark had the best Black Grapes — for bloom.

Vegetables, as has been the case generally this season, were well shown, and Mr. George Hendry, Carsegrey, was a prominent winner. He had the best collection of vegetables (nine varieties), Onions, Cauliflowers, Cucumbers, Broad Beans, Leeks, Celery (white and red), and Potatos. Mr. A. Low secured premier honours for Potatos, Beet, Vegetable Marrows and Turnips. Other prominent winners here were Mr. P. Lawson, Lunanhead; Mr. G. T. Hardie, and Mr. William McGregor. The most points among professional gardeners were gained by Mr. James Stark (pot plants), 33 points; Mr. A. Low (cut flowers), 71 points; Mr. George Hendry (fruit), 22 points, and (vegetables), 41 points.

Diplomas were granted to Mr. James Mackintosh, Aberdeen, for the best eight vases of Sweet Peas; to Messrs. Bruce and Robbie, Forfar; to Mr. James S. Mackay, Dundee Road, Forfar, for Chrysanthemums; and to Mr. James Brown, for Turnips.

NORTHAMPTON FLORAL FÊTE.

The above Flower Show and Fête was held early in August, in Abingdon Park, and proved a success in every way. Over 25,000 people visited the show.

Competition in the groups of Roses was especially keen. The Dover Challenge Cup was won by The Dowty Roseries, Wokingham, Mr. G. Burch, Peterborough, being placed second, and Mr. H. Drew, Longworth, third.

The Astbury Challenge Cup for Sweet Peas was won by Messrs. E. W. King and Co., Coggeshall, Messrs. H. E. and W. Lach, of Willingborough, being placed second. Messrs. C. Engelmann, Ltd., were awarded the Sears Challenge Cup for a very fine exhibit of Carnations, while for a collection of hardy herbaceous cut flowers, the Panther Cup was awarded to Messrs. Harkness and Sons, Leeming Bar; Messrs. Thomas Perkins and Son, Northampton, were second. Messrs. Sutton and Sons secured the Edward Lewis' Challenge Cup for the best non-competitive display in the show.

Large Gold Medals were awarded to Messrs. John Perkins and Son and Messrs. Thomas Perkins and Sons, both of Northampton, for special collections of plants and shrubs. A Gold Medal was awarded to Messrs. Rambotham, Bletchley, for a group of Roses; and Silver Medals to Mr. John Golding, Fordham, for Scabious and to Councillor E. Ingman, Northampton, for a miscellaneous collection of cut flowers. Mr. T. Burrows, Kingsthorpe, received a Silver Medal for Fuchsias and Ferns; and Messrs. Yarde and Co., Northampton, a Silver-gilt Medal for floral designs. Mrs. Thomson, Braunston, Rugby, was awarded a Silver Medal for a fine collection of vegetables.

For a group of flowering and foliage plants, Messrs. Cypher and Sons, Cheltenham, were first, and Messrs. H. E. and W. Lach, second; and in the class for a collection of tuberous-rooted Begonias, the first-prize was awarded to Sir James Crockett (gr. Mr. W. Meakins), Dallington; second, Berrywood Mental Hospitals (gr. Mr. A. W. Wright). Mr. H. Drew was first for thirty-six Roses; Mr. G. Burch, for eighteen Roses; The Dowty Roseries for twelve Roses; and Mr. H. Drew, for a basket of Roses.

For twelve vases of Sweet Peas, Mr. B. Simcoe, Wollaston, was placed first, while Mr. H. Ellison, Finedon, led for six vases of Sweet Peas.

The first prize, together with the Medal presented by *The Gardeners' Chronicle*, for the best twelve bunches of hardy herbaceous flowers, were awarded to Mr. G. Adams, Kettering. Miss G. Burt, Coggeshall, was first for a table decorated with Sweet Peas. Mr. F. Bostock led for one decorated with Carnations; while for a dinner table decorated with any kind of flowers, Mrs. King, Kempton, received the premier award.

In the fruit section, Mrs. D. C. Guthrie staged the best collection; Mr. G. H. Winterbottom led for black Grapes; and Mr. F. Bostock for white Grapes and Peaches.

Mr. G. H. Winterbottom was first for dessert Plums; Mrs. Borwich (gr. A. G. Moore), for Melons; Sir James Crochett, for dessert Apples; Mrs. Borwick, for culinary Apples; Sir James Crochett, for Gooseberries; Mr. F. Bostock for Black Currants; the Dowager Lady Annaley, for Red Currants; and Sir James Crochett, for Raspberries.

In the open class for a collection of vegetables, for the T. Wall Challenge Cup, there was keen competition, the trophy being secured by Mr. C. Kitchener; second, Mr. G. H. Winterbottom.

The Dowager Lady Annaley led for Tomatos; Sir James Crochett for Potatos; Mr. G. H. Winterbottom, for Onions; Mr. A. Moore, for Peas; Sir Hereward Wake, for Runner Beans; Mr. C. Kitchener, for long Carrots; and Mr. G. H. Winterbottom, for Cauliflowers.

In the amateur classes, Mr. C. S. Duffield took many prizes for Roses and Sweet Peas, including the Tompkins Silver Challenge Cup; Mr. C. Kitchener was very successful in the vegetable classes.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

The three days' show promoted by the above Society in conjunction with the Corporation of Glasgow, was opened in the Kelvin Hall, on Tuesday, September 3, by Lady Inverclyde. There were 467 classes, and the entries numbered 3,980, an increase of 1,500 compared with last year's total.

Flowers.

Pot plants and cut flowers provided a fine display, and except in a few solitary classes, the standard of culture was quite up to the average, despite the unfavourable season in Scotland.

In the class for a group of stove and greenhouse plants arranged for effect on the floor, and occupying a circle twenty feet in diameter, W. G. McBeth, Esq. (gr. Mr. R. White), Dunira, Comrie, won the City of Glasgow Challenge Cup, defeating Mr. W. Smith, Dunecht, and Mr. T. M Petch, Great Horton, Bradford. Mr. John Rae, Biggar, staged the best collection of Begonias, and Sir John Reid (gr. Mr. John Davidson), Ardencraig, Rothesay, was successful in the classes for pot plants, viz., specimen Palm, three Palms, six Nephrolepsis, three Dracaenas, six dwarf table Ferns, six British Ferns and three Kochias. Sir Hugh Reid (gr. Mr. Allan Dunbar), Belmont, Springburn, excelled with six plants for table decoration, three Codiaeums, and in both classes for Liliums.

Roses were of varied quality. Messrs. D. and W. Croll, Dundee, defeated Mr. Thomas Robinson, Nottingham, and Mr. R. C. Ferguson, Dumfriesshire, with a collection of cut blooms, but the last-named competitor excelled in the classes for six baskets of twenty-four blooms; 12 blooms, yellow (Golden Emblem); and twelve blooms, red (George Dickson). Messrs. Adam and Craigmyle, Aberdeen, scored in the class for forty-eight Roses. This was, perhaps, the most even exhibit in the Rose section, and contained clean, well-formed blooms of Captain Kilbee Stewart, Margaret McGredy, Constance Casson, Villa Pia, Edel, Mrs. Barraclough and J. G. Glassford. The Aberdeen firm was also first in the class for twelve varieties introduced since 1926, while their boards of Mrs. Henry Bowles, Madame Louise Crette and Admiration were first in the pink, white, and any other coloured Rose classes. The best cream Roses (Miss Wilmott) were staged by Mr. William Ferguson, Dunfermline.

Mr. J. A. Grigor, Banff, was the most successful exhibitor in the Sweet Pea section, he having been placed first in the classes for twenty-four vases, twelve vases, nine vases and a single vase competition for crimson, pink, cream, orange-pink, orange-scarlet, blue and purple. In the remaining seven classes for single vases of one variety, Mr. John Loan, Coldstream, secured leading awards.

For a collection and for twelve vases of perpetual-flowering Carnations, Messrs. E. Engelmann, Ltd., had no opposition, while Messrs. Torrance and Hopkins, Busby, had a similar experience with their exhibit of border Carnations and Picotees. Other prize-winners in this section were: Mr. Alex. McMillan, Cumnock (six vases Carnations), and Mr. James Smith, Darvel (three vases).

Dahlias were shown in splendid condition, and the competition was notable for the success of Messrs. Torrance and Hopkins, Busby, who were awarded chief honours for their collection, six vases decorative, six vases miniature and six vases Cactus Dahlias, but they were defeated by Mr. Claud Jenkins, Cambuslang, in the class for twelve vases Pompon Dahlias. They found compensation, however, in winning first prize for twelve vases of early Chrysanthemums in open competition. Mr. J. W. Forsyth, Luton, had the best collection of Chrysanthemums, thereby defeating all the local growers.

A double success by Robert Dunlop, Esq. (gr. Mr. James Currie), Barskimming, Mauchline, was recorded in the open herbaceous classes for twelve and six vases, and Messrs. George Mair and Son, Prestwick, excelled with Gladioli, taking the leading place with their collection, for twelve vases and six vases; while Mrs. Lucy Toner, Monaghan, Co. Amagh, was the winner in the class for twelve blooms of Begonias.

Mr. James Paul, Killearn, followed up his successes at Southport in the Pansy and Viola section by gaining the leading awards for twenty-four blooms of fancy Pansies, twelve blooms of fancy Pansies, and twelve blooms of Violas.

The feature of the decorative classes was the decorated dinner tables, for which there were fifty-three entries. Competition was very keen. First prize winners were, for Roses, Mrs. Dixon, Dumfries; Sweet Peas, Mr. A. L. Davidson, Bearsden; Carnations, Mr. William Berry, Lanark; and any other flower, Mrs. Kerr, Bearsden.

Fruits.

The fruit exhibits were a great advance on those of last year, the Grape and Apple classes being noted for superior quality and numbers. The Marchioness of Tweedale (gr. Mr. Alex. McBean) repeated her success at Southport, gaining the principal awards for a collection of twelve dishes, distinct varieties, which carried with it the *Glasgow Herald* Challenge Cup. While the fruits were of general excellence, Muscat Grapes were particularly fine in finish, and helped to secure 72 points, or half-a-point above the runner-up, Viscountess Cowdray (gr. Mr. William Smith), Dunecht. Mr. J. Davidson led with six dishes, his points totalling 40½.

The first prize and the Thomson Challenge Cup for eight bunches of Grapes, went to the Earl of Strathmore (gr. Mr. D. McInnes), Glamis Castle, who received 63 points for Muscat of Alexandria, Muscat Hamburgh, Gros Maroc and Black Hamburgh. The Earl of Mar and Kellie (gr. Mr. J. Buchanan), Alloa House, was second. The Sir John Reid Challenge Cup was awarded to Mr. Hugh McSkimming, Auchenault Gardens, Helensburgh, whose Muscat Grapes were beautifully finished. This exhibit also won a special prize for decoration. Mr. McSkimming also produced the best two bunches of Muscats, one bunch of Muscats, and the bunch with the finest bloom. Mr. James Duff, Threave, Castle Douglas, excelled in the two classes for Black Hamburgh Grapes, and Lord Rowallan (gr. Mr. J. Dixon), Kilmarnock, was first for Madresfield Court Grapes.

Mr. J. Davidson staged the finest collection of Pears, and he was also placed first in three other classes. Mr. Alex. McBean staged the best collection of fruits in the class confined to Scotland, and also scored with six Marguerite Marillat and six Souvenir du Congres Pears. Mr. R. A. Grigor, Dumfries, was the most successful competitor in the Plum classes; Mr. J. Duff excelled in the class for six Peaches, and the first prize for Nectarines went to Mr. A. McLean, Brookhurst, Bromborough.

Apples were outstanding in quality, especially the collection of six varieties grown by Mr. Alex. McBean, consisting of dishes of James Grieve, Emperor Alexander, Gascoyne's Scarlet, Cox's Orange Pippin and Peasgood's Nonsuch. The fruits were remarkable for their great size and high colour. The same exhibitor also excelled in the James Grieve and Cox's Orange Pippin classes, but had to be content with second place in the competition for twelve dessert Apples, first place being taken by Mr. W. Smith, who was also first for twelve varieties, orchard-house-grown. He also led in four other classes, including a collection of cooking Apples.

The following names were also prominent in the prize list for Apples: Mr. W. Campbell, Alexandria; Mr. Duncan McFie, Kames Castle Gardens; Mr. J. Blacklock, Drummond Castle Gardens; Mr. John Eason, Auchmore Gardens, Killin; Mr. J. P. Reid, Suningbrae Gardens, Aberlady; and Mr. J. S. Cowan, Doonholm, Ayr.

Vegetables.

This has been a good season for vegetables north of the Tweed, and the quality of the exhibits testified to first-class culture. Mr. R. A. Grigor was supreme in seven Potato classes, and the other honours were shared by Mr. W. S. Nash, Mauchline; Mr. James Alston, Mauchline; Mr. James Allan, Darvel; Mr. William Laidlaw, and Mr. William Hay. Mr. James Mills, Market Drayton, defeated Mr. John S. Cowan in the big Onion classes, but the latter was first for Shallots and twelve Onions grown from sets.

Tomatos formed a very large class, and the fruits were uniform in size and evenly coloured. Mr. Arch. Brownlie was first in the open class; Mr. D. Forrest, Carluke, carried off the chief prizes for twenty-four and twelve Tomatos; and Mr. James Duff led in the class for twelve yellow fruits.

New Plants and Flowers.

First Class Certificates.—Rose, Winnie Bell, shown by Messrs. Dobbie and Co.; a seedling Carnation, Mrs. D. Carlow, shown by Messrs. Torrance and Hopkins; seedling Chrysanthemums Robert McAlpine and Mrs. James Philp, raised by Mr. Alex. McAlpine, Tollcross.

Certificates of Merit.—Seedling Antirrhinum, raised by Messrs. Austin and McAslan; seedling Chrysanthemum, Afron, raised by Mr. Alex. McAlpine, and four seedling Violas, Ann Walker and Isobel, raised by Mr. Quinten McFadyen, Carluke; Nessie Douglas, raised by Mr. John Douglas; and William G. Whyte, raised by Mr. James M. Whyte.

Non-Competitive.

Trade exhibits were numerous, varied and attractive, and contributed materially to the success of the show. Six garden designs suited to the requirements of the modern cottage or bungalow type of residence were laid out and planted by the City Parks Department. Annuals, hardy perennials and shrubs were used in variety in the planting of beds and borders and various forms of hedging were introduced. A Large Gold Medal was awarded.

Two specimens of landscape gardening were provided by Messrs. Backhouse, Ltd., and Messrs. Austin and McAslan, and represented different examples of rock garden art. Each received a Large Gold Medal. The following awards were also distributed:—

Large Gold Medals.—To Messrs. Dobbie and Co., for Roses, Dahlias and Sweet Peas; Messrs. Austin and McAslan, for vegetables; and Messrs. Sutton and Son, for vegetables.

Gold Medals.—To Messrs. Samuel McGredy and Son, Portadown, for Roses; Mr. M. Rae, Biggar, for Begonias; Messrs. C. Engelmann, Ltd., for Carnations; Messrs. Laird and Dickson, Edinburgh, for alpines; Scottish Co-operative Wholesale Society, for Roses; Messrs. Allwood Bros., for Carnations; Messrs. Thyne and Sons, Dundee, for cut flowers; Messrs. Dobbie and Co., for Potatos and Orchid-flowered Dahlias; Messrs. Austin and McAslan, for Roses and Ferns; Mr. T. Smith, Newry, for shrubs and hardy plants; and Messrs. R. K. Gemmell and Co., for cut flowers.

Silver Medals.—To Messrs. Blackmore and Langdon, for Begonias; Messrs. Dickson and Co., for Roses; Messrs. Isaac House and Son, for Scabious; Messrs. T. Dagg and Son, for herbaceous flowers; Kippen Vinery Co., for Grapes; Messrs. Alex. Lister and Son, Rothesay, for cut flowers; Messrs. Leighton, for herbaceous flowers; Mr. Peter Aitken, Bathgate, for alpines; Messrs. Matthew Campbell and Son, Blaintyre, for Dahlias and border Carnations; Messrs. Fairbairn and Son, Carlisle, for Phloxes; Messrs. Storrie and Storrie, for fruits and pot plants; and Messrs. Williamson and Co., for Roses, Dahlias and alpines.

Bronze Medals.—To Messrs. John Forbes, Hawick, for herbaceous flowers; Messrs. Maxwell and Beale, for a rock garden.

Certificates were awarded to Messrs. Daniel Bros. Norwich, for Larkspurs and Gaillardias; and Messrs. Ramsbottom and Son, for Delphiniums.

ROYAL HORTICULTURAL.

September 10.—There was a particularly good show at the new Horticultural Hall, Westminster, in association with the fortnightly meeting of the Society on this date. Seasonable border flowers, particularly Michaelmas Daisies, Heleniums and secondary spikes of Delphiniums, were prominent among many other kinds, while there were many exhibits of Dahlias. Gladioli and Roses. The floral novelties were varied and interesting, and the Floral Committee recommended five Awards of Merit to novelties. The Joint Dahlia Committee inspected a large number of new Dahlias and selected the best for trial at Wisley. There were no groups of Orchids, but the Committee recommended two First Class Certificates and three Awards of Merit to novelties. There was a meritorious collection of pot fruits and several smaller exhibits, but no novelty of moment, before the Fruit and Vegetable Committee.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Frederick J. Hanbury, Mr. Richard G. Thwaites, Mr. J. C. Cowan, Mr. Fred. K. Sander, Mr. Robert Paterson, Mr. W. H. Hatcher, Mr. J. E. Shill, Mr. H. G. Alexander, Mr. Charles H. Curtis and Mr. E. R. Ashton.

Orchids were shown very sparingly on this occasion. No groups were exhibited in the hall, but ten plants were presented for the consideration of the Committee; Mrs. Carl Holmes, Gus Meyer, Esq., and Messrs. Charlesworth and Co., were among the exhibitors. The next meeting of this Committee will take place on Thursday, September 19, at 11 o'clock; and the following meeting will be on October 2 at the same hour.

First Class Certificates.

Laelio-Cattleya Titymona, Stonehurst var. (*C. Tityus* × *L.-C. Momus*).—A fine Orchid but scarcely up to F.C.C. form as compared with some shown recently. The sepals and petals are purplish-mauve, and the fine lip is deep crimson-purple with a golden-veined throat. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, Sussex.

Laelio-Cattleya Queen Mary var. Crimson Glory (*L.-C. Lustre* × *C. Peetersii*).—A fine, bold Laelio-Cattleya, with big, widely-expanded flowers. The sepals and petals are rich mauve-purple, while the splendid lip, neatly frilled, is of very intense, dark crimson-purple, a trifle paler in the front centre, and there is a small white spot on each side of the throat. The plant shown carried three handsome flowers on one spike. Shown by R. Paterson, Esq.

Awards of Merit.

Brasso-Laelio-Cattleya Golden Crown var. John Band (*B.-L.-C. Joan* × *C. Venus*).—A beautiful hybrid with flowers of good size and excellent substance. The sepals and petals are not so overlapping as in some hybrids, but they are of clear, bright, golden-yellow, while the wide, finely frilled lip is deep rosy-cerise, with old-gold veins in the throat. Shown by F. Mercer, Esq. (gr. Mr. J. Band), Clovelly, Steyning, Sussex.

Brasso-Cattleya The Duchess (*L.-C. Illustris* × *Brasso-Laelio-Cattleya The Baroness.*).—A showy hybrid, although not of the best form. The sepals and petals are clear golden-yellow and the lip deep yellow with a wide marginal band of pale rosy-pink. Shown by R. Paterson, Esq.

Laelio-Cattleya Cavalese, Stonehurst var. (*L.-C. Lustre* × *C. Fabia*).—The flower of this hybrid is of unusually rounded form, and carries very broad, rounded petals, which, like the sepals, are clear mauve. The rounded lip is deep rich purple, with a paler margin to the handsomely frilled edge. Shown by R. Paterson, Esq.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mrs. Ethel M. Wightman, Mr. D. Ingamells. Mr. James B. Riding, Mr. A. E. Vasey, Mr.

William Howe, Major George Churcher, Mr. R. Findlay, Mr. D. B. Crane, Mr. Charles E. Pearson, Mr. G. W. Leak, Mr. Courtney Page and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. G. Reuthe, Mr. W. G. Baker, Mr. Amos Perry, Mr. F. G. Preston, Hon. Henry D. McLaren, Lady Beatrix Stanley, Mr. A. Bedford, Mr. L. R. Russell, Mr. Reginald Cory, and Sir William Lawrence, Bart.

Awards of Merit.

Calluna vulgaris var. flore pleno.—This pretty and graceful double-flowered variety was found in Hampshire by the exhibitor. The variety has an exceptionally long central growth which, like the secondary shoots, is wreathed with double, pale pink flowers. Shown by Messrs. Maxwell and Beale.

Ixora lutea.—According to the *Botanical Magazine*, a plant of this species was received at Kew from the Royal Botanical Garden, Peradeniya, Ceylon, about a quarter-of-a-century ago under the name Ixora coccinea var. lutea. But, while it is allied to I. coccinea, I. lutea differs in its more lax inflorescence, the larger, ovate-rhomboid lobes and, of course, its yellow colour. The species is figured in *Bot. Mag.*, t. 8,439. A dwarf, well-grown plant bearing two trusses of creamy-yellow flowers was shown by Messrs. L. R. Russell, Ltd.

Pentstemon antirrhinoides.—This pretty, half-hardy, shrubby species was discovered in California by Dr. Coulter in 1824. Apart from the beauty of a well-grown plant, it is of special interest in having canary-yellow flowers, a colour which rarely appears in a genus of which most of the species are red-violet, purplish or blue. Unfortunately, the species is not hardy, but requires the protection of a wall, even in the warmer parts of the country. It is a small, freely-branching shrub bearing tiny, shining, opposite, ovate-acuminate leaves, and usually solitary flowers, terminal on the short side growths. A good illustration appears in *Bot. Mag.*, t. 6,157. Shown by the Director, John Innes Horticultural Institute.

Pernettya leucocarpa (*Comber* 501; 1926).—A low, creeping shrub from six inches to twelve inches in height. It differs from the well-known P. mucronata in its prostrate habit and softer, entire, small, linear leaves. The bush bore several clusters of relatively large, milk-white fruits. Shown by Lt.-Col. Messel, O.B.E. (gr. Mr. J. Comber), Nymans, Handcross.

Xanthosoma violaceum.—A warm greenhouse Aroid from the West Indies, and of uncommon appearance. The stems of the sagittate-ovate leaves and the flowers are of deep violet colour. The long spathe is bright yellow. Shown by Mr. Amos Perry.

Trial at Wisley.

Helenium autumnale var. Chipperfield Orange.—A not unattractive form of this popular autumn herbaceous plant, the golden-yellow blooms being lightly shaded with orange, but not sufficiently to justify the varietal name. Shown by Messrs. H. Simmonds and Sons.

Groups.

Just inside the hall, Mr. Amos Perry set up a pretty, low group of seasonable border flowers, which included his new Anthemis tinctoria Perry's var., the graceful little Tritoma Nelsonii, a goodly breadth of Verbena chamaedrifolia, Lapeyrousia grandiflora and Gentiana Farreri, while at one end there was a selection of aquatics. Collections of hardy border flowers were also shown by Mr. A. Miles, Dr. Septimus Pye, who included Dahlias and Chrysanthemums, Messrs. H. Simmonds and Sons, and the Misses Hopkins.

On a considerable wall space, Messrs. Barr and Sons set up a splendid collection of the best Montbretias, with large stands of Lilium sulphureum, L. auratum, L. speciosum var. rubrum and Romneya trichocalyx. Messrs. Hewitts had a very good exhibit of robust secondary spikes of many Delphiniums, and, near-by, Messrs. J. Vert and Sons showed a number of stems of double-flowered Hollyhocks bearing shapely flowers of very good colours. Messrs. B. Ladhams, Ltd., filled a long table space with useful border flowers, especially Michaelmas Daisies, Coreopses and Gladioli. Messrs. E. J. Redgrove and Son included a large vase of Physalis Franchetii and Michaelmas Daisies in their group of border flowers.

A goodly collection of Sweet Peas set up by Messrs. Dobbie and Co. included such beautiful varieties as Magnet, Mrs. A. Searles, Charm and Hero, while on the floor, they had fine strains of Zinnias and Marigolds of different types. Messrs. Hollamby's Nurseries filled a small table with ornamental Vines and Ivies. Messrs. Robert Veitch and Son had a miscellaneous collection of shrubs which included several varieties of Hibiscus syriacus, Myrtus Luma, Cornus Kousa and some well-fruited ornamental Crabs. Messrs. Maxwell and Beale had a small collection of Heaths.

A collection of particularly well-grown stove plants set up by Messrs. L. R. Russell, Ltd., included beautifully coloured Codiaeums (Crotons) and Cordylines, Ixoras in variety, Rondeletia speciosa and Dipladenia amoena var. John Peed. Various Eucalypti, Cannas and Ericas were grouped by Messrs. Stuart Low and Co. Especially good Roses were staged by Messrs. B. R. Cant and Sons, Messrs. D. Prior and Sons, Mr. J. H. Pemberton and Messrs. Wheatcroft Bros. In anticipation of the next day's show groups of Dahlias were staged by several growers. Messrs. Allwood Bros. and Messrs. C. Engelmann, Ltd., had their customary collections of fresh and fragrant Carnations.

A large floor space was filled by the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, Hertfordshire, with a great many splendidly grown plants of the Cape Scented Pelargoniums. Altogether nearly one-hundred-and-fifty sorts were represented, and a goodly number were duplicated. In addition to their charm of foliage, form and fragrance several sorts had distinct floral value; the chief of these were Clorinda, Edinburgh, Petersham Pet, Prince of Orange, Unique and echinatum var. album. Collections of Gladioli were staged by Messrs. R. H. Bath, Ltd., Messrs. Kelway and Son, Messrs. Dobbie and Co., Mr. H. Prins and Messrs. Daniels Bros., who also showed the useful Gaillardia Tangerine.

Joint Dahlia Committee.

Present: Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. J. Cheal, Mr. Robert Fife, Mr. D. B. Crane, Mr. Arthur Turner, Mr. James B. Riding and Mr. A. E. Vasey.

The Committee considered the merits of many novelties and selected the following for trial at Wisley:—

Schneider.—A Miniature Paeony variety of good form, with scarlet-crimson, velvety, waved petals.

Tunis.—A small-flowered Pompon Dahlia with fluted petals, terra-cotta on the outside, darkening to light crimson at the centre.

Darjeeling.—A shapely, Miniature Paeony variety, the recurved petals being bright orange, yellowish on the reverse and at the base.

Bhopal.—A Miniature Paeony Dahlia with bright orange-scarlet flowers.

Faygate Star.—The curved petals of this variety are orange-scarlet, with the margins curled back to give them a very slender appearance. This, and the four preceding varieties, was exhibited by Messrs. J. Cheal and Sons.

The Ranee.—A dark-foliaged Miniature Paeony Dahlia with bright scarlet blooms of good form. Shown by Mr. A. J. Cobb, Reading University.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. H. S. Rivers, Mr. W. H. Divers, Mr. H. V. Taylor, Mr. H. Markham, Mr. E. Neal, Mr. E. Beckett, Mr. A. Bullock, Mr. A. Poupart, Mr. F. Jordan, Mr. C. G. A. Nix, Mr. J. Cheal and Mr. A. Rawes, Secretary.

Other than the naming of fruits and the inspection of two seedling Apples, which were considered to be inferior to existing sorts, this Committee had very little to occupy its attention.

Groups.

Messrs. T. Rivers and Son arranged an excellent group of fruit trees and vines in pots, all the specimens being of very healthy appearance and heavily laden with fruits. Plums were represented by President, Coe's Golden Drop and the richly coloured Late Orange; Peaches by Sea Eagle, Nectarine Peach, Prince of Wales and Princess of Wales; and Nectarines by Spenser, Byron, Stanwick Elruge, Darwin and Pineapple. Peasgood's Nonsuch, Worcester Pearmain and James Grieve were among the Apples staged in this excellent group.

Messrs. Stuart Low and Co. associated a few dishes of Apples with their collection of pot plants, and Mr. J. J. Kettle showed fruiting sprays of Raspberries Perpetual Giant, red and Lord Lambourne, golden-fruited.

Messrs. B. Ladhams, Ltd., showed a dish of excellent fruits, together with heavily laden sprays, of Blackberry Shirley Prolific.

BARE HORTICULTURAL.

The Bare Horticultural Society had a fine day, a record number of entries, and a good attendance on the occasion of its eleventh annual exhibition, at Happy Mount, Morecambe. The Mayor and Mayoress of Morecambe opened the show.

The Waddilove Cup, for the most points in the open flower section, was won by Mr. Frank Smith, Bare; the Ceres Ridge Bowl, for the best collection of cut flowers (open), by Messrs Ratcliffe and Tomlinson, Bare; the Overend Cup, for the best collection of vegetables (amateur and cottagers), by Mr. J. Parkinson, Bolton-le-Sands; and the Bare Institute Trophy, for the best trade exhibit, was won outright by Messrs. Webb and Co., Kendal.

In the fruit classes, Mr. T. Cole, Torrisholme, carried all before him, as did Mr. W. Robinson in the open vegetable classes. Trade exhibits were staged by Messrs. Webb and Co., and Messrs. G. Gibson and Co., Leeming Bar, the latter staging a fine exhibit of cut Roses.

DUMBARTONSHIRE SWEET PEA.

The twelfth Annual Show of this Society, which was held at Dumbarton during August, was the most successful in its history. The number of exhibits created a new high record; there was a better attendance of the public, and the quality of the blooms was surprisingly good considering the unfavourable weather conditions. There were forty-eight classes and these were mostly well filled.

In the open section for Sweet Peas, Mr. Charles Glass, Cardross, defeated Mr. James Paul, Killearn, in the class for eighteen vases, and Mr. George Ballingall, Dumbarton, was first for twelve vases, and for six vases with well-grown examples of Youth, Chieftain, Flamingo, What Joy, Jessie and Powerscourt.

Mr. F. G. Dunbar, Kilmahew Gardens, Cardross, was the most successful exhibitor in the gardeners' and amateurs' section. He won the Society's Cup for the best twelve vases for the third year in succession, carried off the special prize for nine vases, and was placed first for three vases, and for the vase of a cerise variety.

Roses were a superior class. A feature was the success of Mrs. Russell, Newton-Mearns, in the open and gardeners' and amateurs' classes. Out of six exhibits staged she was awarded five first prizes, while her vase of Mrs. A. R. Barraclough received special recognition as the best vase in the show.

Carnations were not numerous, but the quality was good. Here Mr. James Smith, Darvel, excelled in the class for three vases, and he also staged the best decorative vase and the best vase in the show.

Bouquets were well represented in the Decorative section, and chief honours in both classes were credited to Mr. William Holmes, Junr., Helmsburgh, who was also responsible for the best basket of Sweet Peas.

Trade exhibits consisted of Roses by Messrs. Austin and McAslan, Glasgow, and Sweet Peas, by Messrs. Dobbie and Co., Edinburgh.

ANSWERS TO CORRESPONDENTS.

Cuttings of Black Poplar.—*E. G. M.* Cuttings of Black Poplar may be made at any period between the fall of the leaves and the end of February. It is usual to take well-ripened shoots—anything from half-an-inch to a quarter-of-an-inch in thickness—cutting them to about one foot in length and burying the lower nine inches in the soil. Much larger cuttings, however, are sometimes used, particularly when cuttings are to be inserted in the positions that the future trees are to occupy. When the cuttings have to be inserted in a nursery the small ones are the kind that should be used. They will commence to grow early in summer and probably form shoots three feet long by autumn. They may be transplanted and kept in the nursery for a second year, or they may be planted into permanent positions direct from the cutting bed. A second year in the nursery is, however, advisable. The tree that is usually known as Black Poplar is Populus serotina, and you should find no difficulty in procuring cuttings. If you know of anyone who possesses large trees they will probably give you what you require, or charge a small amount. Should you not know anyone, if you write to Messrs. Hillier and Sons, Nurserymen, Winchester, they would be able to supply cuttings, or small plants.

Disagreement over Letting of Garden.—*E. F. B.* From the information before us, it would appear that all the terms of the proposed letting were not definitely agreed, and this view is supported by the fact that the owner started negotiations elsewhere after you had informed him you did not intend to proceed. Unless your letter amounted to a contract to take the place, you should not pay anything.

Gladioli Diseased.—*H. P.* The Gladioli are suffering from Fusarium wilt disease. Little is known at present as to the reason for the sudden infection of the corms. Destroy by fire all infected corms, skin healthy corms and soak them in a two per cent. formalin solution for half-an-hour prior to planting next year; replant them in fresh soil as far removed from their present position as possible. Infected corms cannot be saved.

Large Insect in Greenhouse.—*B. S.* The insect caught flying in the greenhouse is known as the Giant Wood Wasp, Sirex gigas. The larvae bore into the stems of Pine and Larch trees, especially if the trees are unhealthy. The species is widely distributed in Britain. The larvae are often present in imported timber, which, if stacked for some time, allows the life cycle to be completed so that the adults emerge in districts far removed from where the eggs were deposited.

Lime Trees Harmful to Bees.—*N. T. B.* It is quite true that at least one Lime tree has harmful effects upon humble bees, but these effects have not been noted in the case of hive bees. This particular Lime is Tilia petiolaris, and it is one of the most handsome of all Limes. A Lime tree that is almost equally good is Tilia euchlora. This has very bright green leaves, and it flowers later than the common Lime. The leaves do not become dirty by honey-dew, and it keeps its fresh appearance until the leaves fall; this Lime would probably be the more satisfactory one for you to cultivate. So far as observations have gone, it is not harmful to bees.

Muscat Grapes Discoloured.—*H. W.* The Muscat Grapes indicate that the plants have received more than sufficient water for their requirements. The cemented border is a disadvantage, for the operation of watering, always difficult in the case of Vines, is rendered more so. Maintain a drier atmosphere, and do not remove any of the laterals or foliage as these allow plants to get rid of excess water. The rusty appearance of the berries is brought about by draughts, so that the ventilation of the house must receive greater attention.

Name of Fruit.—*A. S. M.* Apple Duchess's Favourite.

Nymphaea Foliage Diseased.—*W. G. G.* The Nymphaea foliage is infected with the fungus, Ramularia nymphaearum. Remove and burn infected leaves and drain off old water and refill the pond with a fresh supply. The presence of rock salt in the water is decidedly distasteful to these plants.

Palm Foliage with Scale.—*M.* The Palm leaf is heavily infested with a scale insect, Aspidiotus species. The foliage should be sponged with a one per cent. solution of Volck, and washed afterwards with clear water. The yellow band on the leaf is due to the absence of light, caused by the overlapping of other leaves. There is no sign of disease in these areas.

Peaches and Nectarines Unhealthy.—*D. M.* The Nectarine fruits and leaves were badly attacked by thrips, a very small insect, possibly introduced by plants of some kind, such as Azaleas. When allowed to increase they become very troublesome and destructive, as they destroy the foliage by feeding along each side of the midrib, and attack the fruits at the apex, which causes the skin to dry up and crack. Thrips are seldom found if good daily syringing with clear, soft water is practised. If syringing is neglected, or carried out in a careless manner, thrips will appear as a natural consequence. One fumigation with XL All, or syringing with XL All Insecticide or Tabacco water generally kills the old insects, but it has no effect on the nymphs (young), so it should be repeated three times in about ten days, and alternated by forcible syringings with clear, soft water. Dress the trees with Gishurst Compound during the winter months when dormant and clear of leaves. The shoots of the Royal George Peach were shrivelled, and appeared healthy, but weak. If you suppress the strong shoots next year by pinching, and allow the weaker ones to grow, the balance of the tree will be righted.

Stocks for Apples and Pears.—*H. G. M.* You can buy the various stocks for budding and grafting Apples and Pears from almost any fruit nurseryman during the winter and spring months. Seedling stocks embrace a very broad range (see p. 200), and may be grown from cider refuse, but it is much better to have selected stocks. The seedling Apple may be used for free fruiting varieties but not for strong growers. Crab stock is used for standard or orchard trees and also for weak-growing varieties. The various forms of Paradise are layered, and are best for pyramids, bushes and cordons, and all more or less tend to encourage the early production of fruits. The same remarks apply to the Quince stock, which is best suited for pyramid and bush Pears. The Pear stock is generally used for standard trees, and in some cases for the weak varieties.

Tomato Plants Failing.—*H. C. W.* We fail to find any parasitic fungi on the Tomato plants. The symptoms suggest that the trouble is due either to faulty fumigation, or that the compost in which the plants are growing is entirely unsuitable. The plants appear to have received a check, and show no desire to make further growth. The continued use of the same soil will induce this condition and may be remedied by steam sterilisation and the addition of fresh loam to the compost. It may be advisable to try the effect of small dressings of nitrate of soda to see whether they will break away.

Tomato Fruits Splitting.—*D. J. H.* (1) Some Tomato varieties are more susceptible to splitting than others. Splitting is usually caused by irregular watering. The skin becomes hard when water is withheld, and a sudden swelling of the cortex, following the application of copious water, bursts the hard skin. (2) Green Back of Tomato fruit is caused by exposure to strong sunlight, and is frequently produced when too much foliage has been removed. Plants receiving too little potash are most susceptible to this disorder. (3) Usually 17,000 Tomato plants are allocated to one acre. The plants are set out one foot apart in rows; the rows are alternately eighteen inches and twenty-seven inches apart, the wider rows offering sufficient space for the workers. Under these conditions the average yield is about 5¼ lbs. per plant. (4) The cost of heating four Tomato houses, each 200 feet by 30 feet, should not exceed £250 per year.

Vines Unhealthy.—*N.H.* The Vine shoots and leaves sent for examination rather suggest that your Vines are suffering from the Vine louse, Phylloxera, but this could only be confirmed by a thorough examination of the roots. The trouble is largely due to excessive dryness of the roots, which have possibly been neglected for a number of years. As you have decided to replant the remainder of your border, you ought certainly to remove the two young canes you have planted in the old border, especially as they are affected. You will then be sure of removing the cause of your trouble.

Viola and Apple Leaves Unhealthy.—*A. W.* The Viola foliage is infested with red spider, and should be sprayed with Volck, the lower surface of the leaves receiving special attention. If the plants are dying off the cause is probably a root-rot fungus, in which case we must have an entire plant to examine. The Apple leaves show no sign of disease, and the mottled appearance suggests that the cause is either due to spraying with an oil wash applied in bright, sunny weather, or that the hot ashes of a garden fire have been distributed over the plant. It is not typical leaf-scorch.

Violas Dying Off.—*W. A. T.* The roots of Violas are liable to be attacked by fungus diseases as well as live creatures in the soil. What you call wireworms are probably one of the snake millipedes, namely, Blanjulus pulchellus, judging from your description. The roots may also be destroyed by a species of Fusarium, and also Phytophthora terrestria, both fungi. We do not think you will be able to grow Violas among Roses for more than one or two years, because the soil is too rich in decaying vegetation and cannot be trenched. You could plant Nepeta Mussini among Roses, or some other low-growing plant, and select a piece of ground for Violas that can be trenched thirty inches to two feet deep, and manured in the autumn. Turn the top spit into the bottom, and bring up the lowest spit to the top, laying it up in ridges for the frost, rain and air to sweeten. The millipedes may be driven away by dusting the ground among the Roses with lime and soot occasionally, and by hoeing the ground frequently during the summer and autumn. The chief enemy of the Stocks is most likely the fungus, Phytophthora terrestria, otherwise named P. hypogaea. The trouble is usually contracted in the seed-boxes. All soil for seed-sowing should be sterilised with boiling water for half-an-hour and then dried before use. Plenty of air should be given to Stocks from the time they germinate until planted out, to dry up surface moisture, and care should be exercised not to overwater them.

TRADE NOTE.

An error occurred on p. 192 of our issue of September 7. The honour of winning the premier award in the Southern Class for a group of Roses, forty feet by four feet, at Southport, belongs to Messrs. Frank Cant and Co., Ltd., and not to the firm to whom it was credited.

Potato Virus Diseases: Leaf Roll.

IN our issue of September 14, p. 197, an account was given of Dr. Kenneth M. Smith's work on the relations which obtain between the Aphis, Myzus persicae, and the virus disease of Potatos known as Mosaic. In this work it was definitely shown that, whereas under experimental conditions this Aphis has not so far been shown capable of transferring the virus of Mosaic disease from one Potato to another, yet it can undoubtedly carry the disease, for when kept in contact with Potatos stricken with Mosaic disease, Myzus persicae, when transferred to Tobacco plants, sets up a malady therein, which malady when retransferred to the Potato appears as a virulent form of Mosaic. Even less obscure is the part played by the Aphis in disseminating Leaf Roll, another virus disease of the Potato. Just as is the case with other virus diseases, a specific agent appears to be the carrier. One species of Leaf Hopper, and apparently one only, carries Streak, a virus disease of Maize, so with Leaf Roll, Myzus persicae is the only known carrier. Once the Aphis has inoculated itself with it, the virus persists for a long time in its system. Thus, infective Aphides kept for so long as seven days on an indifferent host plant (Cabbage) still retain their power of infecting Potatos with Leaf Roll. Nevertheless, the virus, according to Dr. Smith's investigations, cannot be handed on from one generation of Aphis to the next. For which relief much thanks! When the Aphis is harboured by a Potato plant suffering from numerous virus diseases, the only one which it can effectively transfer to a healthy Potato is Leaf Roll. Once the Potato is inoculated with the virus it takes about from eighteen to thirty days for the symptoms to develop. In all, some seven varieties of Potato have been used in these experiments, and there seems to be no ground for believing that any variety can offer any marked measure of resistance to Leaf Roll. All appear to be equally susceptible. As illustrative of the virulence of the virus of this disease, Dr. Smith compared the effects of transferring to Potatos few or numerous Aphides of the carrier species which had been in contact with Potatos affected with Leaf Roll. The few (two) Aphides were just as potent in inducing the disease as the many. Hence, it is to be concluded that a very little virus goes a very long way, and, indeed, it cannot be doubted but that the virus, although it may not be regarded as a micro-organism of ordinary kind, nevertheless possesses the typically vital property of multiplying itself. Whether, after all, these viruses will prove actually to be micro-organisms of extreme minuteness, cannot at present be stated. The fact that they are filter-passers, that is, may be filtered with unimpaired powers through a Pasteur Chamberland filter, is not in itself evidence against viruses being micro-organisms, for there are known to exist certain bacteria and other microscopic forms of life which can be filtered. Dr. Smith's contributions to the many problems relating to Virus diseases of Potato are so valuable that we hope it may be possible soon for him to bring them together in a more connected form.

Our Supplement Plate.—The subject of the Supplement Plate presented with this issue is Ostrowskia magnifica, a plant of singularly noble aspect, but which does not thrive in all places and is often disappointing. Instructions for its successful culture are voluminous, but in reality it is one of those plants which are by nature capricious and require for their well-being just that one position so difficult to find. A deeply-worked soil and a copious supply of old mortar or brick rubble, with a warm, sheltered situation, would appear to offer the best chances of success, and when once happy, the plants should enjoy immunity from disturbance. The Carrot-like roots—they will penetrate to a depth of two feet or more—are very brittle, so that careful handling is essential. Seeds of O. magnifica may be germinated in a cold frame, but some years elapse between sowing and flowering—a small matter when the ultimate reward is so great. Seedlings usually display slight variations from the type. The huge blooms, reminiscent of a glorified Platycodon, are delicate greyish-mauve, suffused with white, and as the stems will tower to a height of several feet—plants of over eight feet have been recorded—the plant is of stately appearance. The Supplement Plate depicts a plant flowering in the gardens of Watermoor House, Cirencester, the residence of Thomas Kingsate, Esq., C.V.O. The height of this specimen was seven feet four inches; the diameter of an individual bloom was six-and-five-eighths inches. This plant is growing in a position shaded from the morning sun, and is in close proximity to a large shrub-covered rock; the soil is deep, well-drained and rich in humus and the plant has occupied its present position for some years, four at the least.

Southport Flower Show.—The great flower show held annually at Southport was established in 1924, when the attendance was 45,394 and the revenue £3,354; in the following year the figures rose to 58,554 and £4,535, respectively; in 1926, the visitors numbered 67,514. and the income came to £8,896; in 1927, there were 84,087 visitors, and the receipts amounted to £10,370, but in 1928, a wet season, there was a drop in attendances to 82,653, although the takings increased to £11,275. Success has been continuous, and this year the attendance records were as follow:—Wednesday, August 28, 24,847; Thursday, August 29, 49,727; Friday, August 30, 24,586, or a total of 99,160, while the takings amounted to the handsome sum of £13,040. The Flower Show Committee hoped the attendance would reach the 100,000 mark, but although this hope was not realised, no one was disappointed with the result.

Dutch Method of Preserving Potatos.—A method of preserving Potatos for feeding to stock, as practised by Dutch farmers, is described by Mr. T. Dunlop in the *Scottish Journal of Agriculture*, 12, p. 318. After first washing the tubers, they are steamed in as little water as possible, and when the liquid has been poured off they are packed firmly into pits three feet deep. Old Jute bags are placed over the Potatos, and these are covered with a layer of soil about a foot deep; if the climate is wet the pits are thatched over. When so treated, and provided the packing is done carefully, so that all air is excluded, the Potatos keep in good condition for a number of years. Salt is needed before feeding the Potatos to stock, if it was not added during the process of steaming. The total cost of labour, etc., for treating the Potatos is estimated at 2s. a ton, and it is stated that very little depreciation in feeding value and flavour occurs as a result of the steaming and storing.

Honour for Sir William Lawrence.—Our congratulations to Sir William Lawrence, Bart., Burford, Dorking, upon whom the French Government has conferred the honour of Officier du Merité Agricole, for services to horticulture.

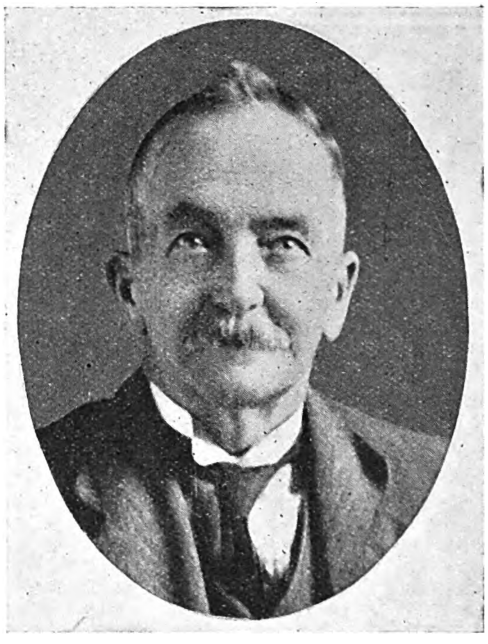
Captain F. Kingdon Ward.—After a trying experience in Indo-China—including a month's illness up country—Captain F. Kingdon Ward has returned safely from his short trip to the Far East. He reports that the weather was atrocious, and that illness among members of both the American expeditions that he arranged to meet, upset many plans.

John Cypher Memorial Fund.—The following amounts have been received for the Memorial to the late Mr. John Cypher, V.M.H., since the publication of the first list of subscribers:—Mr. R. Windsor Rickards, Usk Priory, Usk, Mon., £2 2s.; Mr. W. T. Mitchell, The Arboretum, Westonbirt, Tetbury, 10s. 6d.; Mr. H. J. Chapman, Mornington, Wylam-on-Tyne, £1 1s.; Mr. Edwin Beckett, V.M.H., Aldenham House Gardens, Elstree, £1 1s.; and Mr. A. J. Cobb, The University, Reading, £1 1s. Subscriptions to this fund should be sent to the Hon. Sec. and Treasurer, Mr. Charles H. Curtis, 5, Tavistock St., Covent Garden, London, W.C. 2.

Retirement of Mr. J. T. Butters, Port Elizabeth, South Africa.—We learn that owing to advancing years, Mr. J. T. Butters retired, at the end of June, from the position of Superintendent of Parks and Gardens, Port Elizabeth, South Africa. He held this position for forty years, and is being rewarded for his long and meritorious services by a pension which will enable him to live in comfort. During the time Mr. Butters had charge of the gardening and tree-planting, Port Elizabeth has been transformed from an almost treeless, desert-like place, to one of very considerable attractions. Plantations abound, and create a totally different impression to that gained by visitors who only know the sea-front. With but little soil and vicious winds during the spring and summer months, it was no easy task to find trees that would thrive under these adverse conditions. They were found, however, and the tree which most successfully withstands the local conditions is Pinus halepensis. A few species of Eucalyptus do moderately well, although they are apt to show dead top shoots after droughts and after being battered by the winds, or scorched by the saline spray. In sheltered places Harpephyllum caffrum does fairly well, but those places are very few indeed. In a suburb only about three miles away, sheltered by the hills, where the soil is generally of a sandy nature, Pinus insignis and a number of other trees do well, but they are mostly useless at the port. P. halepensis, when once established, is able to hold its own, and as groups and belts of it were planted thickly they now form a fine feature. At a farewell gathering, the Mayor, on behalf of the officials, made a presentation to Mr. Butters, and said that the parks were a feather in the cap of Mr. Butters and the envy of other places in South Africa. Mr. Butters had been a friend of all the sporting societies in the city in connection with the laying out of grounds for playing fields. The Town Clerk, in appreciation of Mr. Butters as a colleague, referred particularly to his magnificent work in improving the amenities of the golf course by means of tree planting. There, he said, the wind-swept veldt had been converted into a place of real beauty, and the woods were much admired by all who visited the links. In St. Georges, the headquarters of the Parks Department, Mr. Butters had got together a fine collection of shrubs, trees, succulent plants, etc.; recently a new nursery ground has been made where all the young trees and plants are raised. There is in this nursery a fine collection of Palms and other suitable subjects used for decorating. During the last two summers the task of carrying on the work has been very trying indeed, for the city has outgrown its water supply, and, to make matters worse in this respect, the usual rains have not fallen in the catchment areas of the reservoirs, consequently the use of water for gardens has been, and still is, strictly forbidden. But in spite of that, water was carted from a small stream a little distance away, and most of the trees and plants were kept alive. Mr. Butters retires full of years and of honour, his life's work well done.

Paper from Bamboo.—We learn from the Government Report issued by the Forest Research Institute at Dehra Dun, India, that Mr. W. Raitt, the officer in charge of the paper pulp section, has carried out some useful experiments in the manufacture of paper from Bamboo stems. At present the only areas which have been considered for the production of Bamboo stems for paper-making are those in Burma, which are estimated to produce 800,000 tons of pulp per annum, and the plantations are within three miles of a river which could be used for transporting the canes to the pulp-mill. Should the demand be sufficient to encourage the formation of improved methods of transport, much larger areas could be brought in. When timber forests are cut down for the use of the saw-mill or pulp-mill the land is cleared, and unless re-afforestation is systematically carried out, the supply from that area is gone for ever. Even with regular and systematic tree-planting, it takes many years for the trees to grow to a size to fit them for the pulp-mills. With Bamboo, however, the plant is practically indestructible, except by uprooting, or by seizing the opportunity afforded by seeding to uproot the young seedlings. After cutting, the plants commence growth again, and are ready for cutting in from five to seven years. In view of these facts, it would seem that Bamboo affords an inexhaustible supply of raw material suitable for paper-making. In the earlier stages, the experimenters were faced with what appeared, at the time, to be an insurmountable difficulty. One-fifth of the weight of the material consisted of a peculiarly malignant type of a chemical substance known as pectin, which in combination with the soda which was used to break down the fibre, formed a dark brown dye, which the pulp absorbed. This had to be got rid of at a later stage in the process by the use of an excessive quantity of bleach, which not only made the cost of the pulp almost prohibitive, but was very destructive of the fibre. It has been found, however, that the pectin is soluble in weak solutions of soda at a temperature not high enough to break down the material into fibre, and the pectin is now dissolved and run off before actual pulping takes place. As regards the cost, it is calculated that in spite of the great distance from Burma to this country, the Bamboo pulp could be brought here and sold at a price to compete successfully with Scandinavian wood-pulps of the same quality, and allow a good margin of profit to the pulp-mills in Burma.

Mr. Frederick Bright.—Mr. Frederick Bright was born in 1853, at Weston, near Bath, where his father was head gardener. He commenced his gardening career under Mr. W. Parsons, at Bittow Rectory, and eventually served his apprenticeship under Mr. Bartram, a famous Grape grower in his day, at Cyfarthfa Castle, Merthyr Tydvil, Glamorganshire. From there he went as journeyman-gardener to Mr. Worthington, Westbury-on-Trym, another famous fruit-grower and exhibitor. Later he obtained the post of indoor foreman under Mr. John Bushel, at Redland Court, Bristol, and in 1883 he was appointed head gardener to the late Mr. Preston Carslake, at Whiteknights Park, Reading, where he soon became famous as a plant and fruit grower. In 1899, Whiteknights Park was acquired by Jules Friedlander, Esq., and Mr. Bright continued in his service as gardener and estate manager, retiring in 1920, after thirty-seven years' service at Whiteknights Park. During his time there he trained many young men who to-day are holding responsible positions in the horticultural world. He has two sons and two daughters. His elder son is head gardener to Captain Philpot, Sandroyd House, Cobham, and is well known as a grower of specimen Chrysanthemums, and the younger son is head gardener to Major Disraeli, Hughenden Manor, High Wycombe, Bucks. Mr. Bright was a noted cultivator of specimen Fuchsias, for which he gained many awards, notably at Holland House, and later at the London International Exhibition in 1912, where he was awarded a Silver-gilt Medal and Diploma of Honour for a group of specimen Fuchsias; a Silver-gilt Medal for a group of Schizanthuses; and a similar award for a group of Mignonette in pots. He has raised many greenhouse and outdoor plants in his time. Many are in commerce to-day, such as Fuchsia Whiteknights Gem, and F. Pink Pearl, and a very fine bedding Pelargonium named Whiteknights Glory. He was successful in crossing the Clivia with the Hippeastrum, and the late firm of Messrs. James Veitch and Sons, Chelsea, acquired the whole stock of the resulting hybrids. Mr. Bright, who now lives at Westbrook, Shinfield, Reading, still takes a very keen interest in gardening, particularly in hardy fruits. On the east side of his house he has planted and trained a Peach tree, of the variety Dymond, which is a model of perfection, and covers a space of thirty feet by twelve feet. This year the tree is carrying some three hundred fruits, beautifully spaced out at about a foot distant from each other. Mr. and Mrs. Frederick Bright celebrated their golden wedding at Westbrook, on August 7, in the company of their family and a large number of friends. Mrs. Bright is the second daughter of the late Mr. James Lye, who was gardener at Clyffe Hall, Market Lavington, Wiltshire, and famous in the horticultural world for raising and introducing many grand Fuchsias.



MR. FREDERICK BRIGHT.

Mr. M. Audley F. Sutton.—The youngest partner in the firm of Messrs. Sutton and Sons, Reading—Mr. M. Audley F. Sutton, son of Mr. and Mrs. Martin Sutton, of Erleigh Park, Reading—was married a few days ago to Miss Joan Lehmann, daughter of Mr. and Mrs. S. P. Lehmann, of Woodford Green. The wedding took place at St. Paul's Church, Portman Square, London, and was attended by a very large number of the members of the staff at Reading.

Small Holdings in the Island of Harris.—The Government has exercised its powers to acquire land compulsorily for small holdings, in the case of the deer forest of Luskentyre, in the Island of Harris. The Luskentyre estate is nearly 6,000 acres in extent, and is the property of the trustees of the late Lord Leverhulme.

Early Autumn Flowers in Regent's Park.—Despite the long-continued drought, the early autumn display of flowers in Regent's Park is equal to those earlier in the year, for the numerous beds and borders are now gay with Dahlias, Chrysanthemums, and other seasonal flowers. Upon entering the park by the Park Square entrance, the visitor is confronted by a magnificent bank of Dahlias, tastefully arranged, and every plant laden with blooms. Every type of Dahlia is represented, and the number of varieties must run into three figures, while the edging of the bed is of numerous Single and Mignon sorts. The display of Dahlias at the Clarence Gate is almost equally as grand. The beds along the main avenue are planted chiefly with Chrysanthemums, the leading sorts employed being Madame Marie Massée, Elstob Yellow, Pluie d'Argent, Crimson Polly, Ralph Curtis, Golden Diana, Major Robertson and Mrs. Pearson. Among Dahlias used in the bedding schemes are the free-flowering, rich pink Rose Orleans; Prestige, over a groundwork of the dwarf bedding variety Averrood; and Bishop of Llandaff, a grand, vivid scarlet Paeony-flowered sort with dark foliage. The bed of Lobelia cardinalis is very striking, while another pleasing effect has been obtained with the floriferous Petunia Silver Lilac as a groundwork to standard Fuchsias. The long herbaceous border is looking very parched; in this, the dominant colour is yellow, and although, of course, this can hardly be avoided, the introduction of a few other colours would add considerably to the decorativeness of the border. However, the general effect of the floral schemes in Regent's Park is very fine and reflects great credit upon Mr. Campbell and his staff, who achieve so much under conditions which are far from congenial.

Mrs. A. Sherman Hoyt's Gift of Cacti to Kew.—Our readers will remember that Mrs. A. Sherman Hoyt, Pasadena, California, exhibited a wonderful collection of Cacti and other succulent plants at the Royal Horticultural Society's Chelsea Show. The exhibit was described and illustrated in *The Gardeners' Chronicle* of May 25 and June 1, 1929, while a portrait and appreciation of Mrs. A. Sherman Hoyt were given in our issue of May 25. The valuable collection, comprising about one-hundred-and-fifty plants, together with a large quantity of natural stone and sand, was transported from California to London with such success that not a single plant suffered injury. At the close of the Chelsea Show, Mrs. Hoyt most generously presented the collection to Kew, and, as stated in the current issue of the *Kew Bulletin* (No. 7, 1929), the plants are now installed in the Succulent House. A portion of the bed at the north end of the house has been cleared for their reception; and the native stone and sand have been utilised in giving the plants as natural a setting as possible. This arrangement preserves its general interest, and, at the same time, demonstrates its educational value. Among so many magnificent plants several are new additions to the Kew collection. The following are particularly noticeable on account of their size and grotesque appearance. Ferocactus Lecontei, Britton and Rose, is represented by three large specimens, each with a stem over three feet high and eighteen inches in diameter, covered with a thick network of stout spines of a reddish colour. In several smaller plants the spines are a brilliant red. Echinocactus polycephalus, Engelm. and Bigelow, of which there are several fine specimens, is remarkable in having from six to fifteen stems which spring from the same base. The stems are from fifteen to eighteen inches high and ten or twelve inches in diameter, and are covered with exceptionally stiff spines. Echinocereus Engelmannii, Rümpler, is a very distinct species with great numbers of long, straight, crowded spines which completely hide the stem and look like a stiff bottle-brush. Among the several plants of this species there are three distinct varieties, differing chiefly in the colour of their spines. The largest specimen consists of thirty stems and is over a yard wide. A very handsome plant is an unnamed Opuntia which may be O. strigil, Engelm., a rare plant in cultivation. It is four feet high and well branched, the joints being covered with numerous long, yellow spines. Another well-marked and pretty species is Opuntia Davisii, Engelm. and Bigelow, with slender joints and long, yellow spines. A very singular plant, which does not belong to the Cactus family, is Fouquieria splendens, Engelm. This shrub produces long, slender, prickly branches from the base which reach a height of eight feet. The bright red flowers are borne at the tips of the branches. It is reputed to make an effective and almost impenetrable hedge. Other genera are represented by several species of Cereus, Mammillaria, Agave and Yucca. This gift is greatly appreciated, and visitors to Kew have expressed the greatest interest in Mrs. Hoyt's unique collection of desert plants which she has so generously presented.

Legacies to Gardeners.—Dame Margaret Annie Knott (wife of Sir James Knott), of Close House, Wylam-on-Tyne, who died at Cannes on March 8, bequeathed to her gardener, Mr. William E. Anderson, a sum equivalent to five years' salary; five years' salary to Mr. Harry Thompson; two years' salary to Mr. W. Beattie; and one year's salary each to Mr. Jack Tait, Mr. R. Moffatt and Mr. Robert Trail—all under-gardeners; while Ada Jordan, the bothy caretaker, also received five years' salary. Mr. Calvery Bewick, the owner, has now returned to Close House, and has engaged Mr. Anderson as his gardener.

Sweet Peas for Garden Decoration.—The Floral Committee of the National Sweet Pea Society recommends the following twenty-four varieties of Sweet Peas for general garden cultivation:—Ascot, pale pink; Avalanche, white; Bonfire, bicolor; Charming, deep cerise; Corona, rose; Delightful, rose cerise; Elegance, blush-lilac; Grenadier, scarlet-cerise; Huntsman, scarlet; Ivory Picture, ivory; King Mauve, mauve; Magnet, deep cream-pink; Mrs. Arnold Hitchcock, pale cream-pink; Mrs. H. J. Wright, flushed, white ground; Olympia, purple; Picture, cream-pink; Pinkie, deep pink; Powerscourt, lilac-lavender; Reflection, blue; Sybil Henshaw, crimson; Tom Webster, medium blue; Warrior, maroon; Wembley, pale lavender; and Youth, picotee-edged.

Appointments for the Ensuing Week.—Monday, September 23: Harrogate and District Horticultural Association's meeting; National Chrysanthemum Society's Floral Committee's meeting. Tuesday, September 24: Post Office Savings Bank Horticultural Society's Exhibition; Royal West Renfrewshire Horticultural Society's meeting. Wednesday, September 25: Newcastle and District Horticultural Society's meeting. Saturday, September 28: Leigh-on-Sea Horticultural Society's Exhibition; Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Bursting of Trees in Frosty Weather.*—I have hitherto accounted for the bursting of large trees under the influence of excessive cold, by attributing it to the expansive force of the sap while undergoing congelation; but this theory seems now to be set aside by Professor de Vriese's explanation of the fact, according to which we are to suppose that the tree goes on feeding like Jack's giant, till it is obliged to slit itself open for ease, the cold not permitting the trunk to expand. Now, without disputing for a moment that the sap does circulate to some extent during winter, I am really not prepared to charge trees with such monstrous gluttony, especially in cold climates, where the phenomenon usually occurs. In the same countries rocks split as well as trees; are we to apply the same mode of reasoning to them? Again, the professor attributes the destruction of flower buds by cold to the evaporation of their juices by the wind; but how will this account for their destruction when, as often happens, the sun's heat has raised such a large amount of vapour during the day as at night to cover every flower and twig first with dew and then with hoar frost? Surely in this case there is more than sufficient moisture to counterbalance evaporation. Besides, how can the juices of the plant be dried up when the surface is covered with moisture? I confess it appears to be more in accordance with observation to say that vegetable life requires a certain amount of heat (varying according to species) to enable it to perform its functions. When our fingers or toes are frost-bitten and drop off, we do not attribute it to evaporation, but rather to suppose that they have lost the heat requisite for the circulation of the vital fluid, and in consequence have become mere dead matter, subject to the usual processes of decomposition, and the same explanation seems applicable to plants. I admit that this does not throw much light upon the actual mode in which cold operates upon plants; but it is probable that among its destructive effects the rupture of the sap vessels may hold a prominent place. Not having microscopically examined the tissues of frozen plants, I merely suggest the idea in the hope that some of your readers may be able, from personal observation, to confirm or negative the supposition. *R. E. E. Gard. Chron., September 23, 1854.*

R.H.S. Award of Merit, August 27. Colour yellow, with red anthers. Shown by F. Kemp, Esq., Hayward's Heath. (see p. 174.)

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Dendrobiums.—Many of the earliest-flowering plants of the tender, semi-deciduous Dendrobiums are now completing their season's growth and are producing terminal leaves singly at the apices of the new pseudo-bulbs. As this stage is reached every encouragement should be given the plants to assist in ripening the growths in order to withstand the dark winter months and produce good flowers in the early spring. It is advisable to examine the specimens frequently, and those that are completing their growth should be placed in a position where more light and air can reach them, preferably at one end of the division where the plants are growing, so that slightly drier conditions may be maintained, although the plants should not suffer from dryness, as the roots are very active just now, and any check received through long periods of dryness will prevent them fully completing their growth, while new growths may appear prematurely from the base. During favourable weather the syringe should be used early in the day to prevent attacks of red spider, etc. As the pseudo-bulbs become well finished and ripened, water should be withheld gradually, and the plants may be removed to cooler and drier quarters and exposed to all available light, being given just sufficient water at long intervals to keep the roots in a healthy condition and prevent the pseudo-bulbs shrivelling. In early spring, when the flower buds are developing, a gradual increase of heat and moisture will be needed to assist in the full development of the flowers. As the growths are nearing completion, many varieties will require staking. Where there is ample room to winter the plants successfully, some species, such as D. Wardianum and D. Pierardii, bloom freely and show to the best advantage if allowed to keep their natural pendant habit. Small scale insects and red spider are often troublesome during the drier, ripening period, and should be removed by careful sponging with a reliable insecticide. Other Dendrobiums that are in various stages of growth should be given every encouragement, allowing so much sun-heat as possible to reach the plants without damage to the foliage, and maintaining a moist and buoyant atmosphere. The afternoon syringings should be lighter and a little earlier than last month, and enough air should be admitted to keep the atmosphere sweet, especially at night, when a little fire-heat may be necessary to maintain the required temperature with ventilation, and also prevent moisture condensing on the foliage, which conditions would quickly induce black spot on the foliage. Seedling Dendrobiums that are still in growth should be kept near the glass in the warmest house and encouraged to make as much growth as possible before the shorter days arrive.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Grease-banding Fruit Trees.—The practice of "banding" fruit trees for trapping the egg-laying Winter and Mottled Umber moths, is now fully recognised by gardeners, and, economically, is most essential in the case of tall garden pyramid and standard trees. But it is not quite so essential in the case of cordons, espaliers, and bush trees, owing to the very high egg-destroying properties of the various forms of tar-distillate washes now on the market. These tar-oils possess a remarkable degree of efficiency in the destruction of insect eggs. They are economical in price, and easy to apply to the trees during the first two months of the year. In the case of small bushes there is very little waste in application, as the spray can be controlled, and directed to any part of the tree. It is not so in the case of lofty trees, for there is always a large amount of waste, as the slightest wind will carry the spray with it, and the sheltered side of the tree is often insufficiently covered by the wash. But gardeners can, by grease-banding these trees, do much to eliminate the possibility of a bad infestation by caterpillars next spring, and provided these bands are kept in a "sticky" condition until the end of April, there is a good chance of destroying the egg-laying March moth, whose caterpillars are equally destructive to foliage, shoots and fruits, and also of catching many Apple-blossom weevils that are on the ascent at that period (March and April). All the insects mentioned are practically wingless (the Apple-blossom weevil excepted, but even so, it prefers to crawl), and are obliged to ascend the trees by crawling up the trunks in order to deposit their eggs near the tips of the branches. The caterpillars of these moths are by far the most destructive pests to fruits in this country, and as each moth is capable of laying some hundreds of eggs, the attack can be very greatly reduced by the use of grease bands. The best time to place the bands in position on the trees is towards the end of September or early in October, as it is at this period that the female moths commence their upward climb, migration going on sometimes until January. The greater number, however, is caught on the bands about the third week in November, but this may vary somewhat according to climatic conditions. Although this sticky composition may be applied to the trunks of aged trees without injuring them, with the very best results, it is preferable to use grease-proof paper bands on which to smear the grease, for the younger trees. Special paper can be obtained for the purpose. It is about five inches wide, and made up in rolls of fifty or one hundred yards each. These paper bands should be placed at a sufficient height (two to five feet) from the soil, to eliminate the risk of their being covered with grit during the winter. The ends should overlap a couple of inches or more to allow for shrinkage, and the bands should be securely tied with string at the top and bottom margins. The composition is then applied very thinly by means of a paddle-shaped piece of wood, choosing a dry, warm day for the operation, as then the composition will be thinner and more workable than on a cold day. A band of grease, a couple of inches or so in width, applied just under the top string is quite sufficient. The grease tends to thin out in warm weather after application. Examine the bands periodically, and should a skin form over the grease, although it should not, pass a toothed paddle-shaped piece of wood over the band, and so expose a fresh surface of the material.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Tritonias.—Tritonia Brilliant and other varieties are worthy of cultivation, especially where a cool-house only is available to produce flowers. The plants increase and flower freely and last in bloom over a longer period than most subjects. The corms should be potted now, placing eight to ten in a forty-eight-sized pot. They will thrive in almost any open soil with coarse grit added. After potting, grow them in a cold frame from which frost is excluded, until such time as their flower spikes appear, when they may be removed to a cool greenhouse for flowering.

Cinerarias.—These plants will now be in various stages of growth and will need attention as regards potting. To obtain sturdy growth, the potting compost for those that are to be placed in their flowering receptacles should consist chiefly of loam, with some grit added to ensure a free passage of water. For those that are to be pricked off into boxes or potted up into small sixty-sized pots, some leaf-mould should be added to the compost. Cinerarias enjoy cool, moist conditions, with an abundance of air, in which to grow; it is a mistake to coddle them at any stage of growth, and the house in which they are grown should be fumigated at intervals or the plants sprayed with an insecticide to keep green fly in check.

Calceolarias.—Plants of herbaceous Calceolarias raised from seeds sown last month should now be ready for transference into small pots. Use a rich, open compost for this potting. Good, open loam, with some dried cow manure or old Mushroom-bed manure and grit added, should form a suitable compost. The plants should be grown under the coolest possible conditions, and they will thrive best where they can be stood on moist ashes, preferably in a cold frame. Young plants of Calceolaria Clibranii may now be potted on; they should make fine specimens for the conservatory next year.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Strawberries in Pots.—Since the Strawberry runners were detached from the parent plants the weather has favoured the application of liberal supplies of water, and those who have watched and noted results know quite well that the best and ripest crowns are secured when bright weather necessitates frequent watering. The earliest potted plants will now be slackening growth and the crowns will be getting plump, but they are not ripe yet and should not be hurried into maturity, as checks from this cause mean loss of tender roots before the beginning of winter. Mild feeding may still be carried out as cutting off the food supplies before growth ceases is a step in the wrong direction. Later, when these plants have filled their pots with healthy roots, they should be plunged in some moisture-preserving material in a light, open pit where water may be given them regularly. Later plants, possibly in larger pots, will make rapid growth for some time to come, and ripe roots being as important as ripe crowns they should be moved occasionally and set a greater distance apart to admit light and fresh air freely among them. Remove all runners, weeds and weak secondary crowns, and give a little weak soot water or liquid manure twice a week.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

The Rock Garden.—The season has arrived when many of the smaller bulbous plants should be planted freely on the rock garden, for they make charming pictures during the early months of spring, if associated with such carpeting plants as Aubrietias, alpine Phloxes and the dwarfer of the mossy Saxifrages. Among the earliest to bloom is Chionodoxa Luciliae, which, with its bright blue, white-eyed flowers, is equally effective naturalised on mossy banks or in sheltered nooks in the rock garden. The Winter Aconite is also welcome during the dull days of early spring, with its golden-yellow blooms. These and the early-flowering Crocuses should be planted at the earliest possible moment to ensure good results the first season. Alpine plants worth noting for continuing the flower display so long as possible into the autumn are the four late Gentians, namely:—Gentiana sino-ornata, G. Farreri, G. asclepiadea and G. septemfida. No plant of this glorious family is so easy to grow or to propagate as the first-named. It soon forms large tufts which are covered during September with erect trumpets of dark blue. It loves cool, rich soil at the base of the rock garden. It is easily propagated by cuttings or division; on examination of the old plants it will be found that most of the young shoots have a plentiful supply of roots attached to them. Incidentally, the blooms last well in water as cut flowers and the shoots will eventually emit roots as the blooms fade. This plant seems to be at home all over the country. G. Farreri also blooms during September, and is the glory of the garden with its Cambridge-blue, white-throated flowers. It is much more difficult to grow in the south than the former species, but is well worth special preparation as regards choice of site and compost. It requires abundant moisture at the roots, but without stagnation. As seen in the north, it is such a glorious plant that all should attempt to find a place congenial to it. G. asclepiadea, commonly known as the Willow Gentian, is also a welcome plant during late August and September for the larger rock garden. Growing from two to three feet high, the arching shoots wreathed with beautiful blue trumpets, are most attractive at this season. It loves a cool, moist position, and is not particular in the matter of soil. G. septemfida and its varieties are accommodating plants, perfectly hardy and easily grown in a moderately moist position in peat and loam.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Carrots.—Where the main crop is showing signs of maturing, lifting may be proceeded with at once, for should a rainy period set in the roots will crack and so be rendered useless for storing. The late roots will be all right for a few weeks yet. Late-sown plants should be thinned; dust plenty of soot around the roots and hoe it in.

Celery.—Continue to earth-up Celery as growth advances. Keep the stalks firm, and work plenty of soil tightly around the plants, but see that no soil is allowed to collect in the centres of the plants. Keep the batches well supplied with water while they are growing freely.

Potatos.—The main crop and late varieties may be lifted as the haulm dies down, as no good purpose will be served by leaving them in the ground. Select a dry day for the work, and allow the Potatos to remain upon the ground to dry for a few hours before collecting them for storing. Grade the tubers as they are lifted. The "seed" tubers should be placed in the open, in the sun, to green them. Turn them once or twice before removing them to the store-room and be sure to label each variety.

Celeriac.—This crop is now growing fast and should be afforded plenty of water at the roots. Soakings with liquid manure should be beneficial; keep the rows free from weeds by hand weeding and with the Dutch hoe.

Vegetable Marrows.—As Marrows attain a fair size and the skins become hard, they should be cut and placed in the store room in which they should keep for a considerable time if ripened, provided the store is dry and airy.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq. Rosemount, Monkton, Ayrshire.

Violets.—These should now be transferred to the frames in which they are to flower. Although they prefer a shady, cool place during the summer, the opposite conditions are required now. The sunniest position possible should be chosen, in well-drained soil, which should be raised to allow the plants to just clear the glass when planted. If the soil is good, the addition of some leaf-soil and sand may be all that is wanted, but no heavy retentive mixture will grow Violets in winter. Lift the plants with great care, retaining large balls of soil, by cutting with the spade on the four sides to the full depth of the roots. Remove any decaying leaves and plant so deeply that the collar of each plant is underground, but the crown exposed, so that roots may be emitted from the whole stock. After planting, a thorough watering should be given and the frames kept closed and matted during the day until growth is re-established which, with ordinary care, should be in a week's time. Thereafter, gradually increase the air supply and, so soon as the plants show no signs of flagging, remove the lights on every favourable day. The lights may be put on during heavy, cold rains, but never closed, even in fairly hard frost a little air should be admitted at the back, with plenty of mats for protection. The distance at which to plant must be regulated by the size and variety; they should not touch or damping-off is sure to take place.

Planting Bulbs, etc.—May-flowering and other Tulips, Spanish and English Irises, St. Brigid Anemones, etc., should now be planted. The soil for these should not be heavily dressed with fresh manure, but should, at the same time, be in good heart and of fine tilth. After thoroughly working the soil, drills four or five inches deep should be made with the spade, in which the bulbs or corms may be placed, surrounding them with a little rough sand if the soil is retentive. Press the bulbs gently into the soil but leave the earth free above; it will become solid enough before spring. If annual lifting is practised, these subjects may be planted fairly closely together—two or three inches apart for Irises and Tulips, and the same or rather more for Anemones, according to the size of the tubers. Being hardy, no protection should be given, even although they appear above ground before winter.

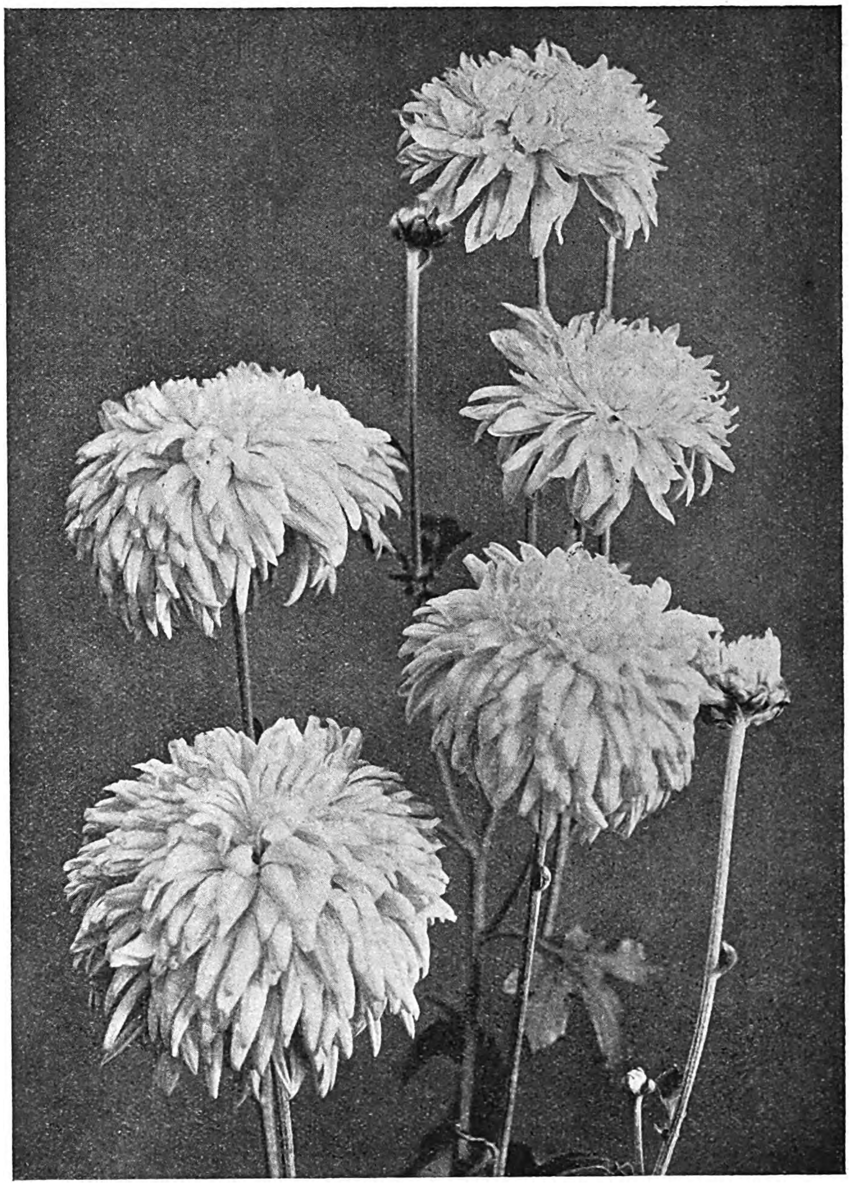

FIG. 108.—CHRYSANTHEMUM KINGCUP.

N.C.S. First-class Certificate, September 9. Flowers yellow. Shown by Mr. W. Shoesmith, Junr.

(see p. 235.)

Rambler Roses.—An early opportunity should be taken to overhaul these. In most cases all the flowered wood should be cut clean away at the base and the newly made growths tied into position; the extra light and air so afforded will help to ripen them and ensure their passing unharmed through the winter. In cases where growth is insufficient to permit of this, one or two of the previous season's growths may be retained, but all flowered or weak portions cut away. Liberal supplies of farmyard manure should be spread around them and pointed in now, or later, as may be most convenient. If red spider or aphis are present, steps should be taken to thoroughly cleanse the retained growths; for mildew or black spot, spray with lime-sulphur.

Housing Plants.—Arrangements should be made for housing all plants at present finishing their growth in the open or in cold frames. As the days shorten, damping is apt to set in among Cyclamens, Primulas, Cinerarias and similar subjects, therefore a cool house should be afforded them, placing them close to the glass. Young plants of perpetual-flowering Carnations should now be housed and staked where necessary. If the pots are well filled with roots a pinch of Carnation manure may still be given, but the application should not be repeated during the dull winter months. From now until spring, water should be given with great care and at no time should saturation be allowed. Red spider, the worst pest of Carnations, should be dealt with so soon as noticed.

Show and Regal Pelargoniums.—Cuttings of these should be rooted in boxes of light, sandy soil, in a close frame, after which the plants to be retained should be pruned back to within a few inches of the bases of the current season's growths, and the plants placed in a close frame. Withhold water from the roots entirely, but syringe them once or twice a day during bright weather.

INDOOR PLANTS.

HIDALGOA WERCKLEI.

This fine climbing plant from Central America has never achieved a great measure of popularity and yet, at the time of its introduction, it appeared to have a great future; known as the Climbing Dahlia, possibly because of the resemblance which its flowers bear to those of the popular single forms of the Dahlia, H. Wercklei is a quick-growing greenhouse herbaceous climber, attaining twenty feet or more. Its flowers are bright scarlet above, yellow beneath, and while they certainly recall those of Dahlias, they lack the symmetry and regularity of outline inseparable from those flowers. The leaves are much divided and very elegant, and the plant climbs by means of long, twining petioles.

The plant is fibrous-rooted and thrives in a light, well-drained soil; it is effective and valuable in the cool greenhouse, and plants secured by early propagation should prove of service in the summer flower garden, for the growth is rapid and the plant is exceedingly free-flowering, its floriferousness ceasing only with the advent of short days and cold weather. A few plants placed in a sheltered position, the foot of a warm wall for preference, should render a good account of themselves; the plant is easily propagated from cuttings.

H. Wercklei, which belongs to the Natural Order Compositae and is closely allied to Dahlia and Coreopsis, was discovered in Costa Rica, in the uplands of that country, by Mr. Carlo Werckle, in 1898, and shortly afterwards a specimen flowered at Kew, where it created a favourable impression.

TACCA CRISTATA.

This singular plant, which is sometimes described under the name of Ataccia cristata, is seldom grown, but occasionally, at Chelsea and elsewhere, it is a centre of interest by reason of its remarkable appearance. The thick and coarse root-fibres proceed from a stout and short root-stock, and from this root-stock issue the five or six leaves, with smooth petioles but a few inches in length; the oblong-acuminate blade is dark green and prominently veined, and in a vigorous plant may be some eighteen inches long. The scape rises above the leaves, erect and smooth, and terminated by a prominent, four-leaved, membraneous involucre, the two outer leaflets opposite, the two inner placed side by side, erect, large, semi-transparent, and of chocolate colouring. The peduncles are numerous, each bearing a solitary flower, the whole forming a drooping umbel; in addition to the floral peduncles a number of sterile ones are produced, long, pendulous and of tendril-like form, chocolate, or a shade of brown approaching to it, being the prevailing colour of the whole.

Indigenous to Malacca, this weird, almost insect-like plant is found growing in moist situations, so that heat and moisture are very necessary to it when under cultivation; a stagnant or saturated condition of the compost is, however, fatal to its well-being. A suitable compost is formed of fibrous-peat or Osmund fibre shredded rather finely, small, broken crocks and sharp sand. Light shade should be provided during the summer, and a moist atmosphere maintained by the free use of the syringe; during winter, the supply of water will require modification, but the compost should never be allowed to become really dry. The flower-scapes are usually produced in spring, but will occasionally appear at other seasons of the year.

Propagation of this quaint plant is effected by separation of the side-growths which are produced from the main stem; the plant is not, however, unduly prolific of these shoots.

T. cristata was introduced from the Malaya in 1812; it is figured in *Bot. Mag.*, t. 4,589, under the name of Ataccia cristata. Some growers incorporate a little loam in their compost for this plant, but it appears happier in peat or fibre. *Ralph E. Arnold.*

HARDY FERNERY.

CHEILANTHES GRACILLIMA.

The genus Cheilanthes belongs to the family Polypodiaceae. It contains over one hundred species, mostly xerophytic, which inhabit the Tropics, and the northern and southern Temperate Zones. It is allied to Adiantum, Gymnogramma, Pteris, and the ubiquitous Bracken (Pteridium aquilinum). Cheilanthes gracillima itself is a native of north-western United States, and California, where it grows in fibrous, gritty soil among rocks at about 12,000 feet above sea-level. It was first recorded in 1859.

It forms small rosettes or hummocks surmounted by almost triangular, bipinnate fronds, one to four inches long, borne on shining, dark brown stalks, which are approximately of the same length. The pinnules are small, dark green and coriaceous; when first unfolded they are covered with greyish down.

In common with many xerophytes, the leaf margins are recurved so strongly that they almost meet in the middle line beneath. The groove thus formed is filled with a soft, fulvous pubescence. This is to protect the stomata—which are chiefly on the under-surface—from over-rapid transpiration in the drought which xerophytes have to endure. The same character may be noticed in Empetraceae, Ericaceae, Rosmarinus, etc.

This little Fern is quite hardy, and is stated to withstand so much as 60° of frost, with a snow covering. It is an especially suitable plant for the rock garden, where its dainty rosettes will line the crevices of a bold rock-face in full sun, amply accounting for the well-earned name of Lace Fern. *Graham S. Thomas, University Botanic Garden, Cambridge.*

HARDY FLOWER BORDER.

EUPATORIUM PURPUREUM.

Joe Pye Weed is the vernacular name for this species throughout its native habitat—North America. It is a rather coarse-growing plant, sometimes attaining a height of eight or nine feet, and is usually found on low ground or in woods or thickets. The large, flat-topped inflorescences, purplish-pink in hue, make bold splashes of colour on the early fall landscape, and contrast charmingly with the bright yellows of the Solidagos, which grow in profusion in association with it.

While not refined enough in appearance to merit a position in the small herbaceous border, it is a valuable subject for massing against shrubs in the wild garden, or for planting near the waterside. It might also be used with due discrimination in a large herbaceous border. The simple stems bear oblong-ovate or lanceolate leaves, in whorls of from three to six. The leaves are thin in texture, smoothish, and rather finely crenate-dentate.

Eupatorium purpureum is naturally variable and several distinct varieties have been described. According to Gray, variety maculatum is "more pubescent, with thicker and more rugose-ovate to ovate-oblong incisely and coarsely toothed leaves and flattish-topped cymose panicles of more crowded rose-purple or paler heads." It usually occurs in wetter places. Variety amoenum is "low; leaves fewer, often opposite, ovate or oblong, heads few"; variety foliosum "leaves thin, elongate, the upper much overtopping the compact flat-topped inflorescence"; and variety augustifolium, "seems to be only a weak form or state" of the type plant. *T. H. E.*

CLEMATIS INTEGRIFOLIA.

In 1596, this plant was brought into cultivation from eastern Europe. Unfortunately, although having had a long period in which to become widely grown, and in spite of being a plant of unusual beauty, long-flowering period, and easy culture, it is still uncommon—a fact perhaps traceable to the rather slow facilities of its propagation, of which seeds afford the best method. It resents disturbance and division. In common with other Clematids, it has no true petals, their place being taken by coloured sepals (as in Caltha, and other members of Ranunculaceae, to which family the subject of this note also belongs), and the flowers contain no honey.

This Clematis is a herbaceous plant, forming a clump of rigid, softly pubescent stems about two feet in height, most of which, on a well-grown plant, will bear flowers. The leaves are smooth, oppositely disposed, entire, ovate-lanceolate, and of rather dull green, about three inches long and half as wide. The upper pair of leaves is concave and encloses the terminal bud in its younger stages. From this last pair of leaves the stem proceeds for six inches or so, then arches gracefully, bearing a long, pointed, pubescent bud, which unfolds in due course and becomes a great nodding, four-sepalled flower of softest bluish-violet, with a cluster of pale cream stamens to enhance its beauty. When the flower first opens, the margins of the deeply-veined, coriaceous sepals, which are from two to three inches long, are edged with short, white pubescence; this, later on, disappears, and the margins become wavy. Also, the sepals twist with age, giving a delightful effect reminiscent of the similar, although considerably smaller, flowers of the climbing C. Viticella. Besides the terminal flower there are two or more flowers which develop later, completing the inflorescence—a cyme—and prolonging the flowering period from June to the end of August.

The fruit is a group of achenes, upon which remain the styles; they become silky-haired, and curl over with an elegant, mop-head effect. This both gives greater beauty and tends to secure wider seed distribution.

Of varieties there are few; one with pinnate leaves—merely a curiosity—and one with larger flowers.

In cultivation, this beautiful Clematis is easy; all that it requires is a good, deep, loam, and not too hot an exposure. It is equally effective for the front of borders or for the back of the rock garden. It also gives continued pleasure if a bed is devoted solely to it. *G. S. T.*

BULB GARDEN.

NARCISSUS MINOR.

There are signs that the use of bulbous plants in the rock garden is becoming much more general, and the special value of early flowers of this class is being more and more recognised. Among the most pleasing and attractive of these are the miniature Daffodils, which really call for a position in the rock garden to enable them to reveal their beauty to the utmost. In a recent issue of the *Journal* of the Royal Horticultural Society there was published a valuable paper by Mr. P. R. Barr, in which he discussed the smaller Narcissi suitable for rockwork. In this the value of Narcissus minor was referred to along with others, and in my rock garden this species always forms a delightful little group. This Daffodil is rather difficult to obtain true, as is the true N. nanus, which is even smaller than N. minor, and comes in between it and N. minimus.

N. minor is exceedingly beautiful in its own way. The general form is that of N. maximus. It is only about six inches in height, and has flowers of a fine yellow, the trumpet being prettily flanged at the mouth and the perianth twisted in a most charming way. This Daffodil is exceedingly attractive also when grown in pots or pans for the alpine house. Unfortunately, the true N. minor is now scarce, and its price puts it beyond the reach of a good many for planting the large groups in which it looks best, but a seedling from it is in commerce and is very little more than a fifth of the price, while it comes so near the true N. minor that it will satisfy many, especially as it is very beautiful and can withstand comparison with its parent, N. minor. There are, however, a few differences. It is slightly taller, and the perianth is less elegantly twisted, although the trumpet is nicely flanged. The flowers are also rather lighter in colour. It has no name that I am aware of, but that of N. minor seedling.

These two miniature Daffodils flourish in the ordinary soil afforded to rock plants in general, and are much the better for being carpeted by some dwarf plant, such as Veronica repens. A plant not usually frequented by slugs is desirable, as these pests may injure the flowers and deface their beauty. *S. Arnott.*

ALPINE GARDEN.

GYPSOPHILA REPENS.

THE genus Gypsophila has given us several plants which are now indispensable for the rock garden, and among these is Gypsophila repens (Fig. 109), a low-growing, mat-forming and practically indestructible plant. It is ideal for draping rocks and is, therefore, extremely useful for furnishing rock walls.

Gypsophila repens is common throughout the Alps. It forms a close mat or mound—according to its position—of interlacing, slender growths, clothed with glaucous, narrow foliage, and throughout the summer maintains a steady profusion of delicate sprays of blossom, white in the type but ranging to rose-coloured, this latter sometimes being given varietal rank—G. repens var. rosea.

There is also a monstrous variety of this dainty carpet plant, *i.e.*, G. repens var. monstrosa, which is much coarser in growth and produces masses of large sprays of white blooms one foot or more high; it is a hybrid of G. repens and G. Stevenii, and is well worth securing.

No trouble should be experienced in the culture of these Gypsophilas, as they are easily increased. *F.*

DEINANTHE COERULEA.

A NATIVE of China, this very beautiful member of the family Saxifragaceae is a most desirable plant. It has proved to be perfectly hardy at Cambridge, surviving the severe weather of last winter without protective covering.

It is herbaceous, and has a stout, horizontal root-stock; the leaves, four in number, are opposite and form a whorl-like cluster at the top of foot-high stems, and have reddish-pink petioles an inch or more long. The broadly-ovate or elliptic leaves measure six or more inches long by four-and-a-half inches wide, are rugose and strigose, with the margins coarsely serrate.

The blooms, produced during July and August, are borne in terminal panicles rising above the foliage on two-inch-long peduncles, carrying from four to seven charming, nodding, blue flowers, having numerous stamens of the same colour, each flower being an inch-and-a-half across. Both fertile and sterile flowers are produced; the sterile are not so numerous, are only half-an-inch across, and spring singly from the pedicels of fertile flowers; these are also blue in colour, fading to a greenish hue with age. This species flowered for the first time in England in 1909.

Deinanthe coerulea does well in this garden in a somewhat moist and shady part of the rock garden. *J. Blades, University Botanic Garden, Cambridge.*

HIERACIUM BOMBYCINUM.

THE Hawkweeds do not enjoy a reputation so exempt from ill-fame that one would admit them to the garden without suspicion. But the subject of this note is a plant of such charm and of a habit so pleasing that Mr. Ingwersen, who persuaded me to try it, was prepared to stake his good name on its quality and behaviour.

H. bombycinum is a Spanish species with grey-green, spoon-shaped leaves three or four inches long, and covered on both sides with silvery hairs. This woolliness suggested trouble in our humid winters, but H. bombycinum has come through not only excessively wet seasons but proved itself capable of resisting 30° of frost. The leafy tuft is not more than three or four inches in height and the plant, unlike so many of its kind, grows in a firm, compact clump. The flowers, borne on very silky, branching stalks some eight inches tall, are about as large as a florin, and of a particularly bright yellow which goes remarkably well with the silvery foliage. A succession of these cheerful blooms is maintained throughout the later spring and early summer. Seeds are produced abundantly, and the large, round "clocks" of iridescent down which accompany the ripening stage are distinctly ornamental. These, moreover, are so resistant to wind and weather that one may forget about them for a week and still find them intact, conveniently awaiting the seed envelope. H. bombycinum is a lover of sun, and I have yet to find a place too hot and dry for it. It is one of the few plants here which have thoroughly enjoyed one of the driest and most trying seasons we have had for many years. *N. Wales.*

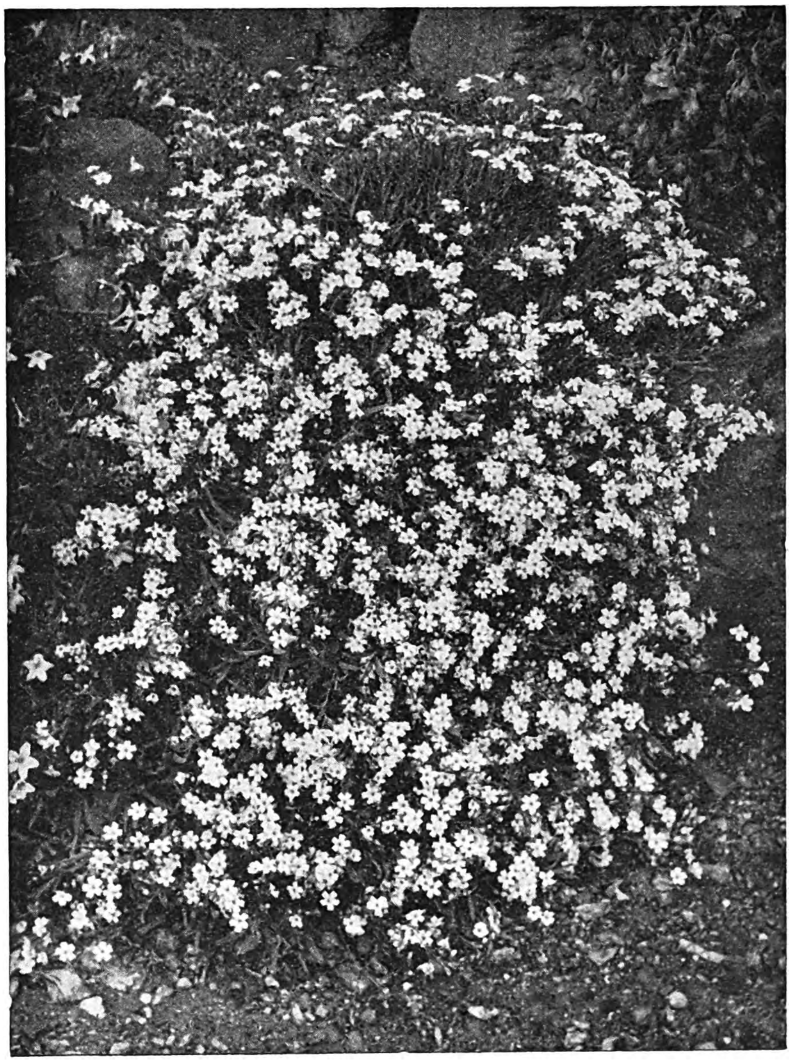

FIG. 109.—GYPSOPHILA REPENS.

TREES AND SHRUBS.

CISTUS RECOGNITUS.

ACCORDING to the Kew *Hand List* and other authorities, the legitimate owner of the above name is a C. laurifolius × C. monspeliensis hybrid which is also known as C. glaucus. I cannot recall ever having seen this plant, but Mr. Bean tells us (*Trees and Shrubs Hardy in the British Isles*) that it closely resembles C. Loretii but for its broader leaves and unspotted flowers. The C. recognitus of gardens with which I am dealing here is a very different shrub, and one of such superlative merit that there seems more than a probability of its retaining the name it bears for an indefinite period. At any rate, it is likely to do so until it is given another. What this C. recognitus is, and whence it came, still appear to be unsolved problems. That it is close to C. Loretii (a C. ladaniferus × C. monspeliensis hybrid) will be conceded by all who know it, and it may possibly have had a similar origin. But it is, nevertheless, so distinct that no grower of Cistuses could even confuse it with C. Loretii, or, for that matter, with any other Cistus in cultivation.

C. recognitus, to use its adopted name, differs from C. Loretii in growing nearly twice as tall and having a stiffer, more woody habit. Its lance-shaped leaves are narrower, more pointed and more deeply waved at the edges than those of the better-known hybrid. They are also much more gummy, and during mild, moist weather, especially in spring and autumn, emit a most delicious aromatic fragrance suggesting "Lemon Verbena," a scent which I have not detected in any other Cistus. These leaves are a light rich green with pale undersides, and they are practically hairless. The well-rounded flowers, which are borne in amazing profusion, are nearly three inches across and pure white, with a rose-carmine blotch at the base of each broad, overlapping petal. This blotch is rather smaller than that of C. Loretii, but it is of a keener, more vivid hue than that of the other shrub, the pencilling is more marked, and the zone of yellow which surrounds the stamens is broad and unusually conspicuous.

C. recognitus was among the few Cistuses which survived last winter here, which means that it is one of the hardiest of its race. I find it, moreover, one of the most adaptable and easy. It can be propagated from cuttings without the slightest difficulty, and is such a fast grower that one may often have cuttings flowering in their second year. These will be fully-grown shrubs in about four seasons, and the only trouble likely to occur with them is the possibility of their dying or being rendered useless by over-flowering. I should have no hesitation in giving this Cistus a place among the "best six" Rock Roses for general garden culture. *A. T. J.*

CEANOTHUS BURKWOODII.

THIS remarkable introduction will afford all those who delight in its charming race a thrill of fresh interest, since it gives us a Ceanothus which is entirely new in nature and appearance.

Those specialists in hybridisation, Messrs. Burkwood and Skipwith, of Kingston-on-Thames, who have added the creation of this shrub to their other achievements, do not divulge its origin, but one may conclude that the plant is the result of crossing an evergreen Ceanothus with one of the later flowering deciduous species. At any rate, we have in this hybrid an evergreen Ceanothus which, while it has all the beauty and fascination of the spring flowering species, flowers through the late summer and right on into autumn. That in itself bears its own significance, but C. Burkwoodii goes further, inasmuch as its panicles of blossom are considerably larger than those of most of the evergreen species, and in colour they are a rich indigo-blue. The ovate, sharply-toothed, alternate leaves are about an inch long. They are a rich, glossy green and smooth on the upper side, the under parts being silvered with a fine down. Although my specimen of this excellent novelty is only some two to three feet tall, it has flowered abundantly. Last winter it withstood 32° of frost without protection, and from this I am inclined to think that it will prove hardier than most of the evergreen species. *J.*

SOME ROCK GARDEN VIOLAS.

THE time being ripe for the planting of rock garden Violas, mention of one or two well-tried favourites may be useful reading to some. Perhaps V. calcarata might be accorded a foremost place in a small selection containing nothing very rare or difficult, for in any good form it is a most desirable plant. No Viola species of my acquaintance, save, perhaps, V. cornuta, flowers so profusely over so long a period as this Alpine Pansy. That it is not always as tractable as a "Maggie Mott" one readily admits, but, after all, that uncertainty which, so one may presume, accounts for its comparative rarity in gardens, flavours its culture with a wholesome spice of interest. What V. calcarata needs in the way of treatment I dare not suggest, but it is an all-season flower here under conditions which provide anything but the rich soil and abundance of water recommended by Farrer. The heartiest plants I have ever had have occupied a bed of poor, dry, sharply-drained loam, mostly stones and grit.

Another singularly prolific flowering Viola is V. cucullata var. alba. This does very much better here than the type, making big, lusty clumps of its downy, heart-shaped leaves and producing for several months in spring and early summer an amazing crop of blossoms. These flowers are usually well over half-an-inch across, of good shape and texture and a firm creamy-white. This plant will seed true to colour, and it is of the easiest culture in any fairly cool, partly-shaded corner. Under similar conditions, giving it the consideration its small size and extreme daintiness deserve, V. biflora will always prosper satisfactorily. This charming little plant, a true alpine, is indeed a subject for associating with the choicest gems of the rock garden. Its pale-green, kidney-shaped leaves are comparatively few and occupy but little space, for it spreads but slowly, and its twin flowers are so tiny that a close-up position is essential if their charms are to be fully appreciated. These blossoms are a rich butter-yellow, clearly rayed with dark lines, and the whole plant seldom exceeds three inches in height.

Many of the V. gracilis section (pretty mongrels some of them) are so wanting in quality that they would probably not survive a season but for the borrowed radiance shed upon them by the name of the species. Even so, it does not do to be too exacting over these until one is fairly satisfied as to what the type should be like, and on that point opinions differ widely. Rightly or wrongly, I cling to the faith that a small, rather frail plant, with leaves almost grass-like in their narrowness, is the genuine Slender Pansy of Macedonia and Asia Minor. This shy little thing has reduced its deep violet petals to mere strips, and these have accentuated the sylph-like grace of the flower by indulging in Cyclamen "tweaks" of the rarest refinement. At the other end of the scale is a plant called V. gracilis var. major. I believe this came here from the generous owner of Aldenham House, and it is one which, while it retains the true "gracilis" character, bears flowers of such large size that they could not possibly be mistaken for those of any other form. A really typical white V. gracilis has yet to be introduced. It seems odd that we have not already had it, but the lucky discoverer of such a plant will certainly enjoy a great reward.

For our own V. lutea I have an affection that will not be shaken by the appeals of any other rock garden Viola. A rich yellow, brown-rayed form found, not in the limestone which yields the tri-coloured Mountain Pansies, but on our western granite, is especially delightful. Although it threads its long, slender runners through the dense grass of upland moors, this little charmer will, under cultivation, make a tidy, self-contained pad of its delicate green, and cover it for the greater part of summer with blossoms which have all the elegance of line and poise of V. gracilis itself. Sir Herbert Maxwell, writing in these columns recently, reminded us of the fact that many of our native plants, although they may seem unruly, straggling things in the tangle of the wild, prove to be most exemplary garden subjects. V. lutea is one of these and all the Alps do not yield a better rock garden Viola.

Those whose tastes lean towards fatter fare and yet desire to avoid the hybrid bedder, will find satisfaction in V. rothomagensis. This, the Rouen Violet, grows in a neat and restrained tuft, and yields all the season through a crowd of podgy, round-faced, lavender Pansies. In many gardens this amiable species will produce its own seedlings in quantity and with a remarkable regard for family traditions. V. canina var. clatior which, writing from memory, is a discovery of Mr. Clarence Elliott's, is a good plant for a shady corner. At any rate, it has always been grown in this garden in a cool, sunless place among dwarf Ferns and kindred things. There it raises its twelve-inch stems and displays the pale, cold purity of its luminous bluish-lavender blossoms to better advantage than in a fuller light. Similar treatment, with, perhaps, a little more sun, also suits that mysterious little treasure, the St. Helena Violet, the delicacy of whose colouring equals that of the gentle Bog Violet (V. palustris). This old but always uncommon Violet is, moreover, endowed with a fragrance of rarest refinement. V. canadensis, being a woodland species, will also enjoy a rather cool position. It is a robust plant with heart-shaped, serrated leaves and big, starch-white blooms with a yellow eye set in a stain of purple. V. c. var. Rydbergii, which I have seen but once or twice and never been able to acquire, is a still finer plant.

As for V. odorata, a place which is not too hot nor yet too rich—for the plant gets gross by too good a living—must always be found for the yellow form usually listed as V. sulphurea. Indeed, there would seem to be more than one of these yellow Sweet Violets, but my own favourite is a soft nankeen, the flowers being small. This plant, although it flowers profusely, is never lush and pushful in a poor soil. V. hirta is another native which is worthy of wider recognition, and here again is a species which can be relied upon to remain in such a neat little tuft that it may be placed with the choicest plants without suspicion. V. hirta, moreover, can do with drier, more sun-beaten places than most. Its narrow, heart-shaped leaves are pale green and downy and the flowers, which stand well above them in April, are much the same colour as those of V. odorata. These, however, are scentless, or nearly so, and apt to vary considerably in colour. V. calcarea, given specific rank by some botanists, appears to be a very dwarfed form of V. hirta found on some of our limestone hills. Although V. hirta extends far into the north, I have seen it in splendid feather, with very large flowers, in southern Europe.

V. hederacea, the New Holland Violet, once known as Erpetion reniforme, is a frail and delicate little species which I once had doing well for some years in a cool, rather moist but sunny spot. Delicate it may not be in constitution, nor particularly touchy in temper, but V. hederacea deserves the adjective on account of the singularly dainty, almost chaste, appearance of its elegant little purple Violets. These, with their petals often tipped with white, stand an inch or so above the close mat of vivid kidney-shaped leaves, and a well-grown plant will produce an amazing crop throughout the greater part of summer. Seedlings are often produced in plenty, and some of these potted up in autumn enable one to leave the parent plant to the chances of winter with an easier conscience. *N. Wales.*

THE SMALLER LAND-OWNER AND TREE PLANTING.

THE majority of civilised countries are now anxiously concerning themselves with the position they occupy as regards supplies of timber, and the areas of forest land still left in the hands of the State. The process of forest destruction has been going on for many centuries in the older countries of the world, and in some cases woods have practically vanished, and nothing remains but a few scattered trees or clumps, and an occasional remnant of native forest which has escaped destruction through accidental causes or inaccessibility. In the newer countries, of which North America is a prominent example, the same process is going on, but sufficient time has not yet elapsed for the full effect to be seen. During a period of less than two hundred years, however, the United States have managed to dispose of about 300,000,000 acres of forest, and Canada is following in the same direction. Allowing for the increase in population and the development of agricultural activities, the rate at which the virgin forests of the world are disappearing is about ten times faster than that which occurred in the older countries of Europe during the middle ages, when methods of exploitation were of a more primitive nature, and the need for intensive cultivation of land very much less.

There is little doubt that the maintenance of forest and woodland has been rendered difficult in most countries by the various methods of land disposal which have gradually resulted in the individual taking the place of the State as owner. The feudal system started this process in England and many parts of Europe, and during the course of centuries the tendency has always been towards the division of large blocks of State land into privately-owned or controlled estates, until little remains in direct State ownership. This process is going on with extraordinary rapidity in many parts of Canada, Australia and other British possessions, with the result that various forest areas possessing great potential wealth are being surrendered or leased to private individuals at almost nominal prices, the timber being frequently burned or destroyed without reference to its present or future value, the one thought only being to get it cleared off the ground. The example of the United States in connection with the change from state to private ownership is being rapidly followed in all parts of the temperate zones. In 1850 almost all the forest land in the States was publicly owned. At the present time twenty per cent. only remains in State forest reserves, and many of these constitute merely the poorest and most inaccessible areas which have not been worth the private speculator looking at too closely. This is merely an example of what is taking place in most new countries with regard to public forest lands.

In the British Isles we are faced to-day with a new factor which is making itself rapidly felt in connection, not only with woodlands, but with hedgerow trees which have hitherto changed a bare, and in many ways uninteresting, country into one of great beauty, and which presented many attractions to the visitor from abroad. Not more than half-a-century ago the greater part of rural Britain consisted of estates varying from possibly 5,000 to 10,000 acres or more in extent, and which were nominally under the control of one individual landowner. Every part of an average estate was studded with small woods, belts, and hedgerow trees which were the exclusive property of the landlord, and the latter was usually an individual who took an interest in the appearance, not merely of his estate, but of the country at large. Whatever disadvantages attached to hedgerow trees in general, and however much they may have been objected to by the farming community, there is no doubt that they formed, and in many cases still form, an essential feature of rural England. But on the breaking up of estates which is proceeding with increasing rapidity, numerous farms become separate freeholds owned by individuals who, possibly from necessity, but in the majority of cases from inclination, proceed at once to cut down the majority of the timber trees existing at the time of the transfer. This act in itself may in some cases be desirable on economic grounds, and may not be sufficiently practised to alter at once the general appearance of the country. But the serious feature is the fact that no steps are being taken to replace trees which disappear through felling or natural decay, and this neglect will undoubtedly lead to an entire change in the appearance of many districts which have hitherto been regarded as typical examples of picturesque landscapes.

In the older methods of dividing land into fields, or enclosing it against highways and open spaces, banks and hedges were usually the means adopted. This form of fence doubtless took up a good deal of space, and when time and labour were considered, was particularly costly. There is no doubt, however, that the old hedgerows acted as nurseries for indigenous timber trees, and the majority of Oak, Ash, Elm, Sycamore and other species which constitute the bulk of our hedgerow timber owe their existence to this particular form of fence, and whatever felling occurred was, sooner or later, replaced by seedlings or suckers. In these days posts and wire fences are invariably erected whenever a piece of ground is divided or fenced in, and the hedgerow tree does not come into existence. This change alone will be responsible, in the long run, for millions of trees being lost to the country-side.

Coming to the small wood of twenty, thirty or fifty acres, as the case may be, which the larger landlord made a special point of creating and preserving over his estate generally, we find a similar change is taking place. These woods, as part of the one estate, could be protected and managed in conjunction with many other branches of estate work under the control of one or two estate officials, such as the forester, bailiff, or steward. The splitting up of an estate frequently leaves these smaller woods isolated, and the estate owner finds it impossible to retain them without considerable expense and inconvenience. The usual remedy is either to sell them to the adjoining tenant or when, as is frequently the case, this tenant is not in a position to purchase them at anything like their market value, the timber is sold and the land thrown in to the adjoining farm at a nominal price.

The disappearance of hedgerow trees and small woods, therefore, appears to be inevitable over large areas of rural England, Ireland, and parts of Scotland and Wales, with the breaking up of large estates, and there does not appear to be any power or inclination on the part of the public authorities to find an effective remedy. In Great Britain the Forestry Act of 1919 brought into existence the Forestry Commission, with a view to creating an additional area of forest to the extent of nearly 2,000,000 acres. The object in view was not, of course, connected in any way with landscape or aesthetic considerations, but had for its motive the creation of a timber reserves which could be utilised in national emergencies, such as those brought about by the European war. Associated with this function, the Commission was empowered to assist private owners to plant or replant bare ground or cleared woodland, but it possesses no power to control private woods or to maintain the timbered area of the country in general, except through its own activities. Great Britain possesses, approximately, 3,000,000 acres of privately owned woodland, and assuming that the Forestry Commission's operations will ultimately lead to the creation of an additional area of 1,000,000 acres, and that no change takes place in the private ownership of the remainder, it is evident that seventy-five per cent. of forest will still remain privately owned throughout the country. At the present time, of course, the percentage is much higher.

What, may we ask, is happening to these 3,000,000 acres ? During the European war something like half-a-million acres were felled, or heavily thinned, partly owing to the national necessity which arose, and partly to the high prices which tempted every owner of timber to convert it into cash. During the ten-year interval which has elapsed since that time it would not appear that more than 50,000 acres have been planted or replanted by private owners in spite of the aid of grants and less attractive forms of assistance. This represents, if our assumption is correct, only ten per cent. of the cleared and thinned areas. This would indicate that private woodlands are not being maintained in anything like the desired proportion, as against the activity of the Forestry Commission we must set the apathy of the private owner before the net result can be seen.

It may be asserted that woodland preservation is a matter concerning the economist rather than the socialist or artist. This view, however, is open to question. The amenities of a civilised country cannot be secured and preserved on purely economic principles. If the numerous activities in which the Governments of the day concern themselves are taken into account, it can easily be seen that comparatively few of them have anything to do with economics or, at any rate, to an indirect extent only. By far the greater proportion of them are socialistic, and aim in theory, if not in practice, at rendering the life of the average individual easier, safer, and more pleasant. Is there no place for a picturesque landscape in the life of the community to-day ? We are provided with parks and open spaces to an extent which was never dreamed of half-a-century ago, and the cost of these, in the aggregate, amounts to many millions of money if their capital value is taken into account, but, however attractive they may be they do not take the place of, or afford an adequate substitute for, natural scenery, and natural scenery without timber trees and woodlands does not seem to be worthy of the name unless in regions where mountains are sufficiently massive to dwarf the average features of the country-side, and provide adequate relief in themselves.

The only attempt hitherto made to deal with the preservation of privately-owned timber by Government control is that recently made by the Irish Free State. The conditions in this country as regards land tenancy differ materially from those in Great Britain. In the Irish Free State all agricultural land in the occupation of tenants has been nominally acquired by the State, to whom the tenant pays his annuities in lieu of rents, and ultimately becomes the owner in fee of the holding. Practically all timber standing on these holdings was acquired from the landlord without any payment being made and became the tenants' property on the date of the transfer. Since the passing of the earlier land acts vast quantities of this timber have been felled, and little or no provision made for replacing it.

With a view to preserving such timber as still remains, the Free State Forestry Act, 1928, was passed. This measure met with some opposition, but with a still greater measure of approval, and no suggestion was made which could be considered an adequate alternative to the provisions of this Act. The chief and most important of these provisions is the compulsory notification of felling operations on all landed property, and the power conferred upon the Minister for Agriculture to prohibit these fellings when it is considered necessary. Most of the loss in ornamental timber throughout the Irish Free State is due to indifference on the part of small occupiers, and although compulsory notification will not necessarily prevent trees from being cut, it is hoped that it will check a great deal of unpremeditated and indiscriminate damage to the existing stocks of timber still remaining in the country. It has been contended that an owner should do what he likes with his property, but a great deal of this particular asset has been acquired by means of public funds, and passed on to the tenant purchaser of holdings without any charge. It is only reasonable, therefore, that the Government should possess the power to check its destruction until it has fulfilled its natural purpose, namely, the ornament and shelter of the district in which it stands. Wind and decay will remove this timber in course of time, and this cannot be avoided, but the labour of a past generation should not be sacrificed entirely, and the object of the Act is to prevent this taking place.

How far it will achieve its object remains to be seen, and it will be interesting to compare the results following this Act, and those due to the unrestricted ownership possessed by the individual landowner in Great Britain. The examples of many parts of Spain, Portugal and Italy illustrate what can be done in the way of denuding the country-side of its tree growth. Is there sufficient public spirit in the new landowners of the country to prevent a similar process going on in the British Isles ? If not, what is the remedy ?

A State Forestry Department cannot operate on a small scale. Administrative difficulties prevent areas being dealt with of a corresponding size to the average estate wood, while hedgerow timber is absolutely out of the question as a form of State property. From an economic point of view, the creation of large State forests on inferior types of land may be the soundest objective to aim at, but these State forests alone will not maintain the present appearance of rural England, or the British Isles in general, and it is doubtful if the private landowner will, or can, continue to plant or preserve trees in future in the manner customary on the average estate of fifty years or so ago. The whole problem is surrounded with difficulties, and it remains to be seen whether the Irish Free State has discovered a possible solution, or is making a futile attempt to check the inevitable course of events. *A. C. Forbes, Bray.*

BOG AND WATER GARDEN.

PRIMULA FLORINDAE.

The more one sees of Primula Florindae under different conditions of soil and exposure, the more does one expect of its future, and its possibilities as one of the parents of late-flowering hybrid Primulas are holding out vistas of the gardens of a few years to come, adorned with flowers of other colours, on plants as vigorous and as easily grown as P. Florindae itself.

The day before I read in your issue of August 24 the twenty-eighth instalment of Captain Kingdon Ward's intensely interesting account of his "Tenth Expedition in Asia," I had been examining the vast stock of hardy Primulas at Moniaive, and had said to Mr. J. Adamson that the time would come when P. Florindae and its hybrids might be as valuable in the late summer and autumn garden as the Polyanthus in spring. It was, therefore, most pleasing to observe that Captain Kingdon Ward, in telling of the discovery of a "Sikkimensis" with maroon-crimson flowers, which he describes on page 150, goes on to remark : "and if extremes mate, and it can be persuaded to infuse some of its breeding and sanguine complexion into P. Florindae, the resulting mulattos should be worth while."

There are some who do not care for P. Florindae, which they consider less graceful than P. sikkimensis, but when we remember its later flowering and its wonderful constitution, the prospect of hybrids of various colours is most alluring. There are a few hybrids in cultivation, but not yet in commerce, and if we can have new colours among these it would be a boon indeed. *S. Arnott.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AN ENGLISH GARDENER IN CHILI.

(*Continued from p.* 185).

REPRESENTING Iridaceae are several species of Sisyrinchium (Figs. 110 and 111), the best being a graceful plant (probably S. roseum), in which umbels of pink flowers appear to arise from the side of the stem, in the same way as in most Juncus species, the continuation of the stem serving as sheath for the young blooms. The individual flowers, although not large, are pretty; the golden stamens project outwards, while the petals are frequently reflexed. This species is carried over the drought by the fleshy roots that radiate from the crown of the plant in a similar manner to those of the garden Ranunculus; it also seeds freely.

One of the most striking plants met with in Chili is the "Cardon," or Puya chilensis. The local name appears to be derived from "Cardo," a Thistle, probably owing to its horrible, hooked spines, which, incidentally, are curious in that those at the tips of the leaves point upwards, while those towards the centre of the rosette point down; however, it is far more majestic than any Thistle, as its huge inflorescences tower above the surrounding vegetation. The plant is typical of its family, Bromeliaceae, possessing the long, arching, linear leaves arranged in the form of a closely-packed rosette, and generally a large number of rosettes combine to form a formidable clump which may cover anything up to ten square yards, the leaves reaching four feet to six feet high. From a plant of these proportions one would expect a large inflorescence, and Puya, in this respect, is no disappointment; the spike frequently reaches ten feet high, and the actual inflorescence covers from two to three feet, and is so much as a foot wide. It branches freely and horizontally from the main axis, the large, bell-shaped flowers being borne on the bases of these branches, the tips being barren. The individual flowers are beautifully symmetrical and wax-like, of a greenish-yellow colour, and approximately three inches in length by two-and-a-half inches across the mouth from petal to petal. They afford an interesting example of pollenation by birds, and Dr. Friedrich Johow, in his *Estudios de Biolojia Vegetal,* published in Santiago in 1910, states that in places where the plant is abundant it is difficult to find in spring, a "Tordo" (a small black bird) which does not show in front of his head a large mantle of the most beautiful golden colour; certain it is these birds may frequently be seen resting on the sterile branches and busily sucking the nectar. It is equally certain that the agent of pollenation, be it bird, insect or wind, does its work effectively, for millions of seeds are contained in one inflorescence; in fact, if an old mature spike is given a sharp knock in autumn, a positive shower of light, flake-like seeds descends, these being carried some distance by very little wind.

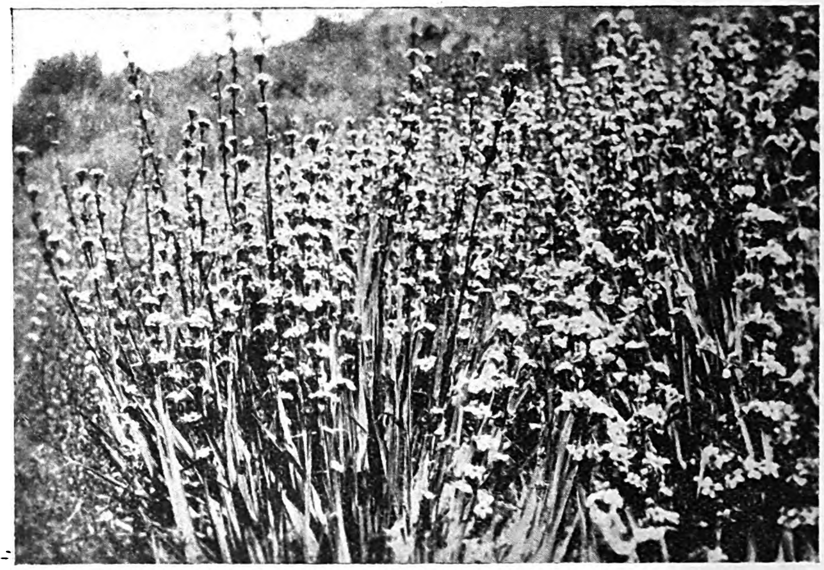

FIG. 110.—SISYRINCHIUM SP. (PROBABLY S. STRIATUM), AT HOME, NEAR VALPARAISO.

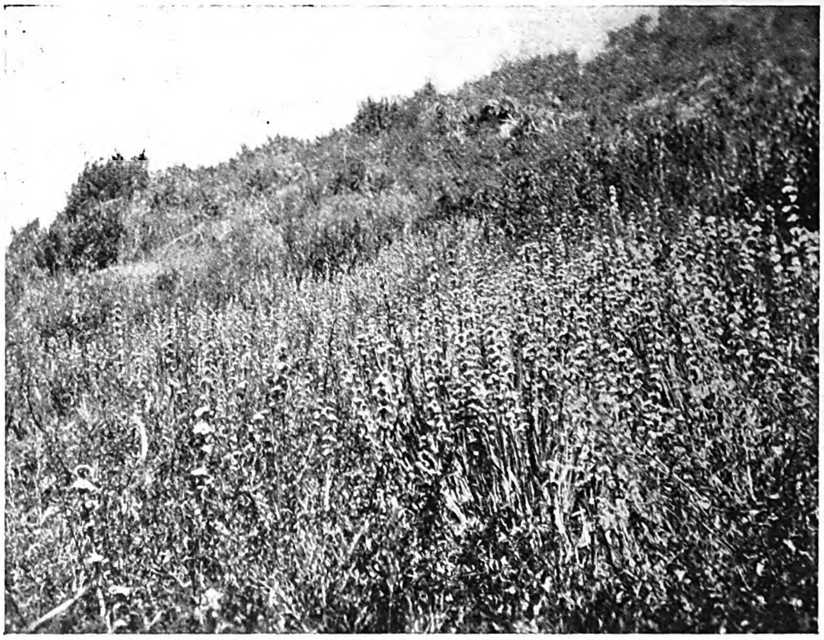

FIG. 111.—SISYRINCHIUM SPECIES, NEAR VALPARAISO.

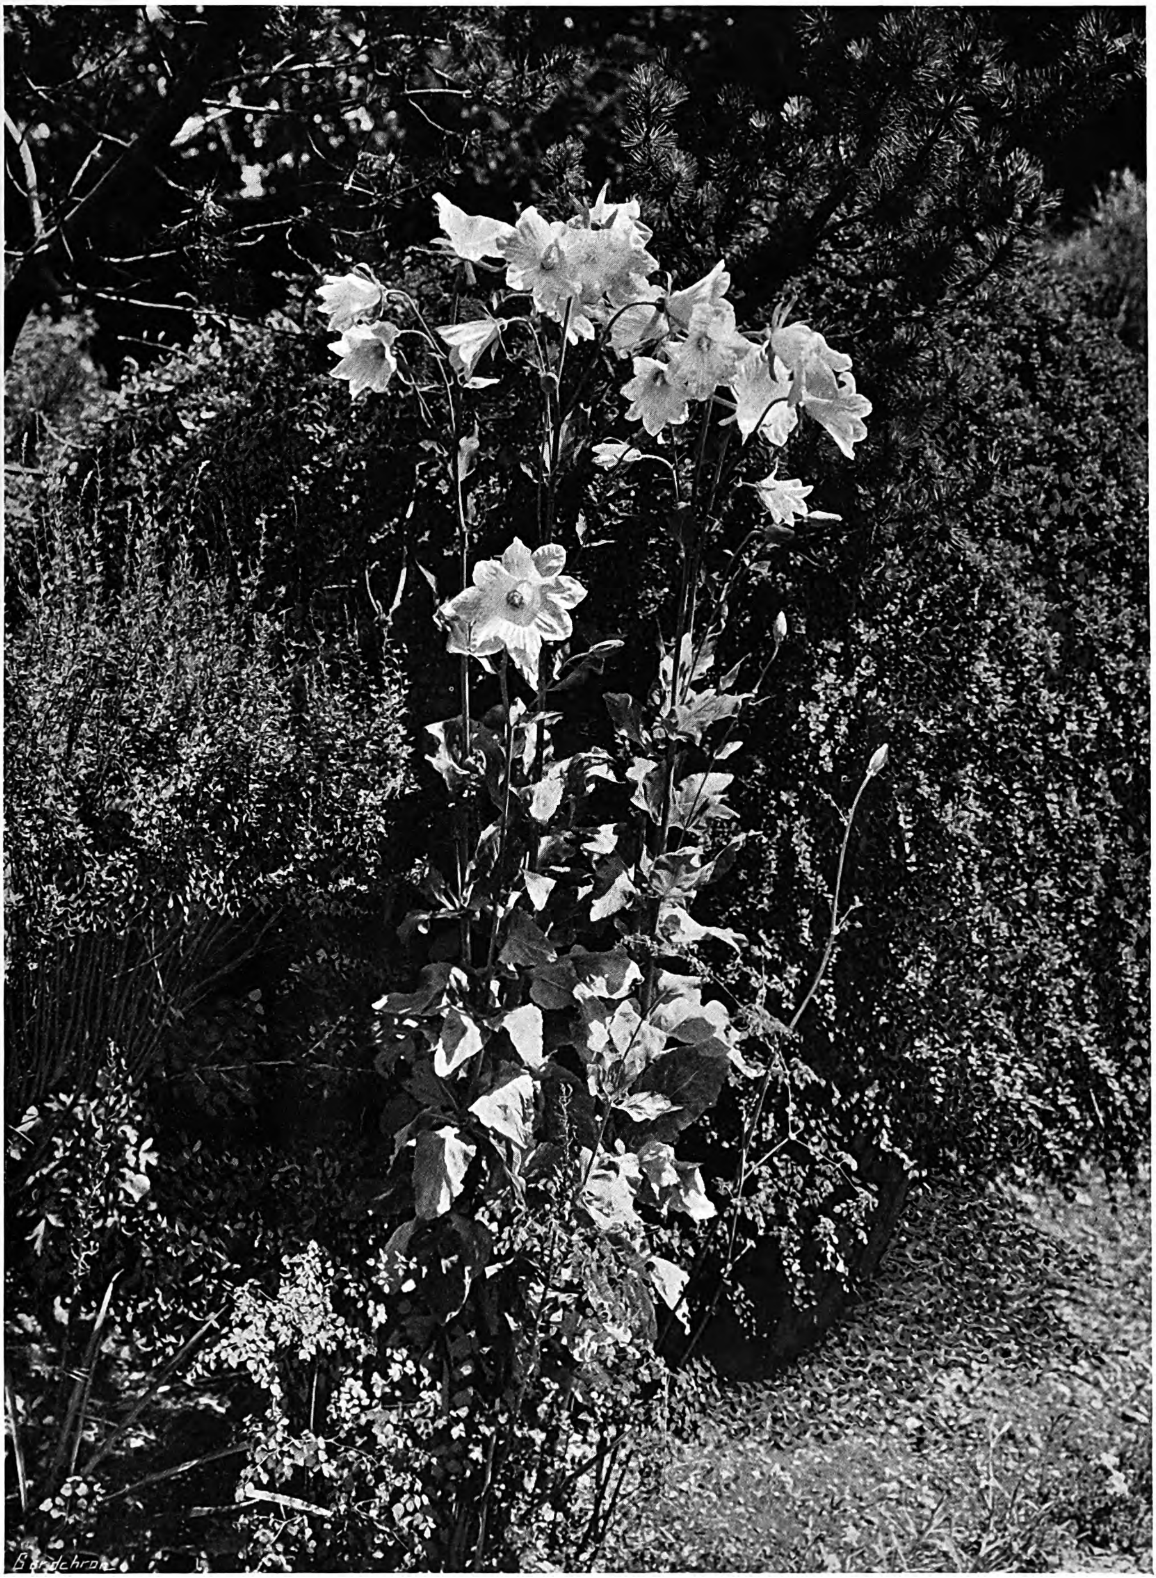
The Puya inflorescence, when arising from the centre of the rosette, may best be compared with an enormous head of Asparagus; the head is slightly swollen and tapering to a sharp point, and the whole is covered with overlapping scales; the stem continues to elongate until the head is several feet high, when the latter commences to swell, finally to branch and flower. It is easily understood that Puyas are no favourites with the farmers and stockmen, especially as they are so effectively protected by spines, equally as formidable on the old, dry dead leaves, which are persistent and continue to protect the stems. This, however, proves to be their weak point, as these dry, dead leaves burn fiercely, and every winter, when there is no risk of extensive fires, large numbers are burned.

Before leaving these sand hills, it is of interest to note that only three species of trees have been successfully planted on these areas. Eucalyptus Globulus is extensively planted, as it is quick-growing and highly valued as fuel; the other two being Cupressus macrocarpa and Pinus maritima. They have to be watered regularly during the first year after planting, by means of donkeys—a laborious business. I have seen established trees of other species of Eucalyptus and of Casuarina stricta, but these are planted only for ornamental purposes. *G. W. Robinson.*

(*To be continued.*)



OSTROWSKIA MAGNIFICA.

MESEMBRYANTHEMUM.

(*Continued from p.* 208).

MITROPHYLLUM, Schwant.

Key to the Species.

1. Plants in flower not more than about 1–1½ inch high.
8. nanum and **Schickianum.**

Plants from a few inches to two feet high. **2**

2. United pairs of leaves forming conical bodies stouter than the branches that they terminate. **3**

United pairs of leaves forming cylindric bodies not stouter than the branches they terminate; dwarf shrublets 6–12 inches high, with distinct internodes. **7**

3. Internodes distinctly developed on both vegetative and flowering parts of the plant and varying from ¼–2½ inches long and 1½–3 lines thick. **4**

Internodes of the vegetative growths suppressed and crowded together or not more than about 1–1½ lines long; those of the flowering parts elongated and ¼–3 inches long. **5**

4. Internodes 1–2½ inches long, and the terminal cone separated from the lateral cones next below it by an internode 1–2½ inches long; free leaves 4–6 lines broad at the base; petals yellow.
5. dissitum.

Internodes ¼–1 inch long, and the terminal cone sub-sessile among the lateral cones or only separated from them by an internode 2–6 lines long; free leaves 4–7 lines broad at the base; flowers unknown.
4. proximum.

5. Vegetative cones 2–3 inches long and an inch or more thick, all basal and practically stemless, being permanently clustered close to the ground; flowering stems arising from vegetative growths and 6–16 inches high, with internodes ¾–3 inches long, dying after fruiting; free leaves 1–1¼ inch broad at the base; petals white.
1. grande.

Vegetative cones 9–16 lines thick at the base, not basal, mostly solitary at the ends of branches and mingled with the flowering growths on various parts of the shrublet; free leaves 6–12 lines broad at the base. **6**

6. Cones 1¼–2½ inches long; internodes of the flowering branches 3–12 lines long and the lower one not resembling a long peduncle; pedicels about 6 lines long; petals white at the base, pale pink at the upper part. **3. mitratum.**

Cones 2–3½ inches long; lower internode of the flowering branches 4–5 inches long, about half as thick as the internode below it and resembling a peduncle; pedicels an inch or more long; petals pure white. **2. Pillansii.**

7. Stem and branches more or less distinctly constricted at the nodes; flowers and fruit unknown. **7. clivorum.**

Stem and branches more or less thickened (never constricted) at the nodes; flowers and fruit unknown. **6. cognatum.**

These plants are not exactly easy to cultivate. They require a good sandy soil and are best watered from below, by standing their pots in saucers of water occasionally, and when the vegetative season commences their roots should not be allowed to completely dry up, at the same time they must not be overwatered, for in the region they inhabit they only receive three or four inches of rain per annum, and subsist for the greater part of their life upon dew or moisture condensed about their roots. Cuttings of some species do not root very readily, but in my experience the best time to take cuttings is in July.

1. M. grande, N. E. Br. (Fig. 112).—Plant with basal vegetative growths all without internodes and seated on the ground and persisting, each growth finally producing a branching stem with elongated internodes, which dies after flowering and fruiting. In the axils of the leaves at the base of the flowering stem are a pair of sessile leaf-cones that carry on the vegetative growth. When at rest, the vegetative cones are 2–3 inches long, an inch or more thick at the base, and somewhat resemble the pseudo-bulbs of an Orchid in appearance; the free leaves are 3–4 inches long and 1–1½ inch broad at the base, thence tapering to an obtuse point, flat on the face, rounded at the back, glabrous, light green in colour. Flowering stem 6–16 inches high, with internodes ¾–4 inches long and 1½–4 lines thick, somewhat compressed and 2-edged, branching in a forked manner, with the branches erect and bearing reduced leaves at the nodes, and a flower in each fork or at the apex. Pedecils 2–6 lines long on native plants, about 1½ line thick, thickening upwards, compressed, papulose. Calyx (only seen on a withered flower) sub-equally 5-lobed, with the ovary part very shallow and broad, and lobes 4–5 lines long, 2½–3½ lines broad, probably larger when alive, oblong, obtuse, 3 of them with a short dorsal point. Corolla 2–2½ inches in diameter, expanding after noon; petals in about 3 series, 9–12 lines long, about ¾–1 line broad, linear, white, shining. Stamens about 2 lines long; filaments white; anthers yellow. Stigmas 5, subulate, about 1½ line long. Ovary with 5 ridges on the flat top. Capsule when closed 5–5½ lines in diameter, very shortly and broadly obconic, with 5 valves and cells, grey; when expanded about 8 lines in diameter; valves spreading horizontally, deltoid; expanding-keels broad and flattish, elevated at the inner edge, diverging from the base, with incurved, awn-like tips and broad membranous margins; cells somewhat acutely roofed with membranous cell-wings. Seeds nearly ½-line long, Pear-shaped, smooth, light brown.

Mesembryanthemum proximum, L. Bol. in *S. Afr. Gard.*, 1927, p. 239, Fig. 3, and *Notes on Mesemb.*, I., p. 70, Fig. 3, not of N. E. Br.

Little Namaqualand: On hills north of Brakfontein, Pillans 4,933.

So far as known to me, this fine species stands alone among those in this genus that have tall

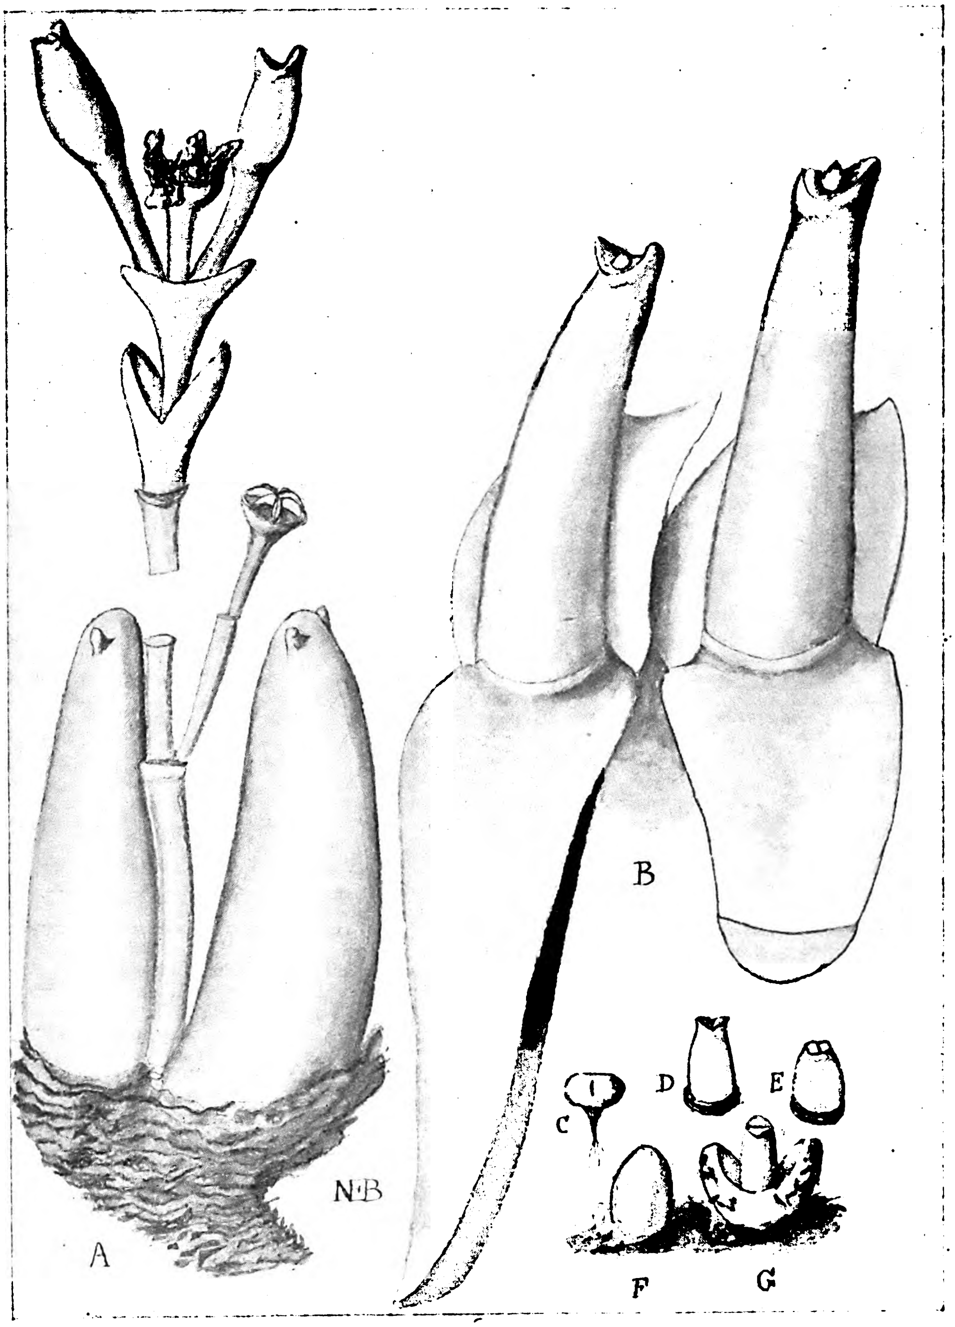


FIG. 112.—MITROPHYLLUM GRANDE.

A.—Two growths at rest, with flower stem abbreviated; B.—The same when making new growth; C—G.—Seedling stages; all natural size.

flowering stem in having its vegetative growths seated on the ground without internodes between the successive growths. It is incomprehensible how it could possibly have been mistaken for M. proximum, as it in no way agrees with either my figure or description of that species, which bears its growths in clusters at the ends of the branches. Fig. 112 represents at A two growths from a clump with a flowering stem derived from a previous sessile cone arising from between them, of which a portion is omitted from the drawing. This flowering stem is probably two or three years old, its lower part bears fruit, and the terminal part has a withered flower and two flowering cones.

Seedlings of this species have the cotyledons as represented at Fig. 112 C, and the succeeding stages as shown in the same figure at D–G; D and E represent seedlings of one year's growth preparing to go to rest; F, a seedling at rest, but about to resume growth in the second year; G, the same at a later date when forming a fresh cone, and with the remains of the skin of the old cone (F) clinging to it. These young cones are of a somewhat translucent light green, and glitter as if covered with minute, watery papulae, but under a lens the cells are seen to project as papulae only on the lobes, elsewhere they do not project into distinct papulae.

2.—M. Pillansii, N. E. Br.—Plant 12–16 inches high. Branches 5–6 lines thick, with the internodes on the vegetating parts 2–3 lines long, crowded, and on the parts about to flower longer and up to 14 lines long, the vegetating and flowering parts intermingled. Cones 2–4 inches long, 1–1½ inch thick at the base. Free leaves 4–4½ inches long, ⅔–1 inch broad and ⅓–¾ inch thick at the base, thence tapering to a sub-acute point, very minutely papulose. Flowers solitary, terminal! the first one on a peduncle 4–5 inches long and 2–2½ lines thick (the equivalent of the lower part of the flowering branches in the other species), with a pair of reduced leaves or bracts at its apex, from the axils of which small secondary flowering cones arise. Pedicel about 1½ inch long. Calyx with the longer lobes 8–9 lines long, and the three shorter lobes with membranous margins. Corolla 1½–2 inches in diameter, opening in the afternoon, scented; petals in 3–4 series, 5–9 lines long, ¾–1 line broad, linear, subacute or obtuse, white. Stamens in a column about 4–4½ lines long and 5–6 lines in diameter, with the outer spreading away from the rest; filaments white, anthers yellow. Stigmas 5, about ½ inch long, exceeding the stamens, subulate, green. Ovary conical and stoutly 5-ridged on the top. Capsule shortly and broadly obconic, about 7 lines in diameter when expanded; expanding-keels closely parallel or nearly contiguous, with narrow marginal wings; cell-wings rudimentary.

M. mitratum, L. Bol. in *Fl. Pl. of S. Afr.*, Vol. VII, t. 274, not of Schwantes, nor Mesembryanthemum mitratum, Marl.

Little Namaqualand: On hills about six miles north-east of Oograbies Poort, Pillans 4,690.

Although figured as being M. mitratum, Schwant., this plant conspicuously differs from that species by its larger vegetative cones, the much more slender and very long and peduncle-like lower part of the flowering branch, longer pedicels and much larger and differently-coloured flowers.

3.—M. mitratum, Schwant. in *Zeitschr. f. Sukkulent*, 1926, p. 182, and 1928, p. 321; not of L. Bol.—A shrublet about 1–2 feet high, with vegetative and flowering growths intermingled on the branches. Vegetating branches 6–7 lines thick, with very short, crowded internodes 1–2 lines long, and the flowering branches about 3 lines thick, with internodes ¼–1 inch long, dark brown. When at rest a vegetative cone is represented as about 2½ inches long and about an inch thick at the base, and a flowering cone about 1¼–1½ inch long and ¾ inch thick. Leaves not represented nor described. Pedicels represented as less than half-an-inch long, and as arising from the axil of the one of the old leaves of a flowering cone, but the flower is described as forcing "its way out through a slit at the side" of the cone. Calyx 5-lobed, three of the lobes with membranous margins. Corolla represented as about ¾ inch in diameter; petals linear, white at the base, pale pink at the upper part.

Mesembryanthemum mitratum, Marl., in *Tr. Roy. Soc. S. Afr.*, Vol. II, p. 35, t. 1, f. 4 (1910), and *Fl. S. Afr.*, Vol. I, p. 205, t. 51, f. C.

Little Namaqualand: Sandy deserts east of Port Nolloth, Alston, in Herb. Marloth 4,690.

This species is unknown to me and evidently it is not the same as the plant figured by Mrs. Bolus under the name of M. mitratum, its cone being smaller, flowering in a different manner, and its flowers smaller and different in colour. *N. E. Brown.*

(*To be continued*).

GARDENING TWU CENTURIES AGO.

Among a number of quaint old books, which have come down to us, few are more suggestive of enormous strides of human knowledge than *The Compleat English Gardener; or, A Sure Guide to Young Planters and Gardeners.* It professes to teach "The ordering of a garden of pleasure with variety of Knots and Wilderness Work after the newest fashion."

At the end are no fewer than twenty-three diagrams for the laying-out of gardens—called, most inappropriately "Wilderness Work," but in their prim stiffness more suggestive of patterns for chip carving than designs for dealing with living plants. The only other illustration is of a man in modern-looking "plus fours" and a long-skirted coat in the act of "inoculating" very elderly-looking fruit trees with new grafts. No date is on the title-page of my copy, but against one of the many owners names scrawled on the cover is "Samwel Wheatcroft, his booke, 1721."

It was evidently a popular work, for mine is the Eleventh Edition. As to the authorship, we are told it was "Begun by Leonard Meager above thirty years a practitioner in the art of gardning, and now enlarged by a Lover of this Princely Diversion and Profitable Recreation. Printed for Mr. Wotton at the Three Daggers in Fleet Street, price 4s." There is a short preface, beginning "Reader," recommending the "compleatness" of the book, disparaging all others on the same subject, and concluding, "Farewel. S. G."

The advertisements of contemporary books are amusing: "The History of Bees, showing their Admirable Nature, their Government, Loyalty and Industry, Enemies, Wars and Magnanimity, together with the right ordering of them"—doubtless a very different "ordering" from our modern frame and section hives and honey-extractors. "The Way to Save Wealth; or How to Live on 2d. a Day." "The Way to get Wealth by making 23 sorts of English Wine, equal to French." "Markham's Masterpiece, showing how to cure horses and all kinds of black and white cattle."

The author is great on grafting and the budding of Roses. He gives a catalogue of fruit trees to be obtained at "Mr. Colchester's, at the Ducking Pond, Clerkenwell Green" and other places. There are in his list five-and-twenty kinds of Cherries, six "Apricocks," six Figs, including "Blew Spanish," eleven Grapes, and long lists of Apples and Pears with quaint and obsolete names. What modern gardener ever heard of a "Davey-gentile Apple," or a "Pig's tale pear"?

When we come to the list of "Divers pretty flowers fit to furnish a garden," the old names are very amusing. What can "Melancholy Gentleman" have been? "Great Blew Bindweed or Connuvolus Major" is more comprehensible. "Larks heel or Spurs—divers varieties." "Spanish tufts." "Ladies Smocks." "Double Sopewort—a busie runner in the garden"—this characteristic has not changed with the centuries, as we know to our cost! "Munkhood," "Mollies," "Flowerdeluces," "Sultan's Flower or Turkey Corn Flower" and "Jerusalem Cowslips" probably were all favourites in the flower-beds of Queen Anne's time.

Chapter VII is headed "Rare Curiosities in Gardening, being secrets known to very few." "To make a Sallad grow from seed in three or four hours, fit to cut and be brought to table" sounds startling! Ashes of moss and manure were to be worked together, dried several times in the sun, spread upon an iron plate over a slow fire and sprinkled with warm rain water. In this you were to plant seeds of "Purslain or Lettice" that had been soaked in warm water "mixed with dregs of Oyl," and this very rapid crop might be expected!

To make Tulips and other flowers of the colour you are pleased to have them, the seeds are to be soaked in dye. "For black, ink; green, verdigrease; yellow, tumeric. Sow them in proper ground and you will find blowing in due time a wonderful change!" "How to produce double Gillieflowers of any seed whatever." "Take a bean and put into it the seed of a single Gillieflower, stopping the hole with a little soft wax, and a Gillieflower will spring from it double and large!" "To make Gillieflowers of extraordinary bigness mix bean flower with the soil." In spite of spelling, this must refer to meal, not bean blossom. "To make a Peach tree bear with writing on the fruit":—"Take the stone of a good bearing Peach, bury it in suitable soil till it be half open, so take out the kernel gently without breaking it, and write on it with vermilion made liquid in the beaten white of an egg, and with a pen write what you please on the kernel. Then put the kernel the right way into the shell, close it with a little soft wax, and when it produces a tree bearing fruit the words in a lesser or greater measure will appear on the Peaches!"

Could anyone have really believed such stuff as this? Yet it is all told with such engaging confidence and simplicity! Is it possible that in a couple of centuries our modern books will seem as ridiculous in the eyes of posterity as this does to us?

Our gardener had a greenhouse to preserve his "Orange and Limon" trees in winter. This was to have sashes on the south side and—"I approve it rather to be thatched with a thick coat of wheat straw or fine reeds than to be tiled or slated, for though in a nobleman's or gentleman's garden it is not so sightly, yet it abundantly more keeps out the cold air." You are to take care that no noisome insects lurk in this house to infest the plants with their bites or venomous spume, and if you perceive such marks smoak it with franincence or storax." This greenhouse was to be heated with "Old coal or charcoal" in a stone-built stove.

There is a short chapter on "Prognostics, or Observations on the Moon," directing when to sow and plant. "Prune your vines when the moon is full, and it is held that neither bird nor insect will infect your Grapes." "When the moon is in Cancer, set and sow all sorts of pulse." "If you are desirous to have low or dwarf plants, then it is held proper to cut, set and plant in the Wain of the Moon."

Passing over the chapter "To order Vineyards" (it must have needed a sanguine temperament to attempt Vine culture in our climate), we come to recipes for herb teas and other medical nostrums. "The roots of White Brony bruised and apply'd of itself to any place where the bones are broken helpeth to draw them forth, as also splinters, arrow heads, and thorns in the flesh." "Hounds tongue is good against the biting of mad dogs, and laid on the bottom of your feet Hounds will not bark at you!" "Mistletoe hung round the neck Witches can have no power over you." "Mugwort worn under the soles of your feet you may travel forty mile and not tire" (very convenient this in pre-cycle and motor days!). "Adder's tongue cureth the biting of an adder. Viper's bugloss is a remedy against the stings of vipers and other venomous beasts. Arrowhead is good for a wound made with an arrow!" How simple it all sounds if one could only believe it!

Poor old book, in its well-worn brown leather cover—its day is past, its knowledge has vanished away, but it may afford a brief amusement to some readers who still find pleasure in the "Princely Diversion and Profitable Recreation" of gardening. *Maude Robinson.*

RELIEF OF RATING UF AGRICULTURAL HEREDITAMENTS.

PERHAPS the most important legislative measure of recent years has been the new system of rating, and the derating of agricultural land and buildings, completed by the late Government during the closing session of the late Parliament. Five Acts in all were necessary, the Rating and Valuation Acts, 1925 and 1928, the Rating and Valuation (Apportionment) Act, 1928, and the Local Government Act, 1929. In addition, the Agricultural Rates Act, 1929, was passed, making the derating enactments retrospective to April 1, instead of from October 1, as originally provided for.

This article will endeavour to explain as simply and plainly as possible those particulars pertinent to anyone who comes, by his premises, within the scope of the different Acts. The Agricultural Act, 1929, will be dealt with at the end of the article.

The Apportionment Act, 1928, which might be called the classification act, called upon local authorities to distinguish in special lists hereditaments under the following headings:—(*a*) Agricultural, (*b*) Industrial, (*c*) Freight-Transport; but, of course, the writer will confine himself to those under heading (*a*), Agricultural.

This Act contains a definition of "Agricultural hereditaments," which enlarges that hitherto used. It includes woodlands, etc., hitherto rated, and also brings in poultry farms. Also "agricultural buildings" are more clearly defined.

The Act reads—

"The expression 'Agricultural Hereditament' means any hereditament being agricultural land or buildings." Moreover—

Agricultural Land means any land used as arable meadow or pasture ground only, land used for a plantation or wood, or for the growth of saleable underwood, land exceeding one-quarter-of-an-acre used for the purpose of poultry farming, cottage gardens exceeding one-quarter-of-an-acre, market gardens, nursery grounds, orchards or allotments, including allotment gardens within the meaning of the Allotments Act, 1922, but does not include land occupied together with a house as a park, gardens (other than aforesaid), pleasure grounds, or land kept or preserved mainly or exclusively for purposes of sport or recreation, or land used as a racecourse; and for the purposes of this definition the expression "cottage garden" means a garden attached to a house occupied as a dwelling by a person of the labouring classes.

Agricultural Buildings means buildings (other than dwelling-houses) occupied together with agricultural land or being or forming part of a market garden, and in either case used solely in connection with agricultural operations thereon.

Allotment Gardens.—The definition of "allotment garden" in the Act of 1922 is an allotment not exceeding forty poles in extent which is wholly or mainly cultivated by the occupier for the production of vegetable or fruit crops for consumption by himself or his family.

Special Valuation Lists have been prepared under this Act, which, in addition to particulars already given on the main Valuation Lists under the 1925 Act, apportioned as to "Net annual value" parts of the hereditament (if necessary) as woodlands, other agricultural land and buildings. Also, rateable value was mentioned, but in regard to the latter the entry on list, if accepted as under the heading of "agricultural hereditament," will be "nil," thus no rates are payable on these parts.

These special lists will have been incorporated with the main valuation lists, and the particulars will thus be scheduled as required, with Farm House, Farm Buildings and Agricultural Land entered as to amounts apportioned to each. Gross value (if any) of the entire holding will also be entered in particulars in possession of Rating authorities.

If a person has nothing but what comes under any of the definitions as above, he will be absolutely exempt from the payment of ordinary rates.

If his holding comprises also dwelling house, he will be required to pay rates on this part of his property. It should be mentioned that in the assessing of this part of the property it is laid down in the Local Government Act, Section 72, that if the person who uses the dwelling-house is primarily engaged in carrying on or directing agricultural operations on the agricultural land connected with the dwelling-house, the estimated valuation must be made by reference to the rent at which the house might reasonably be expected to let from year to year if it could not be occupied and used otherwise than as aforesaid. Thus his assessment should be less than if the house was assessed as a dwelling-house for general use. It might here be mentioned that although the rating authority has wide discretionary power as to estimating what they think a hereditament is worth for rating purposes, the Central Valuation Committee (an advisory Committee to Local authorities) gives a formula for arriving at the rateable value to be apportioned to the dwelling house and farm buildings. Thus the gross value of the farm should be first ascertained or estimated. Then one-eighth should be taken as the value of the dwelling-house and farm buildings. Then the dwelling-house is to be taken as not less than sixty per cent. of this total. There are certain deductions allowed from gross value to arrive at "net annual value" which would be the amount upon which rates would be paid. An example may be quoted.

Gross Value of Farm ...	£240 per annum.
One-eighth for Dwelling-house and farm buildings	£30
For Dwelling-house 60% of £30 = ...	£18
Less deduction allowed under the Act	£7
	£11 per annum.

FIG. 113.—SOUTHPORT SHOW: MESSRS. BEES, LTD.'S FORMAL GARDEN.
(see p. 194).

Thus rates would be paid on £11 only.

Under this Act there is an additional authority, the Revenue Officer, an officer or person appointed by the Commissioners of Inland Revenue. This authority, of course, enters into the scheme by virtue of the fact that the Exchequer will be required to make grants to replace the amounts lost to the local authorities by the exemption from rates of most of the holding. If he disagrees with the rating authority as to values, or whether such property shall be accepted as agricultural, a consultation between these parties must take place. On the Special Lists, in addition to those hereditaments upon which the two bodies mentioned agree, there shall also be entered the conclusions of the two parties separately, when not in agreement. In the latter case, the Assessment Committee shall consider the particulars and after giving the two authorities fourteen days' notice of hearing, and the opportunity of calling and examining witnesses, shall enter on the list such particulars as they may think proper. Such decision shall be deemed to be a decision or an objection. If, however, the rating authority and the Revenue Officer are in agreement, the Assessment Committee has no power to alter any particulars except, of course, on an objection being entered and heard.

Objections.—It should be noted that, if anyone is aggrieved at the incorrectness or unfairness of any matter in the list, or the exclusion altogether from the list, he can enter an objection at any time, under Section 37, on forms provided. The objection is to be made to the Assessment Committee, which will give a decision. If then not satisfied, appeal is allowed to Quarter Sessions. It is important to remember that no action by any occupier of an agricultural hereditament was required to be taken in the compilation of the First Valuation List to exempt premises mentioned, but after the appointed date if any hereditament has changed its status by coming under the "agricultural hereditament" heading, claim for inclusion as such and exemption from rates must be made by the occupier, by way of an objection. Also any alteration in values desired must be secured by an objection. If in the opinion of the Rating Authority a hereditament has ceased to be an agricultural hereditament after the appointed day, such authority cannot alter same on lists, except on application by a "proposal" under Section 37 to the Assessment Committee, which will decide. In such an event, the occupier or owner, if either disagrees, can enter an appearance against the authority. Otherwise the conclusions in list must remain until the next general valuation, which will be held, for most districts, at practically speaking, every five years.

Assessment Committee.—At present and until April 1, 1930, an Assessment Committee for a county borough, is appointed by the Council, but not less than one-quarter must be of the Board of Guardians, and not less than one-fifth shall be persons outside both Council and Board of Guardians. In the case of any other Assessment Committee, it shall consist of persons appointed by the Rating Authority, the Board of Guardians, and the County Council. The proportion of each body is to be determined by the scheme constituting the area.

Rating Authority.—For a county borough this is the Council. For a county district, the Rural or District Council.

Water Rates.—Section 77 of the Local Government Act makes provision that where the water rate or charges is based on rateable value, for this purpose as there is now no rateable value for "agricultural hereditaments," the rate shall be based on the "net annual value." Where the net annual value does not appear on any valuation list, the value of the water rate is to be determined in case of dispute by two Justices of the Peace.

Agricultural Workers.. — The basis of assessment of a farm cottage used as a dwelling-house by a person employed in agricultural operations, where residence depends on employment on the particular agricultural land in connection with which the cottage is occupied, is the same as with a dwelling-house of the occupier of the farm. Thus the estimate must be made by reference to the rent at which the house might reasonably be expected to let from year to year, if it could not be occupied and used otherwise. Cottages not in this category will be assessed as ordinary cottages, notwithstanding that they may be occupied by agricultural workers.

Agricultural Rates Act, 1929.—The object of this Act was to bring forward the exemption from rates of Agricultural Hereditaments from October 1 to April 1. It is provided that if rates have been paid for this period April 1 to October 1, repayment should be made by the authorities to the person who has so paid.

Where rates have not been paid, a notice was to be issued by the authority acquainting the ratepayer of such exemption from rates, with the proviso that if such hereditament was afterwards found not to qualify as "agricultural," then the rates would become payable.

The test as to what constitutes an "agricultural hereditament" was to be the inclusion in the Special Lists prepared to operate from October 1. Where the Revenue Officer and Rating Authority are in disagreement, as explained earlier, the withholding of such payment of rates would still operate until a decision was given.

If premises are down on Special Lists, and the Rating Authority or Revenue Officer question the presumption that such premises are Agricultural during the half-year April 1 to October 1, they can apply to the Assessment Committee for a decision. If the Assessment Committees agree with the objection, a certificate will be issued giving the exact dates when such premises were "Agricultural," or stating that they were not such for any part of this half year. If it was "Agricultural" for the whole of the period, then no certificate will be issued, the presumption being it was proved that it was such, and rates can be withheld. If an hereditament is not shown on the Special Lists, application can be made by the occupier for such inclusion, and for the exemption from rates to operate from April 1 to October 1, to the Assessment Committee, any time before November 1 next.

Agricultural Selected Traffics.—Under the Freight-Transport Section, the rebate of seventy-five per cent. allowable, must be passed on to the user, by the reduction of carriage charges on certain selected traffics. By the railway rates anticipation scheme, certain reduction in freights took place from December 1, last, but when this portion comes completely into force as from October 1 next, freights should be lower still for the following :—

Manure, street, stable or farmyard, in bulk; manures, other than street, stable or farmyard, in bulk; used in Great Britain.

Lime, limestone, chalk, basic slag and salt for use as manure; any other substance for use direct as manure, or any manure substance to be mixed and used as manure, when packed and so consigned; used in Great Britain.

Grain, ground or flaked; oil cake, whole, broken or ground; meals or husks, in cases, casks or sacks; foods consisting of meals, with spice, molasses or condiment; milling offals, included in the grain list in the Classification of Merchandise; treacle delivered direct to farmers; ensilage; hay; hay or straw, chopped; provender, consisting of chopped hay or straw, mixed with articles included in the grain list in the Classification of Merchandise for conveyance by railway; Beetroot pulp (residue from sugar-making); Carrots, Mangel Wurzel, or Turnips, in bulk; grains, brewers' or distillers' (or draff); used in Great Britain for livestock or poultry feeding.

Potatos, except new Potatos as defined in the Classification of Merchandise for conveyance by railway.

Milk (including separated milk, but not condensed or dried milk).

Live Stock. *F. T.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

THERE is no more lovely colour among September flowers than the soft blue, faintly tinged with violet, displayed by a form of Cynara which has been here for many years. It seems to differ from the ordinary esculent Globe Artichoke only in its hard, thorny involucre; but it may be a different species, entered in the Kew *Hand List* as Cynara Cardunculus, L., with which I am not acquainted, nor have I any authority at hand to enlighten me. I would be grateful for information about it.

Mention of the Globe Artichoke brings to mind a slip which the late Canon Ellacombe made in his *Plant Lore and Garden Craft of Shakespeare*. After quoting Falstaff's ejaculation when he met Mrs. Ford and Mrs. Page in Windsor Park—

> "Let the sky rain Potatoes: let it thunder to the tune of Green Sleeves, hail kissing comfits and snow Eringoes!"

He proceeds—

> "I am inclined to think that the vegetable he [Falstaff] wished for was the Globe Artichoke, which is a near ally of the Eryngium, was a favourite diet in Shakespeare's time, and was reputed to have certain special virtues which are not attributed to the Sea Holly, but which would more accord with Falstaff's character."

It is strange that a botanist and gardener of such experience as Canon Ellacombe should have erred in describing the Globe Artichoke and the Sea Holly as nearly related, seeing that the former belongs to the Composite Order and the latter to the Umbellifers. The error would not be worth recalling, were it not that Falstaff's prayer for "eringoes," meaning the Sea Holly, whereof the candied roots came, through another blunder, to be esteemed as an aphrodisiac. Pliny the Elder raked uncritically into his discourse on plants all current beliefs in their virtues and vices. In treating of Eryngium, the Sea Holly, he declares it to be a remedy for snake bites and other poisons, but has not a word to say about its amative properties, which he assuredly would have done had such been popularly attributed to it. On the other hand, he describes Eruca (a native of the Mediterranean region belonging to the Cruciferae or Cress family, and known in modern botany as Eruca sativa) as a strong aphrodisiac, and this plant is extolled as possessing that property by the classical writers Ovid, Martial and Columella. It was through confusion between the names Eruca and Eryngo that the inoffensive Sea Holly became credited with qualities which it never possessed.

Trees and shrubs vary very much in being able to flower and bear seeds with equal profusion in consecutive years. Double-flowered Hawthorns show no variation in that respect, because they bear no seeds, but the single-flowered form claims a season's respite after a heavy crop of haws. It is one of the merits of Eucryphia pinnatifolia and E. cordifolia that they never vary in that respect. Year after year they are loaded with blossom, which is followed by plenty of seeds, yet the plants never betray any symptom of exhaustion. Among seedlings of E. pinnatifolia there are always some which bear double flowers, which are no improvement on the type, for the singular grace of the blossom is marred, although the display is somewhat prolonged beyond that of the single-flowered plant. *Herbert Maxwell, Monreith.*

THE GENUS PRIMULA.

(*Continued from p.* 205.)

REIDII (Duthie). Reid's P.
(Soldanelloidae).

THIS exquisite Himalayan species is a perennial, but gives the best results when treated as a biennial in cultivation. It produces a tuft of membranous, broadly lance-shaped, blunt leaves from two to three inches long, tapering to a winged stalk shorter than the blade; margins coarsely toothed or lobulate; upper surface convex, very deeply divided by the larger nerves as though blistered, covered with lax, white hairs; underside very hairy. Flower stem erect, three to four inches tall, coated with white meal and bearing an umbel of three to ten ivory-white, nodding, nearly stalkless blossoms. Corolla five-eighths- to one inch across, concave, with broadly oblong, notched lobes with a tooth in the notch; tube cylindrical, dilated upwards, about as long as the calyx. Introduced in 1884. *Gard. Chron.*, 1911, Vol. XLIX, p. 195, Fig. 87. *Bot. Mag.*, t. 6,961.

Grows in glacial moraines and damp, rocky soil in the Garwhal and Kumaon Himalayas, at 12,000 to 13,000 feet above sea-level.

Culture: Grow it in limestone chips, peat, and a little fibrous loam, well-drained, with abundant underground moisture when in growth; protect from damp in winter. It gives the best results under frame cultivation.

REINII (Franch.). Reini's P.
(Reinii).

A desirable deciduous perennial species with a tuft of rounded or kidney-shaped leaves one to three inches across, deeply heart-shaped at the base, borne on stout, rounded, hairy stalks one inch to four inches long; margins deeply lobed and toothed; both surfaces clothed with long, pale-coloured hairs. Flower stems four to six inches tall, stout, hairy, bearing an umbel of two to six lilac or pale violet blossoms, with a yellow eye, on fairly long stalks. Corolla about one-and-a-half inch across, divided into five broadly wedge-shaped, deeply and broadly notched or bifid lobes with rounded angles; tube cylindrical, about five-eighths-of-an-inch long, more than twice as long as the calyx. In cultivation in 1915. *Gard. Chron.*, 1915, Vol. LVII, p. 214, Fig. 66.

Grows in damp, shady places on Mount Haksan, in the province of Kanga, Nippon, Japan.

Culture: Good, fibrous loam, leaf-soil and limestone chippings, in a cool, sheltered part of the rock garden, with protection from damp and severe frost, are the conditions indicated.

reptans (Hook. f.). Creeping P. (Minutissimae).

A beautiful, prostrate perennial species with a creeping stem clothed with minute tufts of non-mealy, deep green foliage. The leaves are from one-sixth- to a quarter-of-an-inch in length, with rounded, convex blades cleft one-third of the way down into several lobes or coarse teeth, giving the blade a palmate appearance; it is suddenly contracted into a stalk about a quarter-of-an-inch long; both surfaces clothed with minute down. Flower stem obsolete or very short, with very short stalks bearing one or two erect, pale purple blossoms half- to five-eighths-of-an-inch across, with broadly heart-shaped, deeply notched or bifid lobes with rounded angles; tube about three-eighths-of-an-inch long, cylindrical below, with a narrowly funnel-shaped mouth. Flowers in July.

Grows in stony, alpine pastures among very short herbage, near the Bargi-Kang Pass and Bargila, in the Kumaon and Kashmir Himalayas, at 14,500 feet above sea-level.

Culture: As for P. minutissima, not difficult to grow (see *Gard. Chron.*, July, 1928, p. 49). *A. W. Darnell.*

(*To be continued.*)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)
(*Continued from p.* 210.)

ENGLAND, S.

Hampshire—The sharp winter frosts damaged the Strawberry plants very severely, all foliage being cut entirely off, and many plants killed outright. Consequently those plants that did survive were weakened. This was followed by dry spells, particularly after the fruits had set, when rains would have assisted so much. The rainfall up to July 1 was 9·75 inches less than to the corresponding date of last year. Raspberries, Gooseberries and Red and Black Currants have carried very fine and heavy crops. Plums on walls are good, as are Pears in a like position. Apples when just in full bloom experienced two very cold nights with rain and much wind; still, Lane's Prince Albert, Bramley's Seedling, Lord Grosvenor, Wealthy, Mère de Ménage, Early Victoria, Blenheim Pippin, Miller's Seedling, Lady Sudeley, Beauty of Bath, Warner's King, Golden Spire, and others, are fruiting well. Cox's Orange Pippin in this district will be a very short crop indeed; fortunately the trees are making most luxuriant growth. *George Ellwood, Swanmore Park Gardens, Swanmore.*

—— The fruit crops here, generally, are good, Apples especially so, for nearly all varieties are carrying good crops; the trees are clean and the best sorts are Lord Grosvenor, Worcester Pearmain, Ribston Pippin, Charles Ross, King of the Pippins, Newton Wonder, Gascoyne's Scarlet, Bramley's Seedling and Lane's Prince Albert. Most varieties of Pears are carrying fair crops. Plums are bad—the worst for several years, although the trees flowered well. Cherries were a fair crop, and the trees are clean, while Peaches and Nectarines are light but very good. Strawberries have been very good, for the fruits, although not large, were of grand quality. Small fruits were very good, especially Gooseberries and Raspberries. Black Currants were light but of good quality. The soil here is a medium loam on limestone. *George Summersell, Buriton House Gardens, Petersfield.*

—— The fruit crops in these gardens and throughout the surrounding district are, on the whole, very good. Apples are an average crop, and the fruits and trees are clean and healthy. Pears are abundant, most sorts yielding well. Plum trees are looking well, and most varieties have a good sprinkling of fruits. Peaches and Nectarines on walls are the best crop for several years, and the trees are entirely free of leaf-blister. Strawberries were practically a failure again, late frosts playing havoc with them when in bloom. All small fruits fruited well, Black Currants especially, also Raspberries, of which the variety Lloyd George has a very heavy crop. *A. J. Legge, Dogmersfield Park Gardens, Winchfield, Basingstoke.*

—— On the whole, the Apple crop is below the average, although early varieties—Irish Peach, Lord Grosvenor, Lady Sudeley—are carrying heavy crops; mid-season and late varieties suffered severely from the late frosts. In sheltered positions in the orchard, the most noticeable varieties for quantity are Annie Elizabeth and Dumelow's Seedling. Peaches and Pears on walls are carrying their usual good crops, as these were protected during the flowering period. The soil here is deep loam over flint and chalk, with patches of light clay in various parts of the garden. *J. A. Rogers, Hackwood Park Gardens, Basingstoke.*

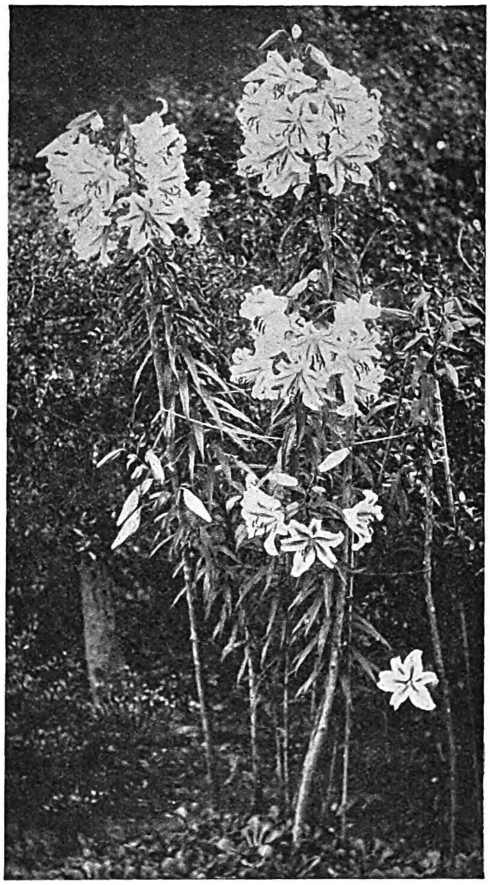

FIG. 114.—LILIUM AURATUM.

——The fruit crops in this district are not so good as usual, but in these gardens Apples are an average crop. The best croppers are Keswick Codlin, Lane's Prince Albert, Cox's Orange Pippin and James Grieve. Pears are an average crop, so also are Plums; of Cherries, Morellos were the best. Raspberries and Black and Red Currants fruited heavily, but Strawberries were very poor, both in quantity and quality. The dry weather was the chief cause of the failure of this crop. The soil here is heavy clay. *William George Osborne, Sutton Manor Gardens, Sutton Scotney.*

Kent.—It is chiefly owing to the lack of rain and the soil being of a sandy nature that the Strawberry crop was poor this year. Peaches and Nectarines on walls have fruited exceptionally well, and this year needed thinning. I think the poor crop of Plums is due to the fact that they fruited so heavily last year. All small fruits cropped exceedingly well. *G. R. Pierce, Huntleys Gardens, Tunbridge Wells.*

—— Among Apples, Bramley's Seedling, Lane's Prince Albert, Grenadier, Worcester Pearmain, Early Victoria and James Grieve are all carrying full crops; Cox's Orange Pippin, average; and Newton Wonder, Bismarck, Rival, and Annie Elizabeth, under average. Emile d'Heyst, Conference and Fertility Pears have full crops, but other varieties are poor. Plums are very variable, Czar, Giant Prune, Yellow Egg and Belle de Louvain all have fairly heavy crops, but Victoria, River's and Purple Egg, are poor. Drought was undoubtedly responsible for the low yield of Raspberries, while the severe winter, followed by drought, greatly affected the Strawberry crop. The soil at this station is light loam overlying Kent ragstone. *R. G. Hatton, Research Station, East Malling.*

(*To be continued.*)

HOME CORRESPONDENCE.

Lilium auratum.—I enclose a photograph of my Lilium auratum (Fig. 114), which may interest your readers. In spite of the drought, and the hard winter—we registered 20° of frost—it is flowering splendidly. The two bulbs were planted nearly five years ago, behind some shrubs facing north, so that the roots are always in the shade. There are seventy blooms on the six heads, the tallest of which reaches seven feet, and carries twenty-one flowers. *M. S. Roberton, Harraby Green, Broadstone, Dorset.*

American Method of Rooting Cuttings.—I was interested to read Mr. Everett's account of the American way of rooting cuttings (August 24, p. 154). The same method has, I believe, been in use in many English nurseries for a number of years. Shortly after the war, upon leaving college, I was working at a hardy plant nursery in Yorkshire, where this method was in constant use for all kinds of cuttings. In particular, the use of a straight-edge or knife blade was employed not only for the placing of cuttings, but also, upon occasion, for the pricking out of seedlings. I have myself constantly used a straight-edge in the disposal of seedlings in the open in my garden. I understood at the time that this method was an old north country labour-saving device, the nursery in question being an old-established one, having been in the hands of members of the same family for over one hundred years. *Vera F. P. Day, N.D.H.*

——In his interesting notes under this heading in your issue of August 24, p. 154, Mr. Everett gives some very convincing facts, and one instinctively wonders why such a method is not adopted in English gardens. So far as Pelargoniums are concerned, it does seem possible that the insertion of cuttings in heat at this time of the year means that the winter-housing of the consequently quickly-rooted cuttings is a far more expensive proposition than our present method of keeping them under cooler conditions. Particularly would this be noticeable where large quantities have to be raised. At the Borough Cemetery here (Cambridge) many Pelargoniums are used for the summer planting of graves, and our usual method is to select cuttings for this purpose from the potted-up stools of the previous summer. These stools, on being returned from the beds about the town in October, are potted and placed in a frost-proof greenhouse and little water given. In February, the house is made warmer and by the end of the month young growths begin to appear on the old stools, which growths, so soon as they have made three good joints or nodes, are taken off, placed singly in three-inch pots containing a very sandy compost, and taken to a house in which the temperature does not fall below 60°F. Here the pots are placed on planks over hot-water pipes along the back of the benches, and their further treatment consists of frequent sprayings and the removal of the pots to a sunny shelf near the glass when the cuttings are rooted. We find this method particularly suited to cuttings of the variegated-leaved Pelargoniums, such as Mr. H. Cox, Mrs. Pollock, Happy Thought, Mrs. Quilter, Caroline Schmidt, etc. *W. Howell, Cambridge.*

An Excellent Indoor Peach.—Quite our best mid-season Peach, both here in Buckinghamshire and down in Gloucestershire, is Peregrine; the fruits are finely coloured, of first-class flavour and good size, and it is a very reliable cropper. The tree grows well on most soils. The fruits are, perhaps, a trifle soft for packing purposes, and they need careful handling when picking, but generally they pick well, when ripe. The tree carried good, healthy foliage, and is quite an easy variety to grow, not being so indifferent to general treatment as some other varieties. Here it receives cool house treatment. *G. H. Emmett, Taplow Court Gardens, Taplow, Bucks.*

FOREIGN CORRESPONDENCE.

FASCIATION IN LILIUM AURATUM.

The article re Lilium auratum in your issue for August 17 (p. 126), in which the writer reports a plant with a fasciated stem producing forty-eight perfect flowers, causes me to send you herewith an article written by me in 1891, and published, with a picture, in the *Deutsche Gärten Zeitung*, in which the ordinary Lily stem shows twenty-two buds and flowers, and the fasciated stem 113 buds and flowers.

I had, last year, here in my garden in Heidelberg again such a plant, which likewise showed a fasciated stem with a great many blossoms, but nothing like the one I had so far back as 1891. *Alfred Unger, Heidelberg.*

[The illustration referred to by Mr. Unger shows an extraordinary example of fasciation.—Eds.]

MAZUS STOLONIFER.

Among the Gratiola tribe of Scrophulariaceae, Mimulus and Torenia are widely known, but the lovely genus Mazus is not so familiar in gardens. Mazus is distributed in Australasia and Asia, where Japan has two species, viz., M. japonicus and M. stolonifer. The former is annual, while the latter is perennial, and is superior to the former in beauty.

M. stolonifer is of spreading habit, with, as the name suggests, slender, creeping stems, which root at the nodes and form a close ground-cover. The leaves are small and elliptic in shape, while the radical leaves are somewhat larger, oblanceolate, and of a pleasing shade of green. The flowers, which are produced continually from spring to summer, are one-and-a-half centimetre in width, and produced in subsecund racemes. The colour is purple, with a white central blotch on the yellowish-brown lower lip.

This moisture-loving plant grows on the margins of streams where the soil is not always saturated, but the flowers in somewhat shady places are darker and more lovely than those in sunny positions. There is a white-flowered variety.

Mazus is easily propagated by means of seeds or by cuttings, which root readily. In England it might, I think, be useful as an edging in the cool house. I am sure it would make a most lovely and floriferous subject for this purpose.

GENTIANA ZOLLINGERII.

This tiny biennial Gentian is very lovely. In the Pine and Oak (Quercus serrata) woods, where the sun penetrates freely, it pushes out, here and there above the fallen leaves, stems which cover the ground. The soil is clayey loam and it grows in association with Asarum asaroides and Chloranthus japonicus.

The stems of this Gentian are three to six centimetres long, furnished with dark green, broad, ovate, thick leaves, 1½ c.m. long by 1½ c.m. wide at most, the under surface being pinkish-purple. The flowers, borne one to five on the stem, are about 2½ c.m. long by 2 c.m. in diameter, having five lobes, of a fine blue, with a streaked throat. In Japan, G. Zollingerii comes into bloom in April. Although this is still a comparatively rare subject in gardens, it deserves wide notice. *K. Yashiroda, Tonosho, Kyoku, Kagawaken, Japan.*

SOCIETIES.

NATIONAL DAHLIA.

September 11.—The annual show of this special flower Society, which was held in the new Horticultural Hall, Westminster, was very successful. Following immediately after the R.H.S. Show, it must have entailed a deal of anxiety and hard work to have the spaces ready for the exhibitors. But it was done, and the show was ready for the official opening at the appointed hour. The quality of the blooms was very good, and the trade groups and decorative classes were particularly attractive; while the number of exhibitors was as usual in the open classes, there seemed to be an increase of amateurs, which must have been very gratifying to the management. The Joint Dahlia Committee met in the morning and selected the following novelties for trial at Wisley.

Glint.—A Charm Dahlia of orange-scarlet colouring.

Senley.—A velvety-crimson Charm Dahlia.

Lurid.—A glowing scarlet Charm Dahlia.

Claret.—A small Decorative variety of dull pink colour freely lined with claret.

Dora.—A reddish-maroon Charm Dahlia of paler colour at the margins. The above varieties were shown by Messrs. Burrell and Co.

Mrs. A. Brenls.—A medium-sized Decorative variety of bright pinkish-mauve colour. Shown by Messrs. W. Topsvoort, Ltd.

Florence M. Davies.—A large Decorative of orange colour, flushed with rose-pink. Shown by Messrs. W. Treseder, Ltd.

Frau O. Bracht.—A large, clear primrose-coloured Cactus variety.

Katherine Valentine Smith.—A garden Cactus variety of bright mauve colour with a white centre. This and the above variety were shown by Messrs. F. J. Ballego and Sons.

Jamboree.—A large, scarlet-crimson Decorative variety. This and the following were shown by Messrs. J. Stredwick and Son.

Avis Cowdrey.—A large, white Cactus variety.

Laconia.—A large Decorative variety of pale lilac colour, with faint lines of a deeper shade.

Open Classes.

The two classes for Show and Fancy Dahlias were not well filled, although Messrs. W. Treseder, Ltd., the only exhibitors, were awarded the first prize for twenty-four very shapely varieties, which included Harbinger, Standard, Charles Wood, Mrs. W. Slack, Harry Keith, W. Clark and Gracchus. Only Messrs. J. Cheal and Sons showed twelve blooms, and they were awarded the first prize for a moderate exhibit.

The only exhibit of bunches of twelve distinct Cactus Dahlias was a good one by Mr. H. Woolman, whose varieties included Sydney S. Jackson, Patriot, Sydney Jones and Mary Purrier. Mr. Woolman was also alone in the class for twenty-four Cactus Dahlias, shown on boards, and here he had excellent specimens of Yellow Bird, Patriot, Silverhall Park, Edgar S. Jackson, Grasmere and others, which fully deserved the first prize. Messrs. W. Treseder, Ltd., were first with twelve good Cactus varieties, such as Mammoth, G. H. Barlow, Virginia, Elite and Edgar S. Jackson. Mr. Valentine Smith, who was second, showed good examples of Mrs. Gillet, Mary Murray and John Riding. In the class for six blooms of one Cactus Dahlia, Mr. H. Woolman was first with splendid blooms of Fire-dancer, of rich orange-scarlet colour. Mr. J. I. Ingold, Boston, was second. Messrs. J. Cheal and Sons were awarded the first prize for twelve attractive vases of garden Cactus Dahlias. The varieties included Elsie Prior, Edgar Jackson, Miss Eckhart and Guardian.

The Pompon Dahlias were very dainty and fascinating. Messrs. J. Cheal and Sons had the best twelve varieties, showing Glow, Little Beeswing, Little Jim, Mars and Censor, with others equally good. They were also first with twelve excellent Star Dahlias of such sorts as White Star, Gatton Star, Golden Star and Horsham Star. The best twelve Single Dahlias were also shown by Messrs. J. Cheal and Sons, who had Marion, Little Jennie, Mrs. J. F. McLeod and Brilliant, of perfect shape. Earl Beatty (gr. Mr. Barrett), Reigate Priory, who was second in each of the three classes, was first with six exceedingly good Collerette varieties, showing Bonfire, O. M. Courage and Cadet of fine form. Messrs. W. Treseder, Ltd., were second. Messrs. J. Cheal and Sons were the only exhibitors of twelve Collerettes.

First prizes were won by Messrs. J. Cheal and Sons, with six varieties and two vases of good, small Paeony-flowered varieties, and with six vases of small Decoratives, where they had excellent blooms of Mrs. D. Campbell, Lowfield Maroon, Cheerful and Miss Trist. Messrs. W. Treseder, Ltd., who were second, were first in the class for twelve large Decorative varieties, where they showed handsome blooms of El Grande, Halvella, F. T. D. and W. D. Cartwright. Mr. H. Woolman was a good second. Messrs. J. Cheal and Sons were first with a moderate exhibit of six varieties of large Paeony-flowered Dahlias.

The Monro Challenge Cup induced very good competition, although all the blooms that were staged were not exactly "suitable for market purposes." Some were decidedly too large and set on unduly long and thick stalks. But Mr. J. Emberson, who was again first, set up an admirable exhibit of twelve varieties of ideal market flowers. He included Mrs. Linford, Feodora, Cheal's Pink, Reg. Godfrey, Snowdrift and Crimson Flag. Mr. J. B. Riding, who was second, had good and typical blooms of E. Liedling, Blanche Rowland and Persis.

Amateurs' Classes.

Two very good exhibits of Show and Fancy Dahlias were staged. Mr. H. Langdon, Shenfield, Middlesex, who was first, included Miss Browning, Merlin, Standard, Mrs. Langtry and Henry Clark. Mrs. T. Wright, Winkfield, was second. Mr. A. N. Clark, Bromley, was an easy first in the class for six varieties, and he included Tom Jones, Mt. Blanc and J. B. Cambe. The Rt. Hon. W. Dudley Ward, Sunbury, was an easy first with six varieties of Cactus Dahlias, where he included Edgar S. Jackson, M. Purrier, J. Emberson and Abbotsford, of considerable merit. He was also first for six varieties in bunches of three's, and here he showed Torchlight, Ethel and Canary, of high quality. Dr. C. J. Welch, Sandy, was second. Mr. W. G. Cramp had twelve excellent first prize Cactus blooms on boards, and his very best were Yellow Bird, Edgar S. Jackson and Mammoth. Mr. Valentine Smith was second. Mr. F. Chennells, Wheathampstead, was first with three blooms each of four varieties, with splendid examples of Champion, Valour, Mrs. W. Jackson and Rev. Y. Weaver. Mr. W. G. Cramp was a good second. Mr. J. I. Ingold had the best six varieties. As in the open classes, the Pompon Dahlias were of high quality. The competition was very good in the class for twelve varieties, where Mr. C. Luckin, who was first, included Daisy, Glow, Madeline and Johnnie. Mr. A. N. Clark was a good second. Mrs. T. Wright was first in the class for six varieties, and she included perfect examples of Cyril, Darkest of All, Glow and Princess. Mrs. Fisher was second. Earl Beatty, showing Marcel, Sunray and Columbine, of perfect shape, was first with twelve Single Dahlias, and Mr. A. Brown, who had Klondyke and Grace Graham of excellent type, was first in the class for six Singles. Earl Beatty was the most successful exhibitor of Star Dahlias, his six good varieties including Surrey Star, Haslemere Star and Gatton Star. Mr. C. Luckin was second. Mrs. Oakley Fisher had the best three vases.

The Decorative Dahlias were of very good quality. The Rt. Hon. Dudley Ward was first with nine handsome vases. Mr. G. F. Drayson, Buckhurst Hill, showing beautiful blooms of Elite, Glory, Sola Mio, W. D. Cartwright and Mabel Lawrence, was first in the class for twelve large varieties, and, with equally good blooms of Golden Fleece and Marmion, was also first with four vases. Mr. C. Luckin was first with six varieties of small Decoratives and miniature Paeony-flowered varieties arranged with suitable foliage. Mr. Valentine Smith had the best large Paeony-flowered varieties.

The Decorative classes were well filled, and included many artistic arrangements. In the open classes, Mr. J. Emberson was first with a handsome vase of Dahlias and foliage, and Mr. A. J. Cobb was second. Mr. C. Luckin had the best of many bowls of Dahlias, and Mr. Cobb was again a good second. Of the seven dinner table decorations of Star Dahlias, the best was arranged by Mrs. E. J. Cooper, Warlingham, who used Epsom Star very effectively. Miss Woolven had the first prize table of Mignon Dahlias, and Mrs. Courtney Page was first with a pretty table in the class for other types of Dahlias. There were many attractive exhibits of three bowls of Dahlias suitable for sideboard decoration, and Mr. D. B. Crane was first, with Mr. J. Emberson second. In the ladies' classes, Miss Woolven was first with a splendid basket of scarlet and red Dahlias and autumn foliage, with a handsome vase, and with a beautiful bowl of Dahlias.

NON-COMPETITIVE EXHIBITS.

The trade growers of Dahlias were greatly in evidence, and the walls of the hall were lined with many striking groups; it is a great pity that it was not found convenient to remove the background material between the pillars for, had this been done, a much better general effect would have been obtained.

One of the most striking groups of Dahlias was that set up by Messrs. Dobbie and Co., who made special features of Paeony-flowered and Collerette sorts, staging many grand representatives of both these classes; prominent among the former were Alexandra, glowing orange-red; Doreen, rich pink; Midas, primrose; Dazzler, scarlet; Chelsea and Lilian C. Page, while outstanding Collerette Dahlias were Scarlet Tuskar, Trossachs, a grand white; Glen Scannox, crimson-scarlet, cream collar; Betty, Lochnagar, deep velvety-crimson, white-flecked collar; Scarlet Queen, Tuskar, Arran and Vera. A basket of grand blooms of the rich scarlet-crimson Reginald Godfrey was set in the centre of the group, while other striking sorts included Seafield, Jersey Beauty, the brilliant Ullswater, White King, Feodora, Mrs. H. C. Drusselhuys, Golden Queen and Andreas Hofer.

Messrs. H. J. Jones and Mr. H. Woolman shared the wall space at the end of the hall, and both set up very handsome groups, that arranged by the former firm being nicely finished off with Maidenhair Fern and containing grand pillars of such large-flowered Decorative sorts as Canberra, Red Emperor, Mabel Lawrence, Rayonnante, Polar Bear, Hera and W. D. Cartwright. There were masses of blooms of Reginald Godfrey, Cavalier, Jersey Beauty, Mrs. C. H. Drusselhuys, Ferdinand de Bois, Homeric and Tommy Atkins, while among the Pompon Dahlias, Fashion was worthy of note.

In Mr. H. Woolman's group, the large sheaves of W. D. Cartwright, Grace Curling, Rosa Taylor, Trentonian, Jack Hobbs, Pride of San Francisco (very fine), E. Vanderveer; and among Cactus sorts, Harry Strutt, rich crimson-scarlet; Southport, yellow, shaded bronze; and E. J. Robins, called forth much admiration, while he also showed Ullswater, Pink Pearl, Shining Sun, Toplight, Rapallo and such dwarf bedding sorts as Mrs. W. Clarke, Amber Gem, Lady Aileen and Dinkie, extremely well.

The exhibit set up by Messrs. J. Cheal and Sons was a trifle flat, although there were good baskets of Mignon varieties, notably Daphne, dark velvety crimson; Peter Pan, scarlet; Lady Aileen, Blanche, Daffodil and Kathleen. Other Dahlias noted in this group were King Harold, Leslie Hancock, Queenie, President Wilson, Joyce Goddard and Andreas Hofer.

Messrs. Carter Page and Co., Ltd., staged grand blooms of such large-flowered Decorative sorts as Jersey Beauty, Prestige, The Prince, a fine deep scarlet; H. B. May, Menny Carlee, a good white; Fireman, Trentonian and Canberra, while their outstanding Cactus varieties were La Lorraine, Trophy, Andreas Hofer, Peerless, Harry Strutt, Joyce Goddard and Johannesberg.

Mr. J. B. Riding showed large-flowered Decorative sorts chiefly, among his best being Starlight, Berengaria, Raphael, Neptune, Grace Curling, Marmion, Hera, The Nigger W. D. Cartwright, El Granada and Carnival; his group was lined in front with various choice Paeony-flowered and Mignon sorts.

As usual, the Dutch Dahlia Society was responsible for the setting up of a collection of choice novelties from Holland, chiefly large-flowered Decorative Dahlias. They included Mr. A. Breuls, rich rose-pink, shading paler; Pucella, white, with incurving, curled petals; Luxor, deep velvety crimson; Chemar's Masterpiece, lavender-rose, with large, curled petals; Edegem, rich primrose; Saturnus, light brick colour; White Wonder, Réve d'Or, after the colouring of Prestige; Royal Velvet, rich deep scarlet, very fine, and Royal Pink. The only Dutch firm to stage a group was Messrs. J. G. Ballego and Sons, who showed some striking large-flowered Decorative sorts. Among these we noted Katherine Valentine Smith, pink, white centre; Schwerin's Wahl, smoky-bisquit; Frau O. Bracht, enormous, pale primrose; and Jane Cowl, light yellow, tinted copper.

Large-flowered Decorative and Cactus varieties constituted the chief features in the exbihit set up by Messrs. Jarman and Co., of the former Amein Ra, Menin, Berengaria, Mrs. Stuart Sandeman, Josephine Adair, a good primrose; Trentonian, richly-coloured; H. B. May and Evelyn Hancock being the most striking. Good Cactus sorts included A. E. Amos, Peerless, J. T. Cowan, Ballet Girl, Harry Strutt and J. Emberson. They also showed Rapallo and Falstaff in grand form.

The notable sorts in the extensive collection arranged by Messrs. H. Langridge and Co. were Mammoth, Golden Queen, Cardinal, Jersey Beauty, Brentwood Yellow, Persis, Leslie Hancock, Orange Boven and Couldson; Mr. Charles Turner included good blooms of several large-flowered Decorative and Cactus sorts in his small collection, while in the representative group set up by Mr. S. J. Goodliffe, specially noted sorts were Mrs. A. Harvey, Tangerine, Joan Fife, John, Glory, Mrs. C. H. Drusselhuys, Rapallo and Joyce Goddard.

Messrs. James Stredwick and Co., as usual, staged grand specimen blooms of first-class large-flowered Decorative sorts chiefly, included among which were R. Findlay, rich primrose; Flying Officer Waghorn, large, curled petals, glowing velvety-red, paler on the reverse, with a Plum sheen; Grace Curling, Daily Mail, Carmania and Menin.

In his attractively arranged group, Mr. W. Yandell showed Mabel Lawrence, Golden Sun, Red Emperor, Yellow Bird, Border Perfection, Rapallo, Locarno and Champion, in good condition, while notable sorts in the extensive and representative collection set up by Mr. J. T. West were Jersey Beauty, Titan, Berengaria, Mabel Lawrence, very fine; Mr. John Emberson, White King, Blanch Rowland, Negress, Tiny, very dainty; Rapallo and Ullswater. He also showed numerous Pompon varieties.

The King's Acre Nurseries, Ltd., had a nicely arranged group in which were striking pillars of Golden Sun, Red Emperor, Hera, Andreas Hofer and The Clown. Jersey Beauty, Joyce Goddard and Dempsey were shown well, while Pompon varieties included Fashion, Dora, Gretchley Heine and Titan.

BRADFORD GARDENERS'.

Members of the Bradford and District Gardeners' Association spent a most enjoyable afternoon on September 7, when, by the kind invitation of Mr. J. Slater, they paid a visit to his nurseries at Chapel Hill, Skipton. The party first visited his shop at Belmont Bridge where was a great display of Gladioli, grown at Chapel Hill. On arrival at the nurseries they were escorted by Mr. Slater and his two sons, who spared no efforts to interest and instruct the members. The nurseries were wonderfully clean and the stock particularly healthy. After two hours spent in the nurseries, the members adjourned for tea, after which, on the proposal of Mr. Kelk, of Calverley, Mr. Slater was heartily thanked for his kindness, and in reply said it had been a great pleasure to him to receive a visit from the Bradford and District Gardeners, and he hoped to see them again when he would arrange for visiting other places of note in and about Skipton. Mr. Slater's sons both made delightful little speeches, and wished the Association every success.

ROYAL CALEDONIAN HORTICULTURAL.

At a meeting of this Society, held at Edinburgh recently, and presided over by Mr. J. T. Jeffrey, Superintendent of Parks, the members were addressed by Mr. A. J. Macself, on "Some Post War Developments in British Horticulture." The most important feature, he observed, was the increase of new houses, all with garden space attached. This means that a great proportion of the new horticulturists are novices, and the greatest demand is, therefore, for plants of easy culture, that will thrive and make good without special care or conditions. The families of plants which have shown greatest advances include such free-growing subjects as Lupins, Irises, Gladioli and Delphiniums. Delightful strains of easily grown subjects, such as the Bartley strain of Primula pulverulenta and the Shirley Foxgloves have been evolved by the process of careful selection, and he urged the further pursuit of plant improvement by selection rather than the crossing of strange species to produce hybrids. On the scientific side, the introduction of tar-distillate washes and Potato breeding came under observation, and the hope was expressed that in straining after that which is new we should not permit ourselves to lose grip of that which is essentially good in the old.

On the proposal of Mr. W. Cuthbertson, a vote of thanks was given to Mr. Macself.

The exhibits included hybrid Coltness Dahlias by Mr. Stewart Sim, The Lodge, Granton House, and Mr. S. J. Cook, Murrayfield, and two large Cauliflowers, each measuring about eighteen inches in diameter, by Mr. Cadell, Brae Lodge, Murrayfield.

Awards were made in the competitive classes as follows:—Two vases of Dahlias, first, Mr. W. Crighton, Mortonhall; second, Mr. S. J. Cook. French Beans, first, Mr. W. G. Stott; second, Mr. R. B. White, both of Murrayfield.

The annual two days' show of this Society was opened on September 11, in the Waverley Market, Edinburgh, by the Countess of Haddington. The schedule contained 239 classes, and the entries in the competitive classes numbered about 2,000, which is slightly in excess of last year's figures, while 1,000 entries were received in connection with the annual exhibition of the National Allotment Federation, which formed an interesting adjunct to the more important event.

A spell of fine weather had been experienced since the advent of September, and its influence was reflected in the quality of the exhibits, and particularly in the colours of the cut flowers. Except in a few instances, the classes were well filled and competition generally was keen.

Interest in the show was accentuated this year by the introduction of two new competitions. The Abol Challenge Trophy was offered for the exhibit which demonstrated the greatest advance in plant breeding since the war, and it was awarded to Messrs. Dobbie and Co., Ltd., for their Orchid-flowered Dahlias, of which there was a magnificent display.

The other competition provided the outstanding feature of the Rose section. What is to be known as the John Phillips Memorial Challenge Trophy, value sixty guineas, was offered along with three money prizes, for six bowls of Roses, not more than twelve blooms and not fewer than six varieties. Effective arrangement was specified as a condition, and the bowls provided by the Society were limited to six inches in diameter at the top. Eight firms were represented, and the winner proved to be Mr. R. C. Ferguson, Dunfermline, whose six varieties were Mrs. Henry Bowles, Mrs. Charles Lamplough, Mabel Morse, Lady Pirrie, Earl Haig and Caroline Testout; Messrs. Thomas Smith and Son were second, and Messrs. Austin and McAslan, third.

The Rose classes were well filled, both in the open and in the gardeners' and amateurs' division, and the quality of the blooms showed an improvement on that of last year. Mr. R. C. Ferguson followed up his success in the more important event by securing first place in the class for six decorated baskets, and he also provided the best twelve red Roses. Messrs. Adam and Craigmyle, Aberdeen, were again strong in the class for thirty-six blooms, and they likewise prevailed over Mr. W. Ferguson in the contest for twelve blooms of new varieties, and defeated Messrs. Austin and McAslan in the class for twelve yellow Roses. Mr. W. Ferguson, however, obtained some measure of compensation by his success over the Aberdeen firm in the class for pink Roses. Mrs. Russell, Mearns, scored heavily in the other classes, being first for two baskets, twelve vases, four vases and twenty-four vases of eighteen varieties.

Cut flowers dominated all other sections of the show. Dahlias made an outstanding colour display, and the individual blooms reached a very high level of quality. In the gardeners' and amateurs' section, the class for four vases of Decorative or Paeony-flowered varieties, and also the class for two vases, were strong, notably the prize lots staged by T. P. Cochrane, Esq. (gr. Robert Grant), Roundebush, Boness. The honours in the other classes were shared by Mr. William Heatlie, Galashiels; Mr. John R. Paterson, Schawbank, Alloa; Mr. George Beattie, Dunfermline; and Mr. R. Robertson, Duns.

The Sweet Pea classes were better filled than they had been for many years, and the quality of the flowers was particularly good for so late in the season. Here the competitions had an unexpected result, Mr. J. Grigor, Banff, only securing second place in the various classes in which he entered. Mr. J. B. Campbell, Newport, was first in the class for twelve vases; Mr. R. Barbour, Morpeth, led for six vases; while Mr. J. Darling, Kelso, excelled in four of the single vase classes.

Carnations were comparatively few in numbers and were not seen at their best. Here the chief prizes for perpetual-flowering sorts were won by Mrs. Mitchell (gr. Mr. W. Aitchison), Furnes, Thurston, Innerwick.

Messrs. George Mair and Son, Prestwick, defeated Mr. D. Whitlaw, Laurencekirk, with twenty-four spikes of Gladioli, which included several promising seedlings, and the latter, who was also second to Mr. A. Penman, Kirkcaldy, in the class for twelve spikes, scored in the class for six spikes and in that for Primulinus Gladioli.

Exhibits of herbaceous plants and annuals furnished variety to the show, and the condition of the flowers was much admired. The Scottish Challenge Cup for a display of single and double Chrysanthemums decorated with Ferns, foliage plants or cut foliage, and occupying a table ten feet by five feet, was won by Mr. J. W. Forsyth, Putteridge, Luton; while Mr. J. D. Duncan, Moredun Nursery, secured first prize for eight vases of early-flowering varieties.

Sir A. McInnes Shaw (gr. Mr. J. McKinnon), Ballochmyle, Mauchline, was first for a collection of cut flowers.

The glory of the pot plant section has departed and it was only in exceptional classes that the awards extended beyond a first or second prize. Mr. P. Reid, Kirkcaldy, defeated Mr. W. Galloway, Davidson's Mains, in the competition for stove or greenhouse plants, but the most successful exhibitor was Mrs. Mitchell, Gilmerton, who excelled with two greenhouse plants, exotic Ferns, Zonal Pelargoniums, scented Pelargoniums, two Fuchsias, one Fuchsia, a flowering plant, a Chrysanthemum in flower, and two Heliotropes.

As usual, fruits were a prominent feature, and the entries for Grapes showed a marked increase. The competition for the Thomson Challenge Trophy was confined to the Marquis of Tweeddale (gr. Mr. A. McBean), Yester Gardens, Gifford, and the Earl of Strathmore (gr. Mr. Donald McInnes), Glamis Castle, but the quality of the fruits was not up to the standard of the fruits exhibited at Southport and Glasgow. For the six bunches of not less than four varieties, each scored their highest points with Muscat of Alexandria, and in the end only two points separated the two, the first-named being credited with 43½ points and the latter with 41½. The Glamis vines produced the best Muscats and Black Hamburgh in the class for four bunches and the best bunch judged for bloom. Mrs. Cree (gr. Mr. C. J. Duncan), Kailzie House, led in both classes for Muscat of Alexandria, while Mrs. Thomson (gr. Mr. T. Vallance), Greenfield House, Alloa, was the most successful competitor in the smaller classes. She was first for two bunches of Black Hamburgh, one bunch of Gros Colmar, one bunch of Madresfield Court, and two bunches of the same variety.

The competition for a table containing nine dishes of fruits resulted as follows:—First, Mr. A. McBean; second, Mr. D. Campbell, Thornhill; third, Mr. William Smith, Dunecht, Aberdeen; and the prize-winners for a collection of nine dishes of hardy fruits were, first, Mr. J. W. Donald, Wooden, Kilson; second, Mr. C. Webster.

There were twenty-six classes for Apples, and the exhibits were so numerous that they filled three long tables. It was one of the best displays ever seen at Edinburgh, and the competition was remarkable for the success of Mr. R. Auldjo, gardener at Makerstoun House, Kelso, who scored in fourteen classes, and this fine record was increased by two first prizes in the Pear section and one for Plums.

The high quality of the vegetable exhibits testified to the favourable season combined with good culture. Potatos, Carrots, Onions, Leeks and Tomatos were particularly fine, and in the thirteen classes for Potatos, Alstair Currie, Esq. (gr. Mr. William Redpath), Holylee, Walkerburn, had a splendid record of nine first prizes.

Some forty-two trade exhibits contributed to the success of the show, and the awards were as follows:—

Large Gold Medals.—The Edinburgh Parks Department (ornamental garden); Messrs. C. Engelmann, Ltd. (Carnations); Messrs. Austin and McAslan (vegetables, Gladioli and Roses); Messrs. Dobbie and Co. (Dahlias, Sweet Peas and Roses); and Messrs. Thyne and Son (Dahlias and herbaceous).

Gold Medals.—Messrs. Allwood Bros. (Carnations); Messrs. Ballantyne and Jackson (Dahlias and herbaceous); Messrs. D. and W. Croll (Roses); Messrs. Dickson and Co. (Roses); Mr. John Downie (herbaceous flowers and hardy fruits); Messrs. Fairbairn and Son (Phloxes and Dahlias); Messrs. John Forbes Ltd. (herbaceous); Messrs. Isaac House and Son (Scabious); Messrs. Laird and Dickson (rock plants and alpines); Messrs. S. McGredy and Son (Roses); Messrs. George Mair and Sons (Gladioli); Messrs. Thomas Methven and Sons (rock garden); Mr. M. Rae (Begonias); Mr. Thomas Robertson (Roses); Mr. T. Smith (hardy plants); Messrs. Storrie and Storrie (fruits and flowering plants); and Messrs. W. Wells, junr. (herbaceous).

Silver-Gilt Medals.—Messrs. M. Campbell and Son (Dahlias); Messrs. Oliver and Hunter (herbaceous); Messrs. Young and Thomson (crazy paving and rock garden; and Mr. R. C. Ferguson (Roses).

Silver Medals.—Mr. W. S. Askew (Ferns); Mr. Thomas Jeffrey (alpines and Conifers); Messrs. Kent and Brydon (cut flowers); Mr. R. Lawrie (Begonias); Messrs. Maxwell and Beale (rock garden); Mr. J. Myles (foliage plants); and Messrs. Tillie, Whyte and Benvie (garden furniture).

Bronze Medals.—Messrs. A. Bruce and Son (Chrysanthemums); Misses Horne (rock garden); and Mr. George M'Glashan (Dahlias).

NATIONAL ROSE.

September 13 and 14.—In spite of the continued great drought, the Autumn Show of the National Rose Society will rank as one of the most successful that has been held. The new Horticultural Hall, Westminster, was filled with excellent blooms, and in most of the classes the competition was good. As usual, the large trade groups were a very delightful feature of the show, and they contained masses of particularly good blooms. New Roses are rarely, if ever, especially noteworthy at the Autumn Show, and the present occasion was no exception to the rule, for, while a considerable number were submitted, only three Certificates of Merit were awarded. We understand that no award will be made this year of the Clay Cup or the Cory Cup, as the Council of the Society considered that there was no novelties shown during the year worthy of the awards.

Certificates of Merit.

Golden Dawn.—This we consider to be the best of the novelties. It is a full double H.T. variety of good shape and particularly fragrant. It is stated to have been raised by crossing Elegante with Ethel Somerset. The broad, substantial, recurving petals are of pale yellow colour, lightly flushed on the outsides with the old rose colour found on some of the true Tea Roses. It is of vigorous habit and appears to be a desirable all-purposes variety. Shown by Messrs. D. Prior and Son, Ltd.

D. T. Poulsen.—A robust, dwarf Polyantha Rose of erect habit, recommended as a bedding variety. The semi-double flowers are about two inches across and of glowing, light crimson colour. The foliage is neat and dark green. Shown by Messrs. Wood and Ingram.

James Gibson.—A rich, velvety crimson, fully double H.T. variety of good form. When first fully expanded, the flowers are quite good but the outer petals soon become magenta-coloured around the margins. It is of free, bushy habit, and the foliage is purplish. Shown by Messrs. S. McGredy and Sons.

Other Novelties.

The best of the other Roses were chiefly those which had already received the Certificate of Merit, and while their appearance confirmed the judgment of the Council, there was no present claim to the highest award. Rose Berkeley, McGredy's Scarlet, Lady Leslie and Mrs. C. Aveling are the names of the best of these varieties.

Nurserymen's Section.

The most important class in this section was that which required a representative group of cut Roses, twenty-five feet by four feet, and the exhibits staged in this class constituted the chief decorative feature of the show.

Six groups were staged, and that set up by Messrs. S. McGredy and Son was deservedly awarded the premier place, for it was very tastefully arranged and the blooms were wonderfully brilliant and clean. As a background, there were pillars of Los Angeles, Hortulanus Buddé, McGredy's Ivory, Margaret McGredy, Madame E. Herriot, Frau Karl Druschki, Sir David Davis and Mrs. Henry Morse, while the handsome corner pillars were of Mrs. A. R. Barraclough and Betty Uprichard. The centre basket of Emma Wright, and the smaller ones of Portadown Bedder and Mrs. Sam McGredy, were very charming, while other good sorts were Christine, Norman Lambert, Miss Willmott, Golden Emblem and Mrs. Charles Lamplough, the last named being of exceptional quality.

Messrs. Chaplin Bros., Ltd., were placed second with a very handsome bank of blooms. They had pillars of Girlie, Scarlet Leader, Coral Cluster, Edith Cavell, Alice, Locarno and Elsie Poulsen as a background to a double row of pillars of such good sorts as Mrs. Henry Bowles, Mrs. Charles Lamplough, Windsor, Dame Edith Helen, Los Angeles, Frau Karl Druschki and Waltham Cross. The baskets of W. R. Chaplin, Conqueror, Mrs. Henry Morse and Independence were well placed. Third place in this important class was taken by Mr. J. H. Pemberton, whose pillars of Moonlight, Vanity and Robin Hood at the back, and of Felicia, Mermaid and Cornelia at the front, were very effective. He had charming baskets of Madame Butterfly and K. of K., other well-shown sorts being Mrs. Henry Bowles, Shot Silk, Mrs. Jules Bouché, Fortuna, Bianca and Padre.

Other exhibitors in this class were Mr. Elisha J. Hicks, who had lovely pillars of many good sorts, and grand vases of Betty Uprichard, W. F. Dreer, Dame Edith Helen, Angele Pernet, etc.; Messrs. Benjamin R. Cant and Sons, Ltd., whose chief sorts were Etoile de Hollande, Rev. F. Page Roberts, Padre, Shot Silk, Dame Edith Helen and Mrs. Beatty; and Messrs. Alex. Dickson and Sons, Ltd., who had artistically arranged masses of Mrs. Wemyss Quinn, Flamingo, Canary, Edith Helen Perkins, Madame Butterfly, Hugh Dickson and Dame Edith Helen, and lovely pillars of Lady Pirrie, Swansdown, Mabel Morse and Betty Uprichard.

The charming group set up by Messrs. D. Prior and Son, Ltd., was considered the best of the six exhibits in the class for a representative group of cut Roses, fifteen feet by four feet. The group contained lovely baskets of Mabel Morse, Mrs. Beatty, Christine and Mrs. C. A. van Rossem, and effective pillars of Shot Silk, Kirsten Poulsen, Elsie Poulsen, and Ophelia, other good sorts being Dame Edith Helen and Miss C. E. van Rossem.

Messrs. R. Harkness and Co., who had a very poor position, were a close second, with a grand group in which the chief features were a central basket of grand blooms of Mrs. Charles Lamplough; pillars of Mrs. A. R. Barraclough, K. of K., Lord Charlemont, Los Angeles and Mrs. Henry Morse, and vases of Madame Butterfly, Rufus, Mariposa and Rev. F. Page Roberts.

The Dowty's Rosery exhibit was third, outstanding varieties in it being Ophelia, Hadley, Ariel, Hortulanus Buddé, Mrs. Henry Bowles and Mrs. Herbert Stevens; while Mr. George Prince, whose chief feature was an extensive array of the *Daily Mail* scented Rose, was fourth. The other exhibitors in this class were Messrs. A. J. and C. Allen and Messrs. W. Easlea and Sons, Ltd.

In the class for a representative group of Roses, ten feet by four feet, Mr. John Mattock led with an attractive collection in which prominent sorts were Mabel Morse, Etoile de Hollande, K. of K., Dame Edith Helen, Madame Butterfly, Los Angeles and Mrs. C. A. van Rossem; Messrs. A. Reeves and Co. were second, and Mr. Henry Drew, third, both showing many good sorts excellently arranged.

For five baskets of cut Roses, distinct, Messrs. Wheatcroft Bros. were first, with lovely baskets of Shot Silk, Hortulanus Buddé, The Princess Elizabeth, Los Angeles and Angele Pernet; second, Messrs. Thomas Smith and Sons; while for three baskets, distinct varieties, the premier award went to Mr. E. B. le Grice. For three baskets of Polyantha Roses, distinct, Messrs. D. Prior and Son, Ltd., showing Elsie Poulsen, Kirsten Poulsen and Alice Amos, secured first prize, Mr. E. B. le Grice and Messrs. A. Warner and Son being second and third, respectively.

The exhibits in the class for twenty-four distinct varieties, not less than three or more than nine stems of each, were not up to standard, although several good individual blooms were shown. Messrs. W. Drew and Son were first, Messrs. Henry Morse and Sons, second, and Messrs. Wheatcroft Bros., third.

In the classes for exhibition Roses in boxes, Messrs. Thomas Smith and Sons were first for twenty-four blooms, distinct, their best being Augustus Hartmann, Louis Crette, Margaret McGredy and H. Stanhope; second, Messrs. W. Drew and Son; third, Dowty's Rosery. Mr. Henry Drew led for eighteen blooms, distinct, showing, among others, good examples of Mrs. Henry Bowles, George Dickson and Earl Haig; second, Messrs. R. Harkness and Co.

Messrs. W. Drew and Son showed the best two baskets of exhibition Roses, two varieties, each in a separate basket, his varieties being Mrs. Charles Lamplough and Earl Haig; Messrs. Wheatcroft Bros. were placed second, and Messrs. Thomas Smith and Sons, third.

An interesting feature was the class for five vases of Rose "hips," distinct, those arranged by Mr. George Prince being deservedly adjudged the best, for he had lovely sprays of R. Webbiana, R. Moyesii, the black-fruited R. attaica, R. lucida, and R. Fedtschenkoana. Mr. J. H. Pemberton was placed second, and the Stanway Rose Gardens, Ltd., third.

Amateurs' Classes.

The eight classes for various Roses in baskets induced very good competition and contained many good blooms. Mr. H. Mitchell, Bradford, was first and Mr. H. F. Spicer, Hitchin, second, in the class for a basket of any one variety. Mr. George Marriott, Carlton, Nottingham, had the best of many single baskets of mixed Roses, and Mr. H. Mitchell was a good second. In the similar class for those who do not grow more than five hundred plants the quality was also exceedingly good, and here Mr. Norman Fletcher, Faringdon, Berkshire, was first, and Mr. Walter Martineau, Boxmoor, Hertfordshire, was a close second.

Showing good blooms of Ophelia, Mrs. Oakley Fisher, Sudbury, Middlesex, was first in the class for a basket of Roses open to growers within a radius of ten miles of London Bridge, and Mr. A. N. Rogers, Putney, was second. Mr. Norman Fletcher, Mr. S. E. Tattersall, Orpington, and Mr. T. S. Malcolm, Warlington, won first prizes with good baskets of Roses in the classes for amateurs who grow their own Roses. Miss L. Walke, Cambridge, was the most successful of those who had not previously won a first prize at the Society's show.

The Roses in vases were especially good. Mr. George Marriott, who included Mrs. H. Stevens, Golden Emblem and Hortulanus Buddé, was first in the class for six vases, and Mr. H. R. Darlington was second. Mrs. C. E. Whitcombe, Bewdley, Worcestershire, had the best six vases of rambler Roses, and she included Dainty Bess, Golden Spray and Climbing Mrs. H. Stevens. Miss Tilley, showing Mermaid, K. of K., and Lady Pirrie of considerable beauty, was the first of four exhibitors who grow their own Roses.

There were some very good exhibition Roses in boxes. Mr. G. Speight, Market Harborough, had the best twelve, and he included Mrs. H. Morse, Bessie Chaplin, Coronation, Frau Karl Druschki, Florence Forrester and Mrs. John Laing. Mr. J. N. Hart, Potters Bar, was a good second, and his best blooms were Mrs. A. R. Barraclough, H. T. Machin, Gladys Harkness, Mrs. C. Lamplough and Mrs. F. Dennison. Mr. H. Mitchell was third. Mr. Walter Martineau had six excellent blooms in his first prize board; he included Lemon Queen, Bessie Chaplin and George Dickson. Mrs. C. E. Whitcombe was second. Mr. W. H. Beckett, Bletchley, Mr. T. S. Malcolm and Mr. W. E. Moore, Ickenham, won first prizes with good exhibition Roses. Mr. A. N. Rogers, Putney, was first in the Metropolitan class.

The ladies' artistic classes fully maintained the expected high degree of excellence, and their arrangements were a very attractive feature of the show. In the open section, Mrs. Tisdall was first with a beautiful dinner table of Roselandia and Rosa sericea pteracantha foliage, and Mrs. A. R. Bide was second, with a fascinating table of Angele Pernet. Mrs. Tisdall also won first prize with a bowl of Roselandia, and Mrs. L. R. May was placed second with Madame Buttetfly.

In the amateurs' section there were many very beautiful dinner table decorations of Roses, and the very best was of Roselandia and Rose foliage artistically arranged by Mrs. Courtney Page, Haywards Heath. Miss M. Woolven, East Grinstead, who used Madame Butterfly effectively, was second. Only Miss L. Walker, Hoddesdon, arranged a table in the class for lady members who had not previously won a first prize. Mrs. Courtney Page was first with a handsome bowl of mixed varieties, and Mrs. A. D. Ruff, Sharsbrook, was a good second. Mrs. C. J. Cooper, Warlingham, who used Sylvia and Madame Butterfly very tastefully, had the best vase of Roses, and Mrs. Courtney Page was second.

The Silver-gilt Medals offered for the best blooms were won by Mr. H. Mitchell, with a lovely bloom of Souvenir de Claudius Pernet, in the amateurs' section, and by Messrs. S. McGredy and Sons, with a magnificent bloom of Mrs. C. Lamplough, which was found with many others almost as good in a large stand in their representative group.

NATIONAL CHRYSANTHEMUM.

The first meeting of the Floral Committee of the National Chrysanthemum Society for the ensuing season, held at the R.H.S. Hall, on September 9, was a most successful one, as no fewer than twenty novelties were submitted for judgment. Mr. D. B. Crane was again elected Chairman of the Committee.

The following awards were made :—

First Class Certificates.

Kingcup. II. 1c (Fig. 108). A graceful, reflexing flower of medium to small size and of rich golden-yellow colour. It is free-flowering as shown by the branching sprays exhibited, and it should prove a useful border variety; the height is stated to be four feet. Shown by Mr. H. Shoesmith, junr.

Almeda. II. 1*b*. A flattish flower of good size, as shown in disbudded form. It has broad flowers, and is of clear fawny-bronze colour, but occasional rose shading suggests its descent from Consul.

Winnie Avery. II. 1*b*. A large-flowered variety with rather stiff, broad flowers of good substance. The colour is old-gold with bronze tinting. This and the foregoing variety were shown by Mr. C. T. Kipping, Hillcrest Orchard, Althorne, Essex.

Crimson Focerex. II. 1*b*. A large-flowered early variety of graceful, drooping Japanese form. The colour is rich crimson with an old-gold centre that is formed by the reverse of the smaller central florets. Shown by Mr. J. Barrell, Bridgwater.

UNITED HORTICULTURAL PROVIDENT AND BENEFIT.

Mr. C. H. Curtis presided at the monthly meeting of this Society, held in the R.H.S. Hall. on Monday, September 9. One new member was elected, and one member withdrew £10 6s. 9d. from his lapsed account, while another member withdrew interest amounting to £5 4s. 2d., from his deposit account. The sick-pay for August came to £102 17s. 6d, on the Ordinary side, and to £89 7s. 6d. in the State section, while maternity claims totalled £7.

The sum of £21 0s. 1d. was granted to six members for optical, dental and surgical treatment, and several other cases were considered.

The Secretary reported his attendance at Shrewsbury and Southport Flower Shows, where he was able to distribute leaflets, balance sheets and membership forms; a vote of thanks was accorded the Chairman for his kind assistance at Southport.

TRADE NOTE.

An interesting little booklet dealing with fertilisers for garden and lawn, is the means adopted by Messrs. Joseph Fison and Co., Ltd., Ipswich, of bringing to the notice of customers their special fertilisers for autumn use in renovating lawns, flower borders, etc. As may be expected from this noted firm, the information and instructions contained in the booklet are sound and practical.

ANSWERS TO CORRESPONDENTS.

GARDENERS' NOTICE TO LEAVE.—*C. F. S.* If you are a head gardener and no special arrangement as to notice was made at the time of employment, and there is no local custom to the contrary, you are entitled to a month's notice. The notice need not be stamped.

IRISH YEW TREES.—*T. W. G.* Irish Yew trees would be likely to thrive under the conditions described, provided the salt spray is only occasional. If salt spray is blown to the position fairly regularly, if only during a certain period of the year, it will probably result in the browning of the leaves, and eventually the death of the shoots, more particularly on the windward side. Should the spray be in sufficient volume to allow salt water to drip down to the roots, it is unlikely that the plants will ever establish themselves. As this is a case of proportion, you would be wise to plant a few trees in the position described and watch them carefully for a year or two. Two years should be long enough to prove whether the conditions will be really harmful or not. The fact that the position is well sheltered from wind is to the advantage of the plants.

NAMES OF FRUITS.—*S. H. H.* Apples, 1, Red Victoria; 2, Cardinal.—*Altho.* —Apple James Grieve.—*A. E. Y.* Your Peaches and Nectarines, were all perished upon arrival so that identification was impossible. —*W. B.* Apples, 4, Red Astrachan; 5 and 7, Lord Suffield; 6, Lord Grosvenor; 1, 2 and 3, immature; please send when ripe and fully developed.—*H. F. B.* Apples, 1, Barnack Beauty; 2, Sugar-loaf Pippin; 3, Pear Jargonelle.

PEACH FRUITS SHRIVELLED.—*F. I.* There appears nothing wrong with the treatment of your Humboldt Nectarine, we can only suggest light shading and more liberal treatment to increase the size of the foliage, and give a more natural shade to the fruits. It is possible the stock on which it is worked is the cause of the trouble, and now the tree has got weak, only a season's rest or very light cropping will restore it to health.

PEACH TREE FOLIAGE YELLOW.—*R. G. L.* We found no disease in the leaves sent for examination; they were poor and thin in texture and appeared to be suffering from a lack of nourishment. Although this tree may receive the same treatment, it may be on another stock. Give now ¼lb. of sulphate of iron dissolved in water at the rate of three-quarters-of-an-ounce to five pints of water. See that the tree is fairly moist before applying this, and wash well with clear water. Reduce the crop next year. Make sure you have plenty of lime in your soil. Top-dress the border with good loam and give a good sprinkling of bone-meal, while, during the growing season, mulch well with decayed manure and feed more generously with liquid manure and other stimulants to encourage the tree to make more growth.

VINE NEGLECTED.—*F. Q.* During the winter or early spring months you should thin the growths of your vine, leaving those rods with the most healthy lateral growths on and cutting this season's lateral shoots back to two or three buds. Each rod should be tied to the wall two to three feet apart, and each young growth stopped two leaves beyond the bunch, and all other useless shoots removed except the leaders, which should be allowed to extend as required. By this means and a little careful attention to watering, feeding and syringing on fine evenings, your vine will recover quickly. It is impossible to give you the name from the bunches and leaves sent.

REMARKS.—This week has seen an all-round improvement in the general demand. Produce available is heavy, but it is moving freely. Rather better conditions are ruling in the hothouse fruit department. Although supplies are heavy, and the Grapes, Melons, Peaches and Nectarines are selling better, there are only small price movements recorded; but, on the whole, the market for these commodities may be termed fairly good. In the English Apple market there is some activity, and best Apples, well packed, are selling well, but there are too many second-class fruits coming into the market, which might have been better disposed of nearer home. Pears are plentiful and, on the whole, are selling fairly well. Plum supplies are heavy, but good Victoria, Pond's Seedling, Monarch and Damsons are selling freely. After an upward movement, English Tomatos are again quoted at lower prices, for which increasing arrivals of Jersey Tomatos have been responsible. Cucumbers show little variation from the recent improved price level. Mushrooms are a firm trade in view of the absence of competition from field Mushrooms. The vegetable section shows a tendency to better values, but cooler weather is necessary before cooking becomes popular to a degree that will develop a demand for vegetables. Salads, such as Lettuces and Endive, are scarce and costly. The Potato trade remains steady.

GLASGOW.

Business in the cut flower market continued dull last week and any movement in prices was in a downward direction. Spray Chrysanthemums sold at from 2d. to 6d. per bunch, and disbudded blooms from 6d. to 1s. for 6's, while specials realised 1s. to 1s. 6d. Gladioli were worth 1s. per dozen spikes; Carnations, 1s. to 1s. 9d.; Roses, 1s. 6d. to 2s. 6d.; Lilium speciosum var. rubrum, 3s. 6d.; Richardias, 3s. to 3s. 6d.; Dahlias, 2d. to 5d.; Stocks, 4d. to 6d.; Asters, 2d. to 3d.; Sweet Peas, 1d. to 3d.; Gypsophila paniculata, 9d. to 1s. 9d.; and White Heather, 7d. to 10d.

Plums dominated the fruit market. Victorias were plentiful at 6d. to 9d. per lb. for table fruits, and 2d. to 4d. for cooking, and other varieties averaged 4d. per lb. English Damsons made 4d., and cooking Apples, 2s. to 3s. per sieve. Home-grown Grapes of good quality are in daily supply. Muscats sold at 5s. per lb.; Kippin Grapes, 3s 6d., and ordinary, 2s. Peaches ranged from 6s. to 12s. per dozen.

In the vegetable market, Cucumbers were offered at 4s. per dozen Cauliflowers, 2s. to 3s.; and Lettuces, 1s. to 1s. 6d.; French Beans, 4d. to 6d. per lb.; Tomatos, 4d. to 5d.; and Marrows, 5d. each.

GARDENING APPOINTMENTS.

Mr. S. Wren, for the past four-and-a-half years gardener to Sir GEOFFREY FRY, Bart., Oare House, Marlborough, as gardener to Mrs. CAEMBE, Pain's Hill Park, Cobham, Surrey. [Thanks for donation to R.G.O.F. Box.—EDS.].

Mr. O. J. Smith, for the past four years gardener to H. S. CHOLMEBY, Esq., as gardener to W. E. BULLOCK, Esq. Lulworth, Coventry. [Thanks for 2s. for R.G.O.F. Box.—EDS.].

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 53·8°.

Actual Temperature—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, September 25, 10 a.m. (Greenwich time). Bar. 30·5. Temp. 62°. Weather, Fine.

Stem-rot or Wilt Disease of Carnations.

Although certain cultivators of perpetual-flowering Carnations find little difficulty in maintaining their plants in a rude state of health by following a careful system of cultural conditions, and a regular use of insecticides and fungicides for preventive purposes, there are those who find success hard to obtain because their plants appear always subject to fungus diseases. One of these last, and one of the most insidious, is the Stem-rot, or Wilt Disease of Carnations, but so much light has been thrown upon this scourge by Dr. W. J. Dowson that there is no good reason why the disease should not be prevented from infecting clean stock, or, at least, have its effects reduced to a minimum. It was at the suggestion of Mr. F. J. Chittenden that Dr. Dowson, then at Wisley, undertook an investigation with the object of finding out (1) whether or not the disease occurring in English nurseries is the same as that recorded elsewhere; (2) under what conditions the disease occurs and is spread, and (3) what control measures could be recommended to Carnation growers. After reviewing previous work on Carnation Wilt Disease, Dr. Dowson proceeds* to describe the occurrence and symptoms of the disease in Carnation houses. He found that the trouble was most evident during June, July and August—periods when the average temperature is higher for a longer duration than at any other time of the year—and is most conspicuous on two-year-old or three-year-old plants. It is not uncommon, however, to find Stem-rot or Wilt in younger plants, or even in newly transplanted cuttings, hence the greater need for the discovery of preventive measures, seeing that cuttings and small, rooted plants are the media by which Carnations are usually distributed by the nurserymen. Cultivators who have suffered loss know full well that the symptoms which portend disease are a slow wilting of one shoot after another, with a loss of the vital green colour, until a straw-yellow shade prevails. Then follow a decay of the roots and a softening and rotting condition of the "collar," although Dr. Dowson states that this latter condition is not a constant sign of infection. Discovering that the disease was more prevalent in certain beds of Carnations than in others, Dr. Dowson found that underground moisture induced wetter conditions in the badly affected beds, while experiments showed that the disease was more virulent and fatal in wet soil than in dry, although up to a certain point the "wet" plants made taller growth than the "dry" ones. Deep planting may favour the disease, as plants with the upper portion of their roots exposed are not so liable to attack. Several strains of Fusarium were isolated from diseased tissues, and it was found that F. culmorum is able to produce a Die-back form of disease, and is also capable of producing Stem-rot, but F. herbarum appears to be scarcely less troublesome; it is, moreover, possible to introduce disease through a contaminated water supply. Following his interesting and careful survey of the disease in question, Dr. Dowson suggests that as the three Fusaria concerned —F. culmorum, F. herbarum and F. avenaceum—are widespread, and probably occur in most soils, the best means of control are:—to sterilise all beds, preferably by steam, before planting; by rooting cuttings in sterilised sand; by quarantining all plants received from an outside source; by careful watering so as to avoid splashing the "stopped" plants; and by keeping the temperature of the Carnation houses relatively low through the summer. Finally, Dr. Dowson states that in England, the occasional Wilting of quite young Carnation plants is due to F. culmorum, while the much commoner Die-back of "stopped shoots" is caused both by F. culmorum and F. herbarum, and the more serious Stem-rot or Wilt is due to F. culmorum.

Register of Growers of Certified Strawberry Plants, 1929.—The Ministry of Agriculture and Fisheries has recently issued a Register of the names and addresses of growers whose stocks of Strawberry plants have been examined by the Ministry's Inspectors this season and certified as typical of the variety and reasonably free from rogues. The following eleven varieties only were examined:—Bedford Champion, Jucunda (Amazone), Leader (Kentish Favourite), Madame Koci (Princess Juliana), Madame Lefebvre, Oberschlesien, Royal Sovereign (Laxton's King George V), Sir Joseph Paxton, Stirling Castle (Garibaldi), The Duke and The Laxton. The certificates which have been issued relate solely to the purity of the stocks and must in no circumstances be regarded as guarantees of complete freedom from disease, although no stocks which appeared to be obviously unhealthy or lacking in vigour have been certified. There are two classes of certificates: (a) Super Certificates, issued in cases where, in accordance with written undertakings given at the time of application for inspection, growers have retained not more than five runners on each parent plant and have allowed only one young plant to develop on each runner—steps have been taken to ensure that the prescribed restriction of runners and young plants has been observed; (b) Ordinary Certificates, issued in cases where no undertaking has been given to limit the number of young plants allowed to develop on each parent. The certificates are valid only up to April 30, 1930, and growers to whom they have been issued have given undertakings that they will be used only in connection with runners produced in 1929 by the plants actually inspected and certified by the Ministry's Inspectors. Copies of the register may be obtained upon application to the Ministry, 10, Whitehall Place, London, S.W.1.

R.H.S. Examinations, 1930.—The Examinations of the Royal Horticultural Society will be held in 1930 as follows:—Written Examinations: General Examination (Seniors and Juniors), March 12 (entries close January 13, 1930); Teachers' (Preliminary and Advanced), March 22 (entries close January 13, 1930); Scholarship Examination, April 30 (entries close March 31, 1930); and National Diploma (Preliminary and Final), May 3 (entries close February 1, 1930). Practical Examinations: Teachers' Advanced, June 13; N.D.H. Preliminary, June 17 and 18; and N.D.H. Final, June 19 and 20. All entries, except those for the National Diploma in Horticulture, should be made on the form in the syllabus, obtainable from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1.

Iris Society's "Bulletin."—*Bulletin* No. 7 issued by the Iris Society and dated July, 1929, is as valuable a production as those which have preceded it, and not less interesting. Although the total income of the Society was but £230 19s. 10d. in 1928, the Committee spent £128 13s. 0d. on *Bulletins*, but this amount was met in some measure by a donation of £25 and £18 16s. 8d. received from advertisements. We congratulate the Committee and Mr. Dillistone, the Editor, on their enterprise. Mrs. Murrell gives an account of her visits to the Iris gardens of Mr. Sutcliffe Pyman, at Sutton Scotney; of Mr. Bliss, at Morwellham, Devonshire; of Miss Insole, The Court, Llandaff; and of Mr. Pilkington, at Woolton, near Liverpool. New Irises, mostly under number, are described and coveteousness excited thereby. The veteran raiser, Mr. George Yeld, V.M.H., writes very ably of the Siberica sub-section of the genus Iris and, greatly daring, Mr. W. E. Saunders, while discussing the best dozen Irises, concludes that "size is not beauty"—a conclusion with which we are in accord. The Rose and the Iris are compared by Mr. Frank Burton, and Mr. Mills deals with "Irises in Canada." A pleasant description of the Iris Show of 1929, with an account of the functions connected therewith, are given, and Mr. G. G. Whitehead gives advice concerning Iris Susiana.

"The Flowering Plants of South Africa."—No. 33 (Vol. IX, January, 1929) of *The Flowering Plants of South Africa*, recently issued, contains descriptions and coloured plates of Commelina africana, t. 321; Caralluma mammillaris, t. 322; Commelina albescens, t. 323; Piaranthus geminatus, t. 324; Cotyledon cristata, t. 325; Commelina Ecklониana, t. 326; Disperis anthoceras, t. 327; Cotyledon Schonlandii, t. 328; Ixia maculata, t. 329; and Disperis micrantha, t. 330. Commelina africana, found in Cape Province, Orange Free State, Natal and Transvaal, is stated to be free-growing and of scrambling habit, flourishing and rapidly spreading on the rock garden and soon covering itself with its rather attractive, canary-yellow flowers. The inflorescence is peculiar in that it consists of two cymes, one of which bears only one bloom, which matures and falls while the flowers of the other cyme are still in bud. Caralluma mammillaris is closely related to Stapelia, in fact, it was described over one-hundred-and-fifty years ago as Stapelia mammillaris. Twenty-four species of Caralluma are found in South Africa, the genus differing from Stapelia in the structure of the corona; C. mammillaris is described as being difficult of cultivation, as if damaged in any way decay quickly sets in and is followed by the death of the plant. Commelina albescens differs from C. africana in the colour of its flowers, which are pale blue, and in having an inflorescence consisting of a single cyme. It is reported as a serious weed in cultivated land in the region of Pietpotgieters Rust, ranking in this respect second only to Cynodon dactylon, as its fleshy roots, when turned up and exposed by the plough, continue growing. The local name of this species is Kannil Dood. The genus Piaranthus is represented in South Africa by eleven species and was founded by Robert Brown in 1811; it differs from Stapelia and Caralluma in being devoid of an outer corona. Piaranthus geminatus was figured in the *Botanical Magazine* in 1810, t. 1,326; it was first figured in 1796, by Francis Masson. Cotyledon cristata does not appear to possess any decorative merit, although it may be interesting botanically, and the same remarks apply to C. Schonlandii, t. 328, the two species being closely related. Commelina Eckloniana belongs to the same sub-section of the genus as C. africana and C. benghalensis; it has small, rich blue flowers which, if produced in sufficient profusion, should make it of decorative value. The quaint little Orchid, Disperis anthoceros, flowers on the mountains of eastern Transvaal during March; it is a shade lover, being found growing under trees, and has been cultivated successfully at the Botanical Laboratories, Pretoria. The richly-coloured Ixia maculata has long been cultivated in the gardens of this and other European countries. Three of its colour forms are recognised in *Flora Capensis*, while the first illustration of it appeared in Jacquin's *Horti Schoenbrunnensis* in 1797; four years later it was figured in the *Bot. Mag.*, t. 539. Disperis micrantha is a terrestrial Orchid of botanical rather than horticultural value, for its flowers are insignificant. It has, apparently, not been figured previously.

---

* "On the Stem-rot or Wilt-Disease of Carnations," by W. J. Dowson, M.A., D.Sc. *Annals of Applied Biology*, Vol. XVI., No. 2, May, 1929. London: Cambridge University Press, Fetter Lane, E.C.4. Price 12s.

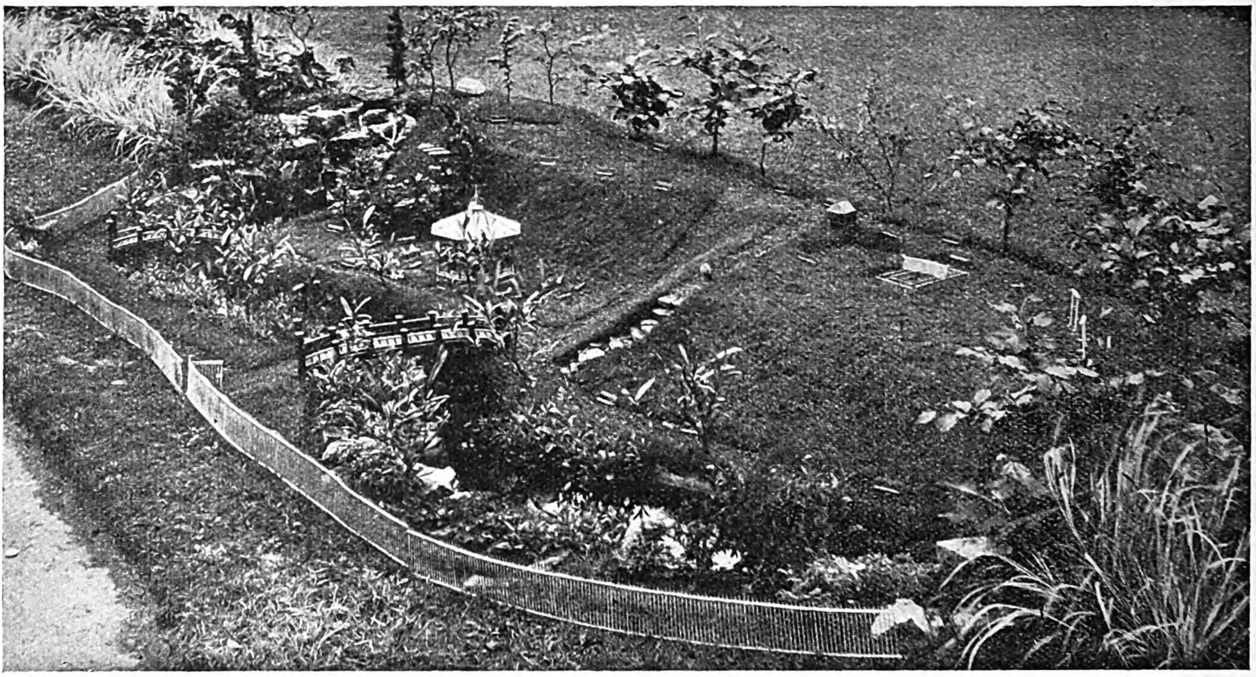

FIG. 115.—A MINIATURE PARK AT DARLINGTON.

Offer of a New Park for Liverpool.—It is announced that Sir James Reynolds, M.P. for the Exchange Division of Liverpool, has written to the Lord Mayor of the City offering his former residence, Dove Park, Woolton, with the gardens and grounds, to the Corporation for the use of the public. The house, which was almost completely destroyed by fire in June, 1921, is situated in fairly extensive and ornamental grounds in Church Road, Woolton, a suburb of Liverpool.

A Miniature Park at Darlington—A "bed" that is at once novel, interesting and instructive has been arranged in South Park, Darlington, by Mr. T. J. Morrison, the Superintendent, and it has attracted a great deal of attention and received favourable comment. It takes the form of a miniature park, complete in detail, (Fig. 115), with stream, waterfall, bridges, rock garden, bandstand, tennis court, children's corner, trees and shrubs, seating accommodation and surrounding fence. At dusk, the whole is illuminated by means of very tiny electric lights. The size of this miniature park is fourteen feet by five-and-a-half feet.

"Hardy and Half-hardy Plants."—In the September issue of *Hardy and Half-hardy Plants* (Vol. I, No. 5), Mr. A. W. Darnell includes descriptions and illustrations of Spartium junceum (coloured), Cynoxylon Nuttallii (syn. Cornus Nuttallii, under which name it is more commonly known); Zenobia pulverulenta, considered by some to be a variety of Zenobia speciosa; Dicentra pusilla, a quaint little alpine species from Japan; Gentiana verna, Oxalis lasiandra whose common name is given as the "Wooly-stamened Shamrock"; Ipomoea bicolor, Incarvillea grandiflora var. brevipes, Herschelia Charpentieriana, a quaint South African Orchid, also known as Disa Charpentieriana; Primula Agleniana, Opuntia humifusa (syn. O. Rafinesquii), Carmichaelia Williamsii, apparently not yet in cultivation; Calceolaria acutifolia, Bidens ferulaefolia (syn. Coreopsis ferulaefolia and Cosmos sulphureus) Sutherlandia frutescens, Aphyllanthes monspeliensis, Lathyrus sativus var. azureus, Delphinium nudicaule, Physaria didymocarpa, Mimulus primuloides and Pellaea Breweri.

Trials of Early-flowering Chrysanthemums.—The National Chrysanthemum Society's Trials of Early-flowering Chrysanthemums, conducted by Mr. Hatch, at his Cookham nursery, will be inspected by a special sub-committee during the afternoon of Tuesday, October 8. Members of the Society and representatives of the Horticultural Press are invited to attend. A train leaves Paddington at 2.5 p.m. for Maidenhead; thence by bus to Cookham.

Sacred Bo Tree Damaged.—Great interest was taken in the trial at Colombo on September 16, before the Lord Chief Justice and two other Judges, of a man who, on July 30, mutilated the famous sacred Bo Tree at Anuradhapura. The Attorney-General, with the Solicitor-General and Crown Council, prosecuted, and two medical specialists gave evidence that the prisoner was of unsound mind, one stating that he imagined himself a special kind of Buddha and mutilated the Bo Tree to prove that he possessed divine powers. The Court unanimously found the prisoner of unsound mind and incapable of making a defence.

Horticultural Education Association.—Under the presidency of Sir William Lobjoit, O.B.E., the twenty-fifth Annual General Meeting and Conference of the Horticultural Education Association was held on September 12 and 13, at the Edinburgh and East of Scotland College of Agriculture, Edinburgh. Upwards of thirty members assembled, representing the County Horticultural Staffs and Research Stations of the British Isles and, among others present, was Mr. H. V. Taylor, Commissioner for Horticulture, Ministry of Agriculture. A most instructive itinerary was carried through during the two days of the Conference. A tour of the Royal Botanic Garden, Edinburgh, was made under the guidance of the Director, Professor Wright-Smith, and the Curator, Mr. R. L. Harrow, during which the remarkable work being done in the propagating department in striking from cuttings all classes of plants by an improved technique, was ably demonstrated by Mr. L. B. Stewart, Assistant Curator. The necessity for the greatest degree of success in this department will be realised when it is stated that 450,000 plants are distributed annually. The Royal Caledonian Horticultural Society's Show in the Waverley Market was visited on the evening of the 12th; this show was a feast of beauty, and southern visitors were much impressed by the evidence of Scottish horticultural skill there displayed. The morning of the second day was devoted to visiting the Scottish Seed-Testing Station and Potato Trial Plots at East Craigs. Mr. T. Anderson received the party, and explained the organisation of the Station and the plots. The careful and painstaking work of the staff of this Station impressed everyone present. The machinery employed in the various processes attracted a good deal of attention; particularly the balances capable of automatically recording the weight of a single Clover seed, and an ingenious small piece of machinery for laying out a known quantity of seeds for the germination test. The work being carried out at this Station among Potatos was particularly instructive, especially in the direction of testing true stocks of standard varieties. It was learned that, in order to produce these stocks free from Virus diseases, tubers of the true stocks are planted twenty yards apart in fields of Turnips. Later in the day, Messrs. Dobbie's seed establishment and nursery grounds were visited under the personal guidance of Mr. William Cuthbertson and members of the firm. Situated, as the trial grounds are, close to the sea and open to all the winds that blow, the stock displayed hardiness and vigour. The Dahlias, at the time of the visit, were especially fine. The tour concluded with a visit to Messrs. Scarlett's remarkable market garden at Inveresk; this establishment is conducted on the most modern lines and with the greatest efficiency. Mr. Robert Scarlett received the party on behalf of his father, Mr. James Scarlett, and mentioned in a short speech of welcome that much of the land had been under cultivation by members of the family for upwards of seventy years. Labour- and time-saving devices are largely employed, and the Skinner system of overhead watering installed in one section of the grounds was seen in operation.

Ostrowskia magnifica.—Mr. S. Arnott writes:—"Many readers will envy Mr. Kingscote the possession of such a noble plant of Ostrowskia magnifica, depicted in the Supplementary Plate in your issue of September 21. This fine species has given much trouble to growers of hardy plants for long years, and it is encouraging to see a photograph of such a grand specimen. In cold districts O. magnifica generally suffers from spring frosts unless protected by a hand-light, and even should it pull through, it is difficult to induce it to flower. In the light of the text on page 217, it is interesting to compare the cultural treatment of the Watermoor House plant with that recommended by Farrer, which you will, perhaps, allow me to quote. He wrote: 'Get large trunks of this as thick as your arm, ram down the surface of a sloping and very deep limy loam-bed in full sun until it is as hard as a threshing-floor. Then, with a crowbar, work a deep enough hole in this to take the trunk, put it in, fill up the hole, stamp it firm, and you need never again have a thought for O. magnifica, which for the rest of your lifetime will continue untended to throw up its stout boles and open its colossal Platycodon-flowers in June.' The note on page 217 awakens fresh hopes in the hearts of those who have tried O. magnifica and have failed to flower it. I have known cherished plants in a garden which did not flower even after six summers, and were reluctantly thrust forth as 'cumberers of the ground.' But where can one obtain the 'trunks as thick as your arm' of Farrer?"

Moray Field Club.—Despite the dull and rainy weather, the last excursion for the season by members of this Club proved a very informative and interesting one, and brought to a close a successful summer series. The Rev. George Birnie, B.D., of Speymouth, the President, led the party and contributed valuable information on the flora of the district visited—Kingston, a few miles from Elgin. The mouth of the Spey—that "regal, rolling river," as John Bright, the Victorian statesman, aptly termed it—was first visited, and here was pointed out the remarkably destructive effects that would be likely to accrue were the Spey to come down in tremendous spate. The picture presented was certainly not conducive to the peace of mind of those living in the locality. Attention was drawn to the vast heaps of small pebbles which are met with at intervals along the shore to Lossiemouth. Of exceptional hardness, these stones make excellent road material. They are of three types—hard granite, whinstone, and what Dr. Machie, late of Elgin, calls Conrack rock. The President then read out a very long list of the flora of the district called Leen, which represents an ancient course of the Spey. An enumeration of the rarer species to be found here will suffice for what the enthusiastic botanist may expect to find when visiting the region. They are: Hypericum hirsutum, Radiola Linoides (syn. R. Millegrana), Peplis Portula, Sedum villosum, Apium inundatum, Oenanthe fistulosa, Hypochoeris glabra, Jasione montana, Anagallis tenella, Veronica Anagallis-aquatica, Rhinanthus major, Galeopsis dubia (syn. G. ochreoleuca), Sparganium simplex, Listera ovata, Orchis carnea, and Catabrosa aquatica. Jasione montana is fairly plentiful on the Leen, the only locality on the east side of Scotland where it has as yet been found. Unfortunately, the weather marred much of the enjoyment of the excursion.

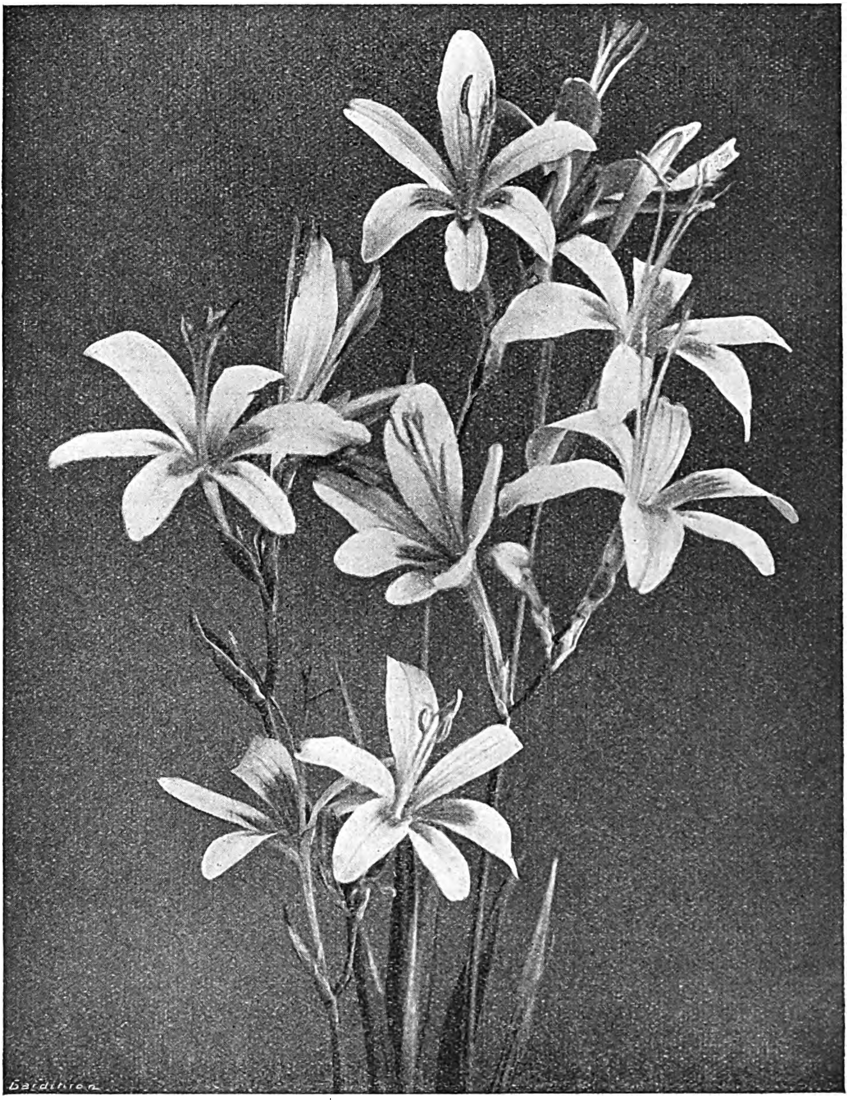

FIG. 116.—LAPEYROUSIA GRANDIFLORA.

R.H.S. Award of Merit, September 19. Flowers bright red, with crimson blotches. Shown by Mr. Amos Perry. (see p. 251).

Appointments for the Ensuing Week.—Tuesday, October 1: Royal Caledonian Society's meeting. Wednesday, October 2: Royal Horticultural Society's Autumn Show (two days); National Carnation and Picotee Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. Thursday, October 3: Bideford and District Horticultural Society's meeting. Friday, October 4: Foots Cray Horticultural Society's Exhibition; Dundee Horticultural Society's meeting; Manchester and North of England Orchid Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Raising Seedling Dahlias.*—This is, perhaps, attended with more interest and pleasure than any other part of the culture of this noble flower. Much has been said and written respecting which sorts are best to save seeds from. I will not attempt to instruct, further than give the system practised by me; which is, to remove all thin, or otherwise inferior blossoms as they appear; for the fewer petals there are, the greater the quantity of seeds, with little or no chance of its producing a good double flower. By this, it will be seen, much ultimate trouble will be saved. In small, select collections, there will not be so much to do on this point; but in large collections there will be many varieties from which it is not desirable to save seed. This accounts for the number of fine seedlings that have been produced by amateurs from small collections; when many, who annually raise thousands, do not produce a good one. It is worthy of remark that those seedlings that take the lead and bloom first seldom, if ever, produce a flower worth preserving; these are from the finest seeds and thinnest blooms; they vegetate first, and keep ahead all through the season, and can easily be distinguished by their tall habit, without side branches; whereas the late small plants, that require nursing to make them bloom before the frost arrives, generally produce the best flowers; it is well known that very few of our best seedlings are ever shown the first season of their blooming. These are from the smallest seeds, and very double flowers. *T. Gard. Chron., September* 30, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Duckyls Park, East Grinstead, Sussex.

Deciduous Calanthes.—Specimens of these graceful, winter-flowering subjects are now growing rapidly, the new pseudo-bulbs being well advanced. To secure the production of strong spikes of good coloured flowers, the plants should be arranged so that each may receive a good share of light, in a position near the glass, and they should not be shaded any more than is necessary to prevent damage to the foliage by the sun. Usually, at this season, a light shading during the middle of the day, is sufficient. Full exposure to the sun during the early morning and late afternoon will help the pseudo-bulbs to finish well. At this stage, with the extra light allowed and the pseudo-bulbs nearing completion, the plants will require plenty of water at the roots each time the soil appears dry, while an occasional watering with weak liquid manure will be beneficial. Any feeding should be discontinued as the flower buds show on the spike, or the colour of the blooms will be affected adversely. Naturally, less water will be required as the foliage ripens, only sufficient being needed to keep the spikes plump and growing. The later-flowering varieties, such as those of the Regnieri section, are much later in growth and require similar treatment to the above later in the season. Calanthes grown in smoky districts open their flowers better during January than if allowed to expand them during November when fogs are so prevalent; therefore, after completing their growths the plants should be retarded by cooler and drier treatment to prevent the flower scapes developing so early.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

The Storage of Hardy Fruits: Apples.—How often it is that Apples and Pears that appeared to be absolutely perfect while growing on the trees in the early autumn have, after a period in store, turned out to be disappointing? In many cases the fruits shrivel, while others become mealy or even rotten when their season of use arrives. There are certain causes for this state of affairs, although the explanations put forward are varied and many. The chief of these are that the fruit store has not been properly constructed; that it is either too dry or too damp; that the aspect is all wrong; or, that the Apples from that particular soil will not keep. The chief cause, however, of shrivelled fruits in store is that the Apples or Pears have been gathered long before they were fit to harvest. No definite date can be given for any particular variety, as the varieties of these two kinds of fruit are influenced in the period of their gathering by season, locality and soil. The weather, too, has a very great influence on the date of gathering, as it may be cold or warm, wet or dry. Apples and Pears should be left on the trees so long as possible. This applies very particularly to the late-keeping varieties, for the longer they hang, the better will they keep in store without shrivelling. Do not be alarmed if a few fruits drop off, for it will be invariably found either that these are injured by birds or wasps, or that they contain grubs. Close observation, however, is necessary; when a sound fruit, on being lifted gently to a horizontal position, parts readily at the junction of the stalk with the spur, that is the best indication of the gathering period. The fruits should always be gathered in dry weather, and, as good storage commences in the orchard, every precaution should be taken to prevent bruising. Clean, galvanised pails are preferable to baskets for gathering the fruits. A thin layer of straw or wood-wool may be placed in the bottom of each vessel, to minimise injury to the fruits so far as possible. Each picker should be provided with a hook to hitch the pail on to the strongest branches at about waist height, so that both hands are free to handle the fruits. Where practicable, the fruits should be graded as they are gathered, all the sound fruits being placed in one vessel and sent direct to the store, while the very small or slightly disfigured fruits are sent to the packing shed for immediate use. Storage means preservation—avoidance of decay. To attain this the fruits must be sound, and free from insect attacks and disease. Careful handling is essential. Nothing is more conducive to disappointment than the storing of late-keeping Apples in a dry, badly ventilated room or loft. Such conditions may suit Pears to a certain degree, but they certainly do not suit Apples. A certain amount of atmospheric moisture, cool conditions, a fairly even temperature of from 35° to 40°, and darkness, are essential to the sound preservation of Apples. Guard against the alternate sweating and drying of the fruits, caused by variation of temperature. Extra ventilation is necessary for Apples during the first three weeks or so in store. This is called the sweating period, for then the fruits exude a greasy substance which is Nature's preservative. After this the store should be kept closed. There are occasions, however, when the air in the fruit store becomes musty or stagnant, and air must be admitted whenever possible, while the external and internal temperatures are about equal. This may be carried out by opening the doors and windows of the store for a few hours on some clear dry evening when the outside temperature is about 35°. The best floor for the fruit store is an earthen one, which rarely needs to be moistened; but where, of necessity, the floor is of wood or concrete, it will be found advantageous to sprinkle the floor occasionally with water to induce damper conditions, and so prevent the shrivelling of the Apple skins. When the Apples are brought to the store they may, with advantage, be piled on top of one another in six or eight tiers. They may be laid on the clean, slatted shelves, or, if desired, on clean Wheat or Barley straw laid across the shelves. This prevents bruising, and allows the air to circulate among the fruits. For that reason paper should not be used, nor is hay or Oat straw desirable, as these become very musty and impart that flavour to the fruits. Treated as recommended, Apples, such as Cox's Orange Pippin, Laxton's Superb, Newton Wonder and Bramley's Seedling, may be kept in perfect condition until the following March or even later. Since the introduction of grease-proof paper for wrapping purposes, it is now possible to prolong the season, by months, of such choice varieties as Cox's Orange Pippin, Laxton's Superb and Blenheim Pippin, by wrapping the individual fruits in this waxed paper. This wrapping paper is impregnated with a mineral oil, and is highly efficacious in preserving the fruits over a long period.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Pot Roses.—Roses grown in pots to produce early flowers should now receive attention with regard to top-dressing or repotting, if necessary. If the soil is in good condition, remove a few inches of the top soil only and apply a top-dressing of good loam, mixed with a liberal supply of bone-meal and wood-ash, after which stand the plants in an open position, plunging them to the pot rims in a bed of coal ashes as a protection against frost; if the plants have made very long shoots it may be wise to shorten these slightly to prevent the bushes being loosened around the collar by strong winds. Many of the Polyantha Roses make excellent subjects for pot culture, and for this purpose they do well on their own roots. Cuttings root readily if inserted in a sheltered border at the present time, or better still, insert four cuttings in a four-inch pot and plunge the same in a trench about an inch below the soil. With attention to potting them on into six-inch pots when they have formed roots, fine plants will be forthcoming for forcing next year.

Potting Bulbs.—Endeavour to procure any bulbs intended for early forcing at an early date, for the best results invariably follow when the bulbs have plenty of time to become thoroughly rooted before forcing takes place.

Sweet Peas.—Where Sweet Peas are grown for flowering under glass during the spring, seeds may be sown now or some time next month to obtain plants for this purpose. Sweet Peas are best raised in small pots for this purpose. Place four or five seeds inside the edge of a pot and germinate them in a cold frame; watch for such enemies as mice, for these are very partial to the seeds, and as a precaution traps should be set for them. During the winter afford the seedlings plenty of air and remove the lights from the frames on all favourable occasions to obtain sturdy growths, which should be the aim of the grower at all times.

Crocuses.—For a cool greenhouse, one cannot imagine anything more beautiful than the many fine varieties of Crocus vernus, when grown in pots or pans. Five or six corms may be grown in a five-inch pot. After potting they should be stood out-of-doors and covered with several inches of fibre or some other suitable material. Here they should remain until they are well rooted, when they may be removed to cold frames which should have the lights removed on all favourable occasions. It is wrong to make any attempt to force them by placing them in heat, for this would result in their going blind.

Browallias.—Plants that have been grown in frames during the summer months should now be placed in the greenhouse, where they should produce a wealth of bloom. Seeds may be sown now to secure plants for flowering next spring.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Vines.—Any root-lifting, root-pruning and additions to borders should now be pushed forward when the weather is favourable. The compost should be prepared in quantity equal to the probable demand; if new turf is used the addition of a fair percentage of bone-meal should set the whole mass in a state of fermentation. If root-lifting is contemplated owing to the compost being exhausted, the spent soil should be removed to make room for fresh compost. Commence at the front of the border when removing the old compost, and take care not to damage the roots as the work proceeds, keeping them moist until the drainage is examined. New turf, grass side downwards, should be placed over the drainage to form the base of the bed, and on this enough compost should be placed to bring it level with the lowermost layer of roots appearing from the undisturbed soil. These roots should be spread out after all faulty or injured parts have been removed with a sharp knife, a little fine soil placed over them, and the whole made firm by treading and beating carefully; further layers may then be added and made firm until the desired level is reached. One-quarter or half the border may be treated in this manner as may be found necessary. The vinery, during this process, may be kept fairly close and moist, or shaded, but if the vines have an abundance of roots in the undisturbed border inside or out, they will not show signs of having been interfered with. As vines always do best before the roots reach the extremity of the space allotted to them, especially when the boundary is formed of cold cement, a turf wall should be built up, allowing about a two-feet run before the new roots enter into it. The space left may be filled with Oak or Beech leaves, if not before, certainly when the vines are started. The gentle warmth from this material will work into the front of the new border and soon encourage the production of new roots, but on no account should this decaying vegetable matter be allowed to remain more than one season.

Peaches.—Peaches, with very few exceptions, have had their fruits gathered, and the next year's crop will greatly depend upon the treatment the trees receive throughout the remainder of the season. Many trees, after being cleared of fruits, only receive half the quantity of water they ought to have; if properly drained, Peach borders may be soaked each week throughout the growing season. Many people think that drought ripens up the wood and foliage, and so adopt a starvation system of treatment; a good set the following season cannot be expected where the borders are not kept moist enough to keep the roots moving through the winter. Trees in all early houses should have been pruned, that is, so far as cutting out superfluous shoots is concerned, but later trees should be dealt with without loss of time. Late trees should be kept extra thin, and all retained growths, especially the leaders, should be left full length. It is not necessary to cut the growths hard back, as the final thinning may be allowed to stand over until the trees are detached from the trellis; the letting in of sufficient light and air is all that is required at present. Borders in which the trees are making too vigorous, or, conversely, insufficient growth, should now be taken in hand. If growth is too strong, root-lifting and relaying in calcareous loam are the best remedies, and the firmer the soil is rammed the better. If growth is too weak, from age or overcropping, the surface soil should be removed well down to the roots and replaced with fresh, enriched compost containing a little soot, old plaster and bone-meal. Manure may be used in very extreme cases, but on no account should it be mixed with the compost, as the weakest trees can be restored by careful mulching, top-dressing and summer feeding. Once the work is finished, tepid water may be given quite freely.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Dwarf Asters.—Among the numerous hardy plants that are available for the embellishment of the garden during late summer and early autumn, none are more welcome than the various forms of Aster Amellus. It is found advisable, especially in moist, retentive soils, to defer the planting of this section until early spring, otherwise there are sure to be losses during the winter months, as they resent root disturbance during the winter. No group of hardy plants is more easily cultivated, yet we often see clumps that have been grown for many years without the least thought of lifting and replanting in rich soil, and, naturally, these have greatly deteriorated. Among the best varieties, for either flower garden decoration or for the reserve garden to provide cut flowers for the house, is King George, which has large heads of bluish-violet flowers, the individual blooms being about three inches across. Variety Ideal is desirable, growing about two feet high and having large, mauve-coloured flowers with a yellow disc. A. Robinsonii is an ideal plant for the front of the border, for its pale blue flowers are produced with the greatest freedom. A. Frickartii is taller than many of the section, growing about three feet high. It flowers with the greatest freedom and is an acquisition to this section. It is of Continental origin, and is stated to be a hybrid of A. Thomsonii and A. Amellus. The colour is of a pleasing lavender. Beauty of Ronsdorf is a charming, compact-growing variety, with lilac-pink flowers. Variety Rudolph Goethe is a very free-flowering plant of upright, wiry habit, bearing large, lavender-blue flowers about three inches in diameter. A. Thomsonii should be included, as it continues to bloom for a very long period, from the end of July onwards. Perle Rose is a dwarf, sturdy, free-flowering variety with mauve flowers shaded pale rose-pink. Variety superbus, growing about two feet high, has flowers of a rich lavender-blue, and will be found a useful variety for many purposes. Variety Sonia, of recent introduction, is an acquisition to the section.

Hardy Cyclamens.—These charming plants are very interesting and attractive when in bloom. At the time of writing, a large colony of the autumn-flowering C. neapolitanum, under the shade of a Conifer, is attracting a great deal of attention. The leaves of this species are Ivy-shaped, and it is at times sent out under the name of C. hederaefolium. It forms large corms, from which spring a multitude of beautiful flowers in varying shades of pink and white, before its foliage begins to appear. All the hardy species are easily established and love the shade of trees and shrubs, where, if the soil is well prepared for their reception, they will give satisfaction for many years. A rich, friable soil with a little lime-rubble added, suits them admirably, with an annual top-dressing of decayed vegetable matter. Seeds are the usual means of propagation; these are freely produced and germinate readily if sown so soon as ripe. Large collected corms are slow in establishing themselves, and should be left undisturbed for at least two years. C. Atkinsii, a hybrid of the Coum section, has flowers a little larger than the type, varying in colour from pale pink to nearly crimson. C. coum is welcome during the dark days of winter and early spring, and should have a warm, sheltered nook in the rock garden, where its flowers can be protected from the winter storms.

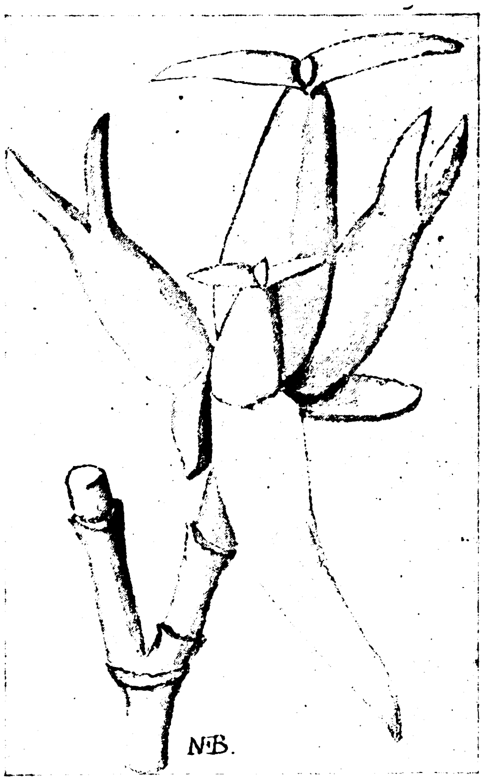

FIG. 117.—MITROPHYLLUM PROXIMUM, SCHWANT.

Branch of type plant when first imported, showing a terminal cluster of growths; natural size.

(see p. 248.)

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Spring Cabbages.—When the plants are large enough, these should be planted at once. If the ground is dry, water it well before planting. The largest plants should be taken from the seed-bed first, so as to give the smaller ones more room for development. Dust around the plants with soot after planting to ward off slugs.

Cauliflowers.—Seedlings intended for early spring planting should, so soon as they are fit to handle, be pricked out into frames and kept perfectly hardy by giving plenty of air during the day. Shade the young plants for a few days after pricking them out.

Lettuces.—So soon as the recently-sown plants are fit to handle, prick them out into frames. These will turn in early in spring for cutting; All the Year Round and Felton King are two fine varieties for frame culture, and withstand winter cold and dampness fairly well.

Turnips.—Late-sown Turnips are now ready for thinning, which operation should be done carefully. Encourage quick growth by working the Dutch hoe between the lines to keep the surface soil open and weeds in check.

Endive.—Additional plantings of Endive may be made as ground and frames become vacant.

Maize.—During dry spells, Maize should have ample water supplied to the roots, otherwise the cobs will fail to swell satisfactorily; cut the cobs before the seeds become hard and dry.

Potatos.—Late Potatos are now ready for lifting. The crop suffered during the dry weather, and the haulm died off quickly through lack of moisture at the roots, and although the tubers may not be up to standard size, it is better to lift them now than to wait until the ground becomes wet again, when disease and decay may set in.

Rhubarb.—Good stools of Rhubarb should be selected for forcing, and the roots lifted and exposed.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq. Rosemount, Monkton, Ayrshire.

Vegetables.—Earth up Celery when the soil and plants are dry, dusting them with air-slaked lime, or soot, or both, as the work proceeds. If rust is in evidence on the plants, flowers of sulphur should be mixed with the lime and soot. Encourage the growth of late Kale, Broccoli, Spinach and Onions by frequent use of the Dutch hoe during dry weather. Fill frames with Lettuces and Cauliflowers for spring planting, the soil used being sandy and of a rather poor quality, as slow, sturdy growth is necessary during the winter months. Use shallow frames or, alternatively, raise the bed well up to the glass and see that the lights are water-tight.

Cuttings.—Cuttings of Pentstemons, Calceolarias, Violas, Pansies and all plants of a like nature should now be inserted in beds of sandy soil. Animal or other manures should not be present in the cutting bed, equal parts of mould and rough sand added to the loam being ideal, with a layer of pure sand on the surface. The bed should be rather firm and the cuttings put in so that the general surface is not broken. Short cuttings are best in all cases, and they should not be inserted deeply. As in former cases, white-wash the glass so that the frame may be kept closed during the day, despite the sun, and admit air at night, or remove the lights should the weather be fine.

Protecting Dahlias, etc.—Beds of Dahlias and early-flowering Chrysanthemums should have erections placed over them to support blinds or mats, at short notice, if frost comes. Continue to house Chrysanthemums which are well set, but in cases where the buds have not appeared they are much better out-of-doors during the day. Before housing them spray all Chrysanthemum plants with lime-sulphur or sulphide of potassium to check the ravages of mildew and rust after housing, but allow the foliage to dry out-of-doors. Advantage should be taken of all dry spells to clear away all weeds, dead leaves, etc., and herbaceous plants should be cleared of their flowering stems, after which the ground should be well stirred with the hoe to admit air to the soil.

ALPINE GARDEN.

OXALIS VALDIVIENSIS.

A yellow-flowered Oxalis which has been growing in my garden for many years and whose name has hitherto been in doubt, has been identified by a botanical correspondent as O. valdiviensis. This species, which came from its native Chili in 1862, is described in some garden dictionaries as a herbaceous greenhouse perennial. Here we have always regarded it as a hardy biennial, perhaps wrongly, since individual plants will often survive a second or third season, provided they do not "bloom themselves to death." The thick, fleshy root of O. valdiviensis produces several crowns, from each of which arises a compact and upright tuft of leaves and flowering stems. These may be anything from three to fifteen inches in height, according to soil and situation. The trifoliate leaves, which average over one inch across, are a bright, cheerful green, and the flowers, which are borne in a two-branched head at the tips of their stately stalks, have the grace of some choice Primula. These blossoms, nearly as broad as a shilling on a well-grown plant, are a peculiarly lustrous yellow. They are distinctly rayed on the reverse with crimson, and the broad petals overlap in a well-rounded corolla of good substance.

O. valdiviensis is undoubtedly perfectly hardy in a well-drained, gritty loam, but it has a strange partiality for particular soils. Here, for example, it naturalises so abundantly that it often has to be weeded out, yet in a neighbour's garden it refuses to prosper under apparently similar conditions. But, vigorous as it is with me, O. valdiviensis is never a menace, even among rock plants, for, unlike some of its relations, it does not run underground or misbehave in any other aggressive manner. It is a plant that blooms with amazing prolificacy from April to November, and one that we find most useful as a temporary covering for bare soil between Heaths, dwarf Rhododendrons or any other recently-planted things. Although a sun-lover, this charming plant crops up in all manner of places here, and it is utterly indifferent to drought. So immune is it, indeed, from the troubles which beset so many subjects that I look upon it as one of the permanent furnishings of the garden which asks no attention and entails no expense. *A. T. J.*

FLOWER GARDEN.

ECHINOCYSTIS LOBATA.

The recent account of this North American Cucurbitaceous climber by T. H. Everett, of New York (*Gard. Chron.*, September 14, p. 209) has enlightened me, for the plant has been growing here for the first time this summer, and I was becoming puzzled as to its botanic name. The description he gives leaves me no longer in doubt as to its identity. Apparently, it is little known or grown in this country. It is not mentioned in Nicholson's *Dictionary of Gardening*, but receives notice in the *Century Supplement* to this work.

The seeds were given me by one of my maids. Her brother, who lives at Edmonton, in Canada, brought a quantity with him when on a visit to his old Cumberland home during the spring of last year. He informed his family that the plant is commonly grown out there to cover dwellings in summer, for the sake of coolness.

The seeds did not come into my hands until well into June of last year. Imagining early germination in heat to be necessary in order to give the plant a chance of making much of a display in our comparatively cool summer, I did not anticipate great results from a few seeds sown at the base of a south wall. As it happened, there was no germination at all, and my interest in the plant waned. Great was my surprise this spring in finding the seedlings coming up, in spite of the fact that the ground had in the meantime been dug over. Why these seeds failed to germinate the previous summer is not clear to me. My maid tells me that at her home, where the plant has now been growing for two summers, self-sown seedlings have appeared here and there. Evidently Echinocystis can readily raise itself from seeds in this climate without any artificial aid. Possibly it may prove itself somewhat of a nuisance by coming up where it is not wanted, but being an annual it can easily be weeded out.

The plant has shown itself to be a rampant climber with me and a wonderful clinger, its abundant and sensitive tendrils attaching themselves even to projecting bits of mortar. It has this summer scaled a ten foot wall and descended half way down the other (north) side. As I write, in mid-September, it is now out of flower and is ripening its seeds. These are dark brown in colour, somewhat of the size and shape of Marrow seeds, and four only are contained in each prickly, pendent fruit.

Although the individual staminate (male) flowers are tiny and very modestly coloured, their great abundance imparts a creamy, foam-like appearance to the plant. The tender green of the clean-cut foliage is distinctly refreshing to the eye. Both Mr. Everett and the *Dictionary Supplement* fail to mention one attraction, namely, the pervading fragrance of its flowers. This is quite noticeable when one is in the vicinity of the plant.

Echinocystis lobata can be recommended for covering rapidly any bare wall, unsightly erection, or rubbish heap. Care should be exercised in introducing it among choicer and less vigorous subjects, for from my experience it might be termed a smotherer, and therefore needs keeping apart. *J. Parkin, Blaithwaite, Wigton, Cumberland.*

IPOMOEAS.

The Ipomoeas are quick-growing climbing plants of high decorative value which an older generation treated entirely as stove plants and older text-books refer to them as the "Convolvuli of the stove." But although mostly of tropical or sub-tropical origin, I. purpurea and its numerous forms are admirably suited to outdoor cultivation, and in a season like the present one their brilliant flowers of delicate texture make a wonderfully effective display.

The plants are easily raised from seeds in the spring and if the seedlings are grown on in five-inch pots and planted out at the beginning of June they make rapid growth and continue to give a succession of flowers until the cold nights of autumn arrest growth. The best position is the base of a wall or pillar, fully exposed to the sun, but sheltered from the prevailing winds. *A. M. W.*

ORCHID NOTES AND GLEANINGS.

MASDEVALLIAS.

Where a varied collection of these interesting and free-flowering Orchids is grown, specimens may be had in flower practically the whole year round. Many of the strong-growing, brilliantly coloured kinds, such as M. coccinea, M. Veitchiana and varieties that have flowered during the summer months, and were not repotted in the spring, may require some attention at the roots, and now is a suitable time to repot any plants that are in need of larger receptacles or fresh compost, as fresh root action is now commencing and the plants should quickly become re-established if carefully repotted at this season.

Specimens that are overgrown and have lost their central leaves should be broken up and all decayed compost, dead roots and leafless rhizomes removed. Each portion may be potted separately in very small pots or pans, where they should establish themselves readily and be suitable for remaking into specimens early next spring. Healthy, robust plants that need larger receptacles may be potted on without great disturbance, provided the rooting material is in good condition; if it is not, remove all sour and decayed portions and renew with fresh material carefully worked in among and around the fleshy roots. Use well-drained pots, or deep pans for the robust growers, and a compost consisting of three parts Osmunda fibre, cut moderately fine, and one part chopped Sphagnum-moss, adding crushed crocks or broken charcoal to keep it open; a little extra Sphagnum-moss may be used for finishing off the surface.

The smaller-growing kinds, such as M. simula, M. triaristella, M. trichaete, M. ludibunda, and the free-flowering, sensitive-lipped species, M. muscosa, are best accommodated in small pans or baskets, which may be suspended or placed in a position near the roof glass. The dwarf kinds require only a small quantity of compost, and this should be made moderately firm, with the base of the plant resting on the top of the compost, just below the pan rim, allowing ample room for watering during the growing season, when established plants require copious supplies each time the soil appears dry.

After repotting, only small quantities of water should be given—just enough to moisten the compost; encourage root action by keeping the surroundings and pot moist by frequent syringings and damping during favourable weather until the roots are seen working through the fresh soil, when larger quantities of water may be given each time the compost requires moisture. Care should be taken, however, to avoid an excess of moisture at the roots or in the atmosphere during dull, cold weather and the short days of winter, or the unsightly black spot disease may soon appear on the foliage; also the leaves will begin to fall. If new leaves turn yellow and begin to fall, it is a sure sign of bad root action, and steps should be taken at once, by removing and renewing the compost and growing the plants in small receptacles until they have recovered their vigour. Any delay at this stage may lead to sickly plants for a long time, or result in their total loss.

Most of the Masdevallias thrive well in a shady part of the Odontoglossum house, where they are not subject to cold draughts; in cold districts the Chimerae Masdevallias are best grown at the cool end of the intermediate house during the winter months, and are best accommodated in baskets without any hard drainage material being used, to allow the flower spikes, which are often produced in a downward direction, to push through the openings in the baskets. The distinct, long, metallic-leaved species, M. deorsa, is seen to the best advantage when grown on a block of wood or on a teak-wood raft suspended from the roof. *W. G.*

INDOOR PLANTS.

RUSSELIA JUNCEA.

Russelias, of which there are four species, and one, R. Lemoinei, of hybrid origin, are natives of Mexico, and have been in cultivation at different times for a century. They are members of the Fig-wort Order, Scrophulariaceae, but are not so frequently grown outside botanical collections as formerly.

The three-feet-long, arching growth of Russelia juncea make it an admirable subject for growing in baskets suspended from the roof—a pleasing system adopted advantageously with plants of pendant growth, and which affords a change in the embellishment of conservatory and greenhouse throughout all seasons of the year.

Cultivation presents no difficulties. Cuttings are easily rooted in spring, and these, when well rooted, should be placed in the baskets, in a compost chiefly of sandy loam, and kept growing in genial warmth, until well developed and established for their removal to cooler quarters, as the season advances.

The light red flowers, borne upon the branchlets, are not produced profusely, although it is seldom from midsummer onwards over a lengthy period that the plant is not in flower.

An excellent use I observed made of this subject, was in a tropical public garden abroad. A long, narrow border was planted entirely with it to serve as a partition hedge; there were few flowers open at the time, but the characteristic deep green, Rush-like growth, justified its use for this purpose. *Frederick Gooch.*

LILIUM MARTAGON VAR. ALBUM.

IN the absence of any definite record of the beginning of the white-flowered variety of the Martagon Lily, it has been generally assumed to have had a garden origin. There is no evidence of this, however, nor is there any particular reason to suppose that the cultivation of plants encourages the production of albino forms. In such matters Nature does not seem to discriminate between one side of the garden hedge and the other. The Martagon Lily is a very old species with a wide distribution from Spain, through Europe into Asia, and in all that area albino forms should not be rare. Records of them, however, are undoubtedly rare, and such as are available are of recent date.

In 1890, M. Henri Correvon found three albino plants growing in the alpine herbage near Bourg Saint Pierre,* and in the summer of the present year Mr. H. Cowley found them growing abundantly in a wood above Madrano in the Val Ticino, near Mont St. Gothard.† When Visiani found the dusky form of L. Martagon he called Cattaniae,‡ on the Dalmatian coast, he made no mention of a wild white-flowered variety as, assuredly, he would have, if he had seen one. Max Leichtlin, who collected the variety dalmaticum § of L. Martagon in the neighbourhood of Krivoscie on the frontier of Montenegro and Albania, and introduced it to cultivation in 1875, told me that he saw no white form of it; but in 1903 he sent me some bulbs of an albino form which had come spontaneously among some seedlings of L. M. var. dalmaticum in his garden at Baden-Baden. Except for the colour, this white form of L. M. var. dalmaticum, of which I have distributed many bulbs to friends, is a replica of the typical variety and stands apart from what may be called the ordinary form of L. Martagon var. album. The colour is not white, but ivory; the flowers are large and the petals more waxy than in the latter; the anthers are golden and the nectariferous furrow a brilliant larch-green. The habit and stature of this Lily are comparable to that of dalmaticum. Under seminal propagation about a third of the seedlings come true. This white form of L. Martagon var. dalmaticum has been distributed as L. Martagon var. album superbum, no doubt, to distinguish it from the ordinary form, but I can find no official publication of the name, and it was probably first used in a nurseryman's catalogue.

In illustration of the spontaneous origin of this fine albino, Messrs. Stormonth, of Kirkbride, report‖ that some years ago seeds of the so-called L. Martagon var. album superbum gave good forms of the variety dalmaticum and included one or two with white markings in the centre of the petals. Seeds of the latter varieties threw several fine, all-white forms.

The poverty of recorded examples of the wild albino form of L. Martagon var. album may reasonably be explained by the fact that it has not naturally so robust a constitution as the type, and propagates itself vegetatively. On the other hand, early records of the Lily in gardens are equally rare and the inevitable result of his researches is to leave the student in doubt as to the early history of the plant. The point is one solely of historical interest, for, as indicated above, the albino form is undoubtedly of spontaneous origin.

The garden history of the Lily is not rich in detail. There is no mention of it in the list of cultivated plants Gerard published in 1596,¶ and it was apparently unknown to Linnaeus. In his *Paradisus* (1629) Parkinson called the variety, Martagon Flore Albo and wrote of it: "We have also some other of this kind, the first whereof hath his stalke and leafe greener than the former, the stalke is a little higher, but not bearing so thicke a head of flowers, although much more plentifull than the lesser Mountaine Lilly, being altogether of a fine white colour, without any spots, or but very few, and that but sometimes also; the pendents in the middle of this flower are not red, as the former, but yellow; the roote of this, and of the other two that follow,* are of a pale yellow colour, the cloves or scales of them being brittle, but not closely compact, yet so as if two, and sometimes three scales or cloves grew one upon the head or upperpart of another; which difference is a speciall note to know these three kindes, from any other kinde of Mountaine Lilly, as in all old rootes that I have seene, I have observed, as also in them that are reasonably well growne, but in the young rootes it is not yet so manifest."

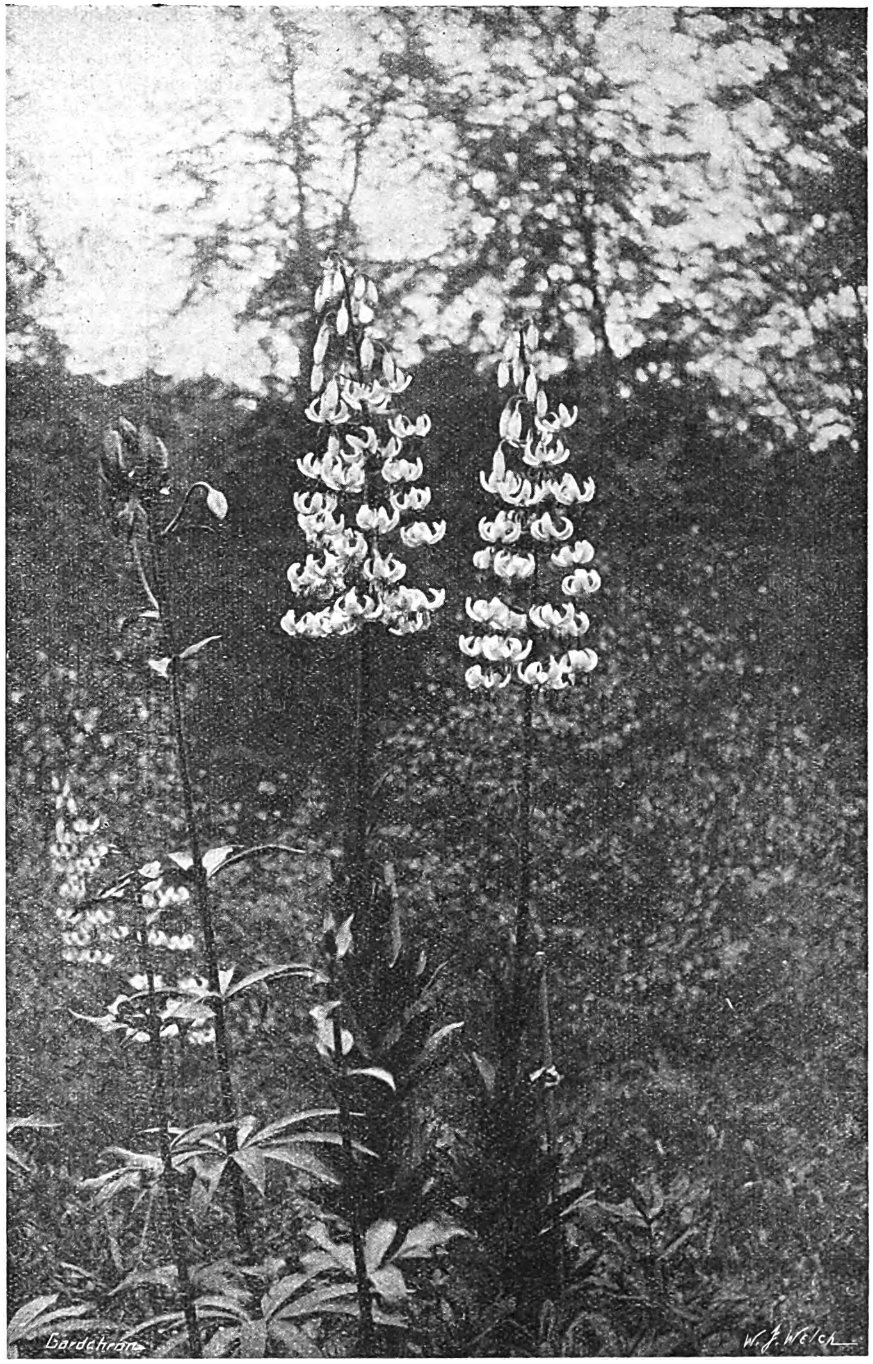

FIG. 118.—LILIUM MARTAGON VAR. ALBUM IN SIR J. B. FARMER'S GARDEN AT GERRARD'S CROSS, 1913.

Parkinson also wrote of a form of the white Martagon Lily in which "the flowers are not altogether so white, and besides hath many reddish spots on the inside of the leaves of the flowers," as he called the petals, "and the stalke also is not so greene but brownish."

It seems clear that in a general way the cultivated forms of the white Martagon Lily have not altered much since Parkinson's day, and in the absence of formal publication we have to rely on what he tells us about them. They have been taken in hand, however, by Dutch nurserymen, and an attempt made to segregate them into groups in which the white basic colour of the petals is freckled or marked or suffused more or less heavily with the purple of the type. In some of these colour varieties the tips of the petals only show a trace of purple; in others the colour is only noticeable on the reverse of the petals, and none of them is to be confused with those seedling forms of L. Martagon in which the petal colour is that of a faint blush. Names have been given to the albino forms, such as purpureo maculato, but except as curiosities, they are hardly worth growing. The flowers are usually small, often no larger than a florin, the stature is usually poor, and it cannot be sufficiently understood that none of them is L. Martagon var. album, for which they are so often sold. Except for the green furrow the latter has no trace of colour about its petals, which are paper-white.

Although the percentage of true germination varies within wide limits, these colour forms may make their appearance in every batch of seedlings raised from L. Martagon var. album, but there are some forms of the latter which throw a greater proportion of white-flowered seedlings than other forms do. Anyone wishing to raise the white form from seeds should choose only the seeds from the finest plants in which the petals are innocent of any suspicion of colour; but the surest way is to propagate vegetatively, that is, by scales, stem cuttings or stem bulblets. If the stem of L. Martagon var. album is wrenched from the bulb by a quick, twisting pull and "heeled" into the ground, a number of small bulbs will form on that part of the stem which is below ground. The process is assisted if the stem is notched with a pen-knife, for in every notch a small bulb will form. The time for the operation is just when the flowers are fading, and it is perhaps needless to point out thatfthe ground about the buried stem should not be allowed to dry.

* Refers to the white, spotted Martagon and the blush Martagon.

Happily, propagation is assisted by the numerous little bulbs which naturally form in the scales of the mother bulbs of the Martagon Lily. This is specially the case in poor ground, and often a mother bulb will be found to have broken up into a mass of small, independent bulbs, each with roots. When this happens, the bulb should be lifted, washed in a kitchen sieve, and each little bulb planted in a nursery bed. From a three-inch bulb I once took 123 small bulbs, varying in size from a Filbert to a Pea, as well as a handful of scales, to each of which was attached a bulblet of minute size. The latter should be panned for a time.

Like so many other Lilies, L. Martagon var. album has a disturbing habit of flowering bravely for four or five years, growing taller and more flowery in good seasons as the years pass. Then, just, perhaps, as the grower has cozened himself into thinking that he has mastered the cultivation of the plant, it will fail him and content itself by throwing up a few puny stems. The fact seems to be that when in comfortable surroundings the Lily prospers until it reaches its optimum, and then falls away. It cannot be stated that all the members of the genus behave in this way, because many of them travel about underground, continually finding fresh places for themselves; but those with bulbs of the type of L. Martagon often break up in the manner indicated. The cultivator's remedy is to recognise the peculiarities of the plant and when the time comes, lift the mother bulbs, treat them as already described and renew the clumps from his reserve beds. The peculiarity indicated above seems to apply more consistently to the white Martagon Lily than to the type and probably accounts for the scarcity of old examples or old clumps of it.

L. Martagon var. album is in no sense calcifugal, and I have grown specimens in ground in which there was enough chalk almost to blanch the leaves. But lime is not essential to this Lily, which is at its best in a "holding," sandy loam. It will grow in dry places and in the eye of the sun, but is happier in broken shade with moisture within reach of the roots. Slugs are peculiarly partial to the bulbs, which are of so acrid a nature that mice rarely touch them. L. Martagon and its varieties often have primitive aerial roots at the base of the stem. *A. Grove.*

PLANTS NEW OR NOTEWORTHY.

TWO NEW GARDEN ANNUALS.

The following two new species of Dorotheanthus are pretty garden annuals, of which good dried material and seeds were sent to me last year by Dr. J. Muir. In general appearance they both resemble D. bellidiformis, N. E. Br., better known as Mesembryanthemum criniflorum, but differing in their flowers and characters mentioned below. Both are glabrous and covered with glittering, watery papulae, especially upon the underside of the leaves.

Dorotheanthus oculatus, N. E. Br.—Leaves ½-2 inches long, 1½-7 inches broad, narrowly spathulate-lanceolate to somewhat cuneately linear, acute. Pedicels 1½–2 inches long. Calyx with its longer lobes 3-4 lines long, becoming 6–9 lines long in fruit. Corolla 1¼-1½ inch in diameter; petals notched or toothed at the apex, varying in colour, but always with a dark purple spot at the base. Stamens with the filaments and anthers entirely of a rich, dark purple. Stigmas 5-7, erect, ½-1 line long, dark purple, becoming 2-4 lines long in fruit and less spreading than in D. bellidiformis. Capsule 5-6 (rarely up to 8) lines in diameter.—D. criniflorus, L. Bol. in *S. Afr. Gard.*, 1928, p. 126, and *Notes on Mes.* I, p. 54 and 56 (with Fig.). Stigmatocarpum criniflorum, L. Bol. in *S. Afr. Gard.*, 1927, p. 326, and *Notes on Mes.* I, p. 82; not Mesembryanthemum criniflorum, Linne.

Malmesbury Division: Vicinity of Buck Bay; cultivated specimens, Muir 4,290!

Dorotheanthus Muirii, N. E. Br.—Leaves ½-2 inches long, ¾-2½ lines broad, linear to spathulately linear-lanceolate, acute or obtuse. Pedicels ¾-2 inches long. Calyx with the longer lobes about 3 lines long, becoming 4-8 lines long in fruit, linear or slightly dilated upwards from a deltoid base, obtuse. Corolla 1-1½ inch in diameter; petals obtuse or notched at the apex, rose-pink, without a darker spot at the base. Filaments of the stamens whitish or slightly tinted with rose; anthers pale yellow. Stigmas 5, recurved-spreading, about 1 line long, whitish, rosy at the basal part, becoming 2½-3 lines long in fruit. Capsule 4-5 lines in diameter.

Riversdale Division: Growing only in the sandy coast-belt, at Rietvlei, Muir 967; near Albertinia, Muir 4,291; Melkhoutfontein, Muir 4,292; and Droogevlakte, 400 feet altitude, Muir 4,293. *N. E. Brown.*

NOTES FROM WISLEY.

It is in such seasons as the present that the value of good cultivation is made evident, and in no garden is this shown to better advantage than at Wisley where, although no rain has fallen for many weeks, the numerous visitors are greeted with several magnificent displays of flowers.

The value of the annual Aster as a dry-season plant is well demonstrated by the trial of numerous types and varieties of this subject now in progress in the recently laid-out flower trial grounds. Here some twenty-one thousand plants form an unbroken drift of wonderful colouring, in every shade of white, cream, pink to deep red, and lilac to deep purple, and a visit to Wisley to see these alone would be well worth while. The Asters are planted in their various sections, ranging from the small, button-flowered Lilliput type—quaintly attractive and compact in growth—to the Californian and Victoria Giant, and magnificent Ostrich Plume sorts. The single-flowered sorts are also very fine and in most instances very free, while the Anemone-flowered varieties will also appeal to many.

Another interesting trial is that of annual Gaillardias, a fine bed of these being now in full bloom; the flowers are in shades of cream, orange and red, and of varying size and form.

A trial which should be of interest—it was instituted this year and is to become permanent—is that of early-flowering Chrysanthemums, of which three-hundred-and-fifty-two varieties have already been received this year. As they were planted late and the weather has been very much against them, these will be judged for the first time next year, when they should make an extremely attractive display.

Wisley in autumn might well be termed the Mecca of Dahlia enthusiasts, for all who are interested in this popular flower make a point of visiting the Dahlia trial at least once during the season. The Dahlias are grown under ordinary garden conditions, no disbudding or other operations designed for the production of specimen blooms being practised, so that the visitor is able to appraise each variety at its garden value. The colour picture produced by these Dahlias can only be described as unique, and as all the varieties are of first-class merit, the difficulty lies in selecting the best.

They are planted in their various sections, the Paeony-flowered, both small and large, taking the lead in floriferousness, closely followed by the Decorative sorts. The vast improvement that has taken place within recent years in Cactus Dahlias is shown to the full in this trial, for whereas the Cactus Dahlia of bygone days hid its flowers very effectively among its foliage, the modern varieties, as exemplified at Wisley, hold their lovely blooms well above the leaves. Another feature of the Dahlia trial this year is the inclusion of a series of varieties—large-flowered Decorative sorts—from British Columbia, but although these are of interest in demonstrating the type of Dahlia popular in their land of origin, none of them can be regarded as an improvement upon the varieties now in general cultivation in this country.

In several parts of the gardens the effect of the shortage of rain is evident, the lawns in exposed positions being particularly dry and parched, but it is surprising how fresh and verdant the gardens are generally.

In Seven Acres, for instance, which but a few years ago was a grassland waste, the trees and shrubs in the broad borders have made surprising growth, and a number of them are fruiting well, although fruits are not so evident as in former years; however, the large bed of hybrid Barberries on the pond side should prove a source of great attraction in the course of a week or two. The pond itself is bright with many Water Lilies of vigorous habit, while at one end a bright splash of colour is provided by the bright blue spikes of a mass of Pontederia cordata.

One of the chief features in this section is the Heath garden, which has been a success since its inception. Although at the present time few Heaths are in flower, exceptions are found in the Daboecias, which form lovely undulating drifts of colour, while the several varieties of Erica vagans, although now past their best, still carry sufficient blooms to add to the generally pleasing effect.

In the several ponds, dotted about the gardens, the Water Lilies continue to produce their lovely blooms, while on the margin of one of the ponds is a very effective bed of the rich orange-yellow flowered Senecio Clivorum, an ideal waterside plant.

Numerous Michaelmas Daisies contribute greatly to the pleasing effect obtaining in the herbaceous borders; incidentally, the various forms of Aster Amellus are worth inspecting in the trial quarters, where large clumps of many grand varieties are now in full bloom.

The herbaceous borders have been skilfully designed, so that even at this season there is no preponderence of one colour; which is as it should be. Although the perennial Asters are greatly in evidence, the varieties present a considerable range of colour shades. Yellow, a colour which is apt to dominate the border in autumn, is provided sparingly by various Heleniums, Rudbeckias and Helianthuses so placed as to lighten the borders but not to dominate them, while other subjects which add their quota to the general colourful display are various Salvias, including the dainty Salvia farinosa, in one clump of which there is a pure white sport, and S. Horminum, with its rich purple bracts; several silvery-foliaged Artemisias; the tall-growing Gypsophila Rokejeka, with its giant sprays of small, pink-tinted flowers; Monarda fistulosa, still flowering freely; the various forms of Sedum spectabile and several Coreopses, including the dainty C. verticillata.

At the laboratory end of the shrub border which borders the drive leading to the propagating department, a grand specimen of the rather tender Clerodendron trichotomum is in full flower, while against the wall of the laboratory Clerodendron foetidum is flowering freely next to a young specimen of the attractive Azara microphylla var. variegata, while close to it Caryopteris glutinosa is also laden with blooms.

So it will be seen that, although the season is fast drawing to its close, flowers are by no means lacking at Wisley, in fact, in some quarters they are very much in evidence, while even in the wild garden and on the rock garden there is still much of interest to be seen, and the Roses in the borders flanking the main walk have bedecked themselves in a bright array of blooms preparatory to seeking their winter repose.

Lastly, the visitor may be recommended to visit the exhibition fruit room, another recently acquired attraction, to inspect the specimen fruits of numerous Apples and Pears, all instructively labelled with their season of use and purpose. *F.*

NOTES FROM A WELSH GARDEN.

Kirengeshoma palmata is now (early September) at its best, but it will continue to yield its abundant blossoms until November frosts come along, having been flowering for nearly three months. This singularly ornamental plant is an admirable subject for a half-shaded corner where the soil is well-drained, cool and deep. My old clump is now nearly six feet across, and fully a yard in height. Some of the vine-like leaves are nine inches in diameter, and over and around the great mass are displayed the elegantly drooping flower flights, their glossy, wine-red stalks tipped with the ivory-yellow of bud and blossom. Along with this Japanese curiosity is a lusty colony of Gentian asclepiadea whose violet and blue flowers have in those of their companion a harmonious association. Some of the Clethras are occupying this cool corner, C. canescens excelling C. alnifolia in the size and shapeliness of its creamy trusses, while both of them yield a fresh Hawthorn fragrance.

Crowning a little elevation at the margin of a small pool is the silver-leaved Salix lanata var. Stuartii. Polygonum vaccinifolium carpets the ground about the Willow and drops its curtain of rose-pink flowers over the edge into the water on whose immediate surface are floating the prettily-dappled, bronzy leaves and delightful little primrose-yellow flowers of that tiny Nymphaea, N. pygmaea var. helvola. At the opposite side of the pool are the decorative leafage and bright blue spikes of Pontederia cordata, the "Jamaican Water Plantain," which happens to come from North America, and among some bigger things is the stately foliage and flower panicles of Cyperus longus. If this plant cannot equal the grace of some of its more aristocratic relations, it has a rare elegance combined with an ability to resist wind, and it does not offend very seriously by escaping from its restricted corner.

That excellent little shrub, Phyllothamnus erectus has, as it often does, produced a late crop of its delightful rose-pink flowers. Gaultheria procumbens, the last of a small collection to flower, is carrying a cheerful array of pink and white bells, most of the remainder of the genus being in fruit. The exceedingly dry season, however, has done much to mar the harvesting prospects of these little shrubs. G. cuneata has some nice clusters of its snow-white berries; G. antipoda a few bunches of crimson ones, and G. perplexa is hiding beneath its spindly twigs and narrow leaves a promising show of rosy-white. G. tricophylla, perhaps the most delightful of all, also gives us a small late yield of its fat, china-blue berries, but the drought has brought about a complete failure of all the taller kinds. Perhaps the finest berry-bearing shrub in the garden during late August and early September is Cotoneaster bullata. This splendid shrub, or small tree, never fails to crop heavily. Its berries, in large drooping clusters, are a rich glossy crimson and nearly half-an-inch across, the habit of the species is singularly pleasing, and the handsome leaves colour well in autumn. Unfortunately the blackbirds are too fond of these fruits, whereas those of Euonymus planipes, close by, are untouched. This Japanese Spindle rivals the above Cotoneaster as an early-fruiting shrub of great merit, its blood-red, five-lobed "lanterns" with their orange seeds swinging at the ends of slender stalks in quantities from every branch. The leaves of E. planipes turn a fine yellow just before they fall, at which stage fruits and foliage together create a most brilliant glow of colour.

The hot, dry season has suited the Ceratostigmas, even the tardy C. Griffithii flowering freely before its usual date here. As a flowering shrub, that species is not, in my opinion, so pleasing as C. Willmottianum, but its foliage is certainly attractive. As for the old C. plumbaginoides, Lady Larpent's Leadwort, this easily holds its own against the above two. Its extreme hardiness is, of course, in its favour, it will flourish in the most arid of sun-beaten soils or dry wall, its deep blue flowers are larger than those of the others, and the autumn leaf colour which it develops will not be past unnoticed in the late autumn rock garden.

Pentstemon Eatonii, with tubular flowers of a brilliant scarlet, promises to be as useful a plant here as it has proved elsewhere, but I have been even better pleased with P. utahensis. The large and ample blossoms of the latter species are a most delicate shade of palest lavender, luminous with opal lights. So refined in hue are these exquisite blossoms that they make those of P. heterophyllus look positively gross, and even the charming bugles of P. Scouleri at their best are anything but improved by the comparison.

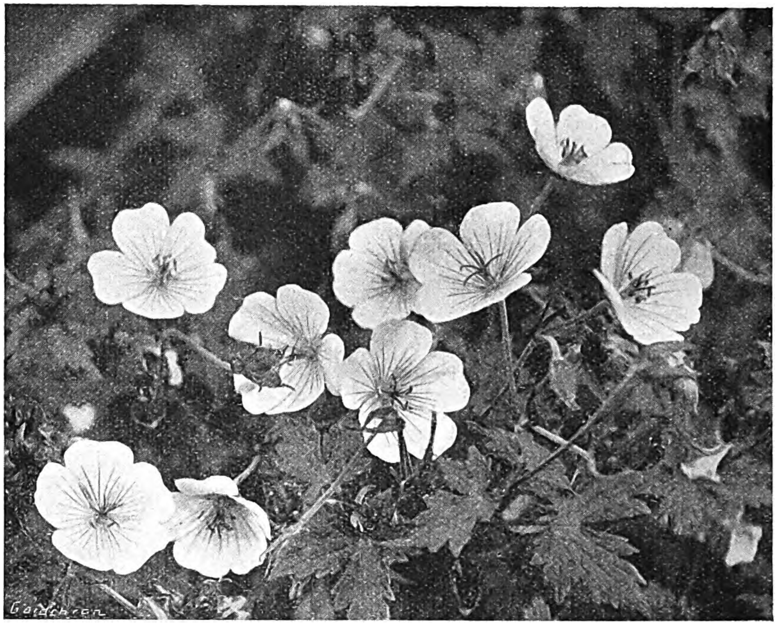

FIG. 119.—GERANIUM WALLICHIANUM VAR. E. C. BUXTON.

A colony of Allium Beesianum is flowering freely in the thin shade of some American Rose species, the Harebell-blue of their drooping clusters being more pleasing in a subdued light. Hard-by these, and also in part shade, is a group of Geranium Wallichianum var. E. C. Buxton (Fig. 119). This is undoubtedly the best of all the later Geraniums, and one that would not be eclipsed by many of any other season. I find this admirable plant comes very fairly true from seeds, but there is no doubt that the colour varies a little with the season, a plant that shows a distinct shade of the ancestral red one year being quite a good blue the next. This, of course, applies to many flowers, but it has to be reckoned with by those who expect the best of Buxton's Geranium, and the fact that this is a shade plant and a lover of cool, rocky soil must also be realised if one is to get the full beauty of the white-zoned, Nemophila-blue flowers.

Calceolaria chelidonifolium is a cheerful and pretty little plant, one of those useful things which take care of themselves and crop up in unexpected places. Sir Herbert Maxwell, who kindly gave me seeds of this species, will, I am sure, be interested to learn that seedlings of this Calceolaria not only survived last winter here, but that the plant is as firmly naturalised as it is in his own beautiful garden. Linum campanulatum of the lists, which is so close to L. flavum as to be almost indistinguishable, is always a trustworthy late-bloomer on a dry rock garden ledge, and here many of the Erodiums will give a hearty yield of blossom until November. The clear rich blue rays of Felicia rotundifolia, so effectively centred by the yellow disk, will not pass unobserved among these sun-worshippers. This is, of course, not a hardy plant, but one of such quality and charm that it is always worth while wintering a pot of cuttings in a cold frame. No less can be written of the more uncommon F. abyssinica, which has finely-cut foliage and flowers of a cool rosy-lavender. Aster Thompsonii and A. T. var. nana, the one in the border and the other among the rock plants, are both admirable subjects full of quality and goodwill, and the long, narrow rays of their delightful blossoms are a most appealing shade of lavender-blue.

Kniphofia Macowanii is an August-September bloomer of such reliability and high merit that one is surprised it has not made more headway into popularity during the fifty odd years it has been with us. It has, I believe, been freely used in hybridising, but the true plant with its very moderate tufts of dark green leaves, sturdy stems two feet long and large, cone-shaped inflorescences, glowing with scarlet and orange, are exceedingly useful in the mixed border, the rock garden or open woodland. Moreover, I have found this Kniphofia much hardier than many of its kind. Another good old border plant which seems to be getting overlooked, is Tritonia rosea. The fresh, shrimpy rose-pink of the flowers which it yields so abundantly from midsummer to November is an uncommon and attractive colour, and as pleasing indoors as it is in the border. The plant never offends by spreading unduly, it is perfectly hardy in a really dry, gritty soil, and is very useful for associating with other subjects of delicate colouring, such as the Cypellas and some of the Moraeas. The flowers of the above Tritonia are much the same colour as those of Acantholimon venustum, for which also no spot is too hot and dry. This plant is, of course, long past flowering, but the chaffy cups which encased the flowers and which are still retained are decidedly ornamental. The glaucous, spiny mound of the plant bristles with the gracefully-curved spent flowering stems, each of which from base to tip, carries an array of these delicately-cut, little, papery wine-glasses in a warm tan-brown. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXI.—UP THE RIDGE.

OUR chief reconnaissances were undertaken on August 18, 19, 21, 28, and September 2. On August 18, the day after we arrived at our new camp, I went up the ridge alone, to seek the path, but did not get very far. Next day, Buttercup and I went out, taking Hubble with us. Before long we reached the beginning of the Abies forest, where I was delighted to find the yellow Bryocarpum quite common. We soon reached the end of the path, and set Hubble to cut a way through the dense growth of 'Falconeri' Rhododendron, now a beautiful sight; for the bushes had opened out their silvery-white leaves which shot up in fountains among the warm red-brown and bottle-green of the old foliage. I noticed also the cherry-red Enkianthus, and a stiff-leafed Ilex of which I wanted seeds. Viburnum Wardii was plentiful, and so were several of the Kaso Rhododendrons, including the big tree 'Lacteum,' and R. Keysii. While we were hacking our way through solid forest, and climbing steeply, the rain came down in sheets. We reached the summit we were aiming at, but, of course, could see nothing; and having done enough for one day, we returned to camp, only to find that it had not rained there at all! (This was at the beginning of the drought, when we were shouting for water).

On August 21, we tried again, and after cutting the path a little further, picked up another trail, which we lost about a mile on. Meanwhile, the ridge had descended, and climbed again. We were slowly feeling our way towards the distant peak, and meanwhile I found some more of the Rhododendrons; but towards the end we lost the ridge, and could not discover in which direction to cast.

During the following week I explored some of the gullies we had found, looking for Primulas, and, on the 23rd, in a north gulley, I had the good fortune to find the new 'Geranioides' Primula, and also the sunny-yellow 'Candelabra.' "Now," thought I to myself, "we'll soon have the red Sikkimensis." But I was wrong. Another nice plant in these north gullies was a Nummularia with ascending stems and nodding flowers leaning out of the leaf-axils on longish stalks. It was bright and perky, buttering the rocks with a placid yellow colour. There was also a Buddleia, almost herbaceous, its weak stems leaning floppily down the steep face, as though too tired to hold up the large leaves and clotted, orange-eyed flowers. Even if it grew upright it would never attain five feet, but the flowers are deliciously scented. While I was scouting around these gullies, and Hubble was below looking for food, Buttercup took on the tedious job of fagging water from the spring I had discovered; a full petrol can a day was our ration.

On August 28 we made a third assault on the alpine region, and actually reached the main divide and an alpine top, beyond which the provoking ridge dipped down once more into Rhododendron-Abies forest. However, I found the pink 'Barbatum,' the big-leafed 'Barbatum' and R. tephropeplum. I also noticed in fruit a small alpine Gaultheria which I had not seen on Kaso; it had ascending or erect stems, covered with mossy leaves, from among which peeped bright rose-pink 'berries.'

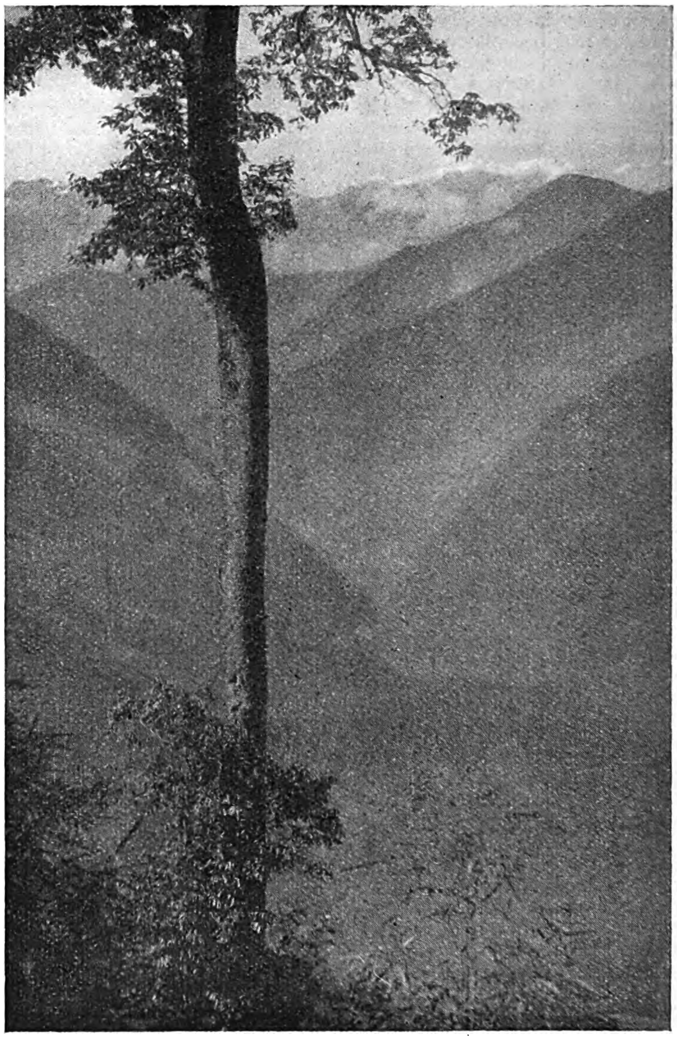

FIG. 120.—THE DELEI VALLEY.

The only new Rhododendron I found was a form of R. virgatum in fruit; but in some of the higher gullies there were autumn plants in flower, which had overflowed from the teeming Alps; mostly tall herbs, such as Rodgersia, Astilbe, a yellow Salvia, a Geranium with lurid crimson flowers, the purple or magenta Caltha, several species of Impatiens, and more of Polygonum, one with fluffy clouds of snow-white flowers, and a Phlomis. But the plant I was in search of, the one I most wanted to find, was the lovely red 'Sikkimensis' Primula—the world would be well lost for it, and the possibility of not finding it cost me many a sleepless night. I descended several good-looking gullies, starting at ever higher levels as we worked our way along the ridge, but all to no purpose; the only other Primulas I found were P. prenantha and P. vernicosa, both of them rather poor stuff.

It will be seen from what has been written above that circumstances compelled us to do over again in August and September the work already done in June and July. It seemed a sinful waste of time. Of course, we found a few new plants, particularly autumn-flowering species; but we were engaged principally in re-discovering old ones. Had our new camp been higher up the valley, instead of lower down, we might have found all the Kaso plants quickly, and a whole new crop of alpines as well. Explorers have told me that it takes three years to achieve results in a virgin field. The first year is spent in reconnaissance—ways and means, routes, camping grounds, resources, transport conditions, work to be done, and so forth. In the second year, the real work is done, or as much of it as possible. The third year is devoted to 'mopping up'—but this might easily be dispensed with; two years, however, are essential to success. I am afraid that the Delei Valley will have to be left to my successors; the jungle is not 'calling' for me as the desert is said to 'call' for popular explorers—by themselves. In fact, I should not feel that I had missed anything in life if I never saw the Delei Valley again.

On September 2 we made another effort to reach Polon, and followed the ridge some distance beyond the first alpine top, going steadily down, down into the forest again through dense thickets of Bamboo and 'Falconeri' Rhododendrons, with scattered Abies and 'Barbatum' Rhododendrons. Worse still, after descending several hundred feet, the path once again came to an end (or appeared to do so) although why there should be a path along the ridge, unless it continued to Polon, was a mystery. We knew that the peak was quite close, but we could see nothing on account of the dense clouds which were rolling up from the deep valleys on either side. I find in my diary for that day the following significant remark: "Thus we have carried the reconnaissance a step further, but shall never find the route to Polon until we have a really fine day and can see what we are doing." After I had written that, it rained for six weeks!

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; Sept. 7, 14, 1929.

Thus, from the day we arrived in Camp VI, we set to work to find the best plants discovered on Kaso, and this proved a double labour, since they were no longer in flower. It was certain, however, that we would not find all of them, and the only way to get seeds of the rarest species, and of those which were not merely rare, but unique,[*] was to return to Kaso. It might, we thought, be possible to reach Kaso by following the main divide along the crest of the ridge; when the clouds rolled by Kaso was mainly visible about fifteen miles distant, but part of the ridge was hidden by an intervening peak called Polon. Our first object in life, therefore, was to climb Polon, and see how the land lay on the other side.

Every week I went over the lists of seed plants and wrote off those which had been found on Polon ridge, and noticed with satisfaction that the tale of those which remained to be found dwindled steadily. I had all the Kaso plants marked, and if we did not find them on Polon, and could not get at them over the top of Polon, then I would have to return to Kaso by the valley—a thing to be avoided at all costs. By the end of August I had written off half my liabilities; but the debts which could be considered good did not include the best things. A trip to Kaso was inevitable. Meanwhile, among other plants which had been found, were the small, pink Rose, the polygon-leafed Podophyllum, Rhododendron Lindleyi, the purple 'Brachyanthum' Rhododendron and the silver-leafed 'Boothii.'

Magnolia rostrata was fairly common.—I saw one magnificent specimen in fruit which must have borne fifty or sixty flowers, and the whole perfectly situated on an open slope below the ridge, so that one looked plumb on to it; unfortunately, we did not happen to be here in May. M. globosa, on the other hand, which was so common on Kaso, was absent from Polon, its place being taken by the species described in the last chapter. M. mollicomata, the eastern form of M. Campbellii, I did not see at all; and the only other Magnolia seen here was a sub-tropical species with very small cones. It grows at 4,000 to 5,000 feet, but I did not see it in flower.

The nearer the mountains approach the plains the more the pressure of the Indo-Malayan flora is felt, so that at the same altitude, the mountain flora is very different at the lower end of the Delei Valley, say, and at its head; for the head of the valley is in contact with the Tibetan flora, which likewise makes its influence felt.

In other words, the composition of the mountain flora is influenced by the adjacent floral region, although it maintains its character as temperate rain forest, Conifer forest, alpine, meadow, and so on. Then again, valley and mountain, at the same altitude have many unlike species; so that the flora changes rapidly as one climbs these frontier ranges. Kaso Ridge and Polon Ridge were about ten miles apart, and quite a number of species were absent from the one which were found on the other. Kaso Ridge, of course, being connected with the higher peak, was much richer in alpine species, but as we were not on Polon when these plants—the dwarf Iris, spotted Nomocharis, Cypripediums, and most of the Primulas, for instance—were in flower, it is, perhaps, unwise to state that they do not grow there, although we did not see them. *F. Kingdon Ward.*

---

[*] I use the word *unique* advisedly to distinguish those plants of which a solitary specimen, or half-a-dozen specimens in one spot, were discovered; believing them to be the only specimens in existence. Thus the two new 'Barbatum' Rhododendrons, K.W. 8255 and K.W. 8431, are *unique*.

PROBLEMS OF PLANT LIFE.[*]

IX.—Breathing Pores or Stomata.

(*Continued from p. 208.*)

It is difficult, in the present state of our knowledge, to realise what ideas the old-time students of plant physiology had before the discovery of stomata. This discovery opened up a new world, and made the analogy between plant and animal appear much closer than it could have done before. To think that plants had mouths, and breathed or transpired by their means! In some respects they suggested the gills of fishes, in others the spiracles of insects, and in yet other respects they seemed to be analogous to the mouths of animals and man.

It had already been observed that plants "wept," although their eyes had not been discovered, and other actions characteristic of animals had been noted, but the process of taking in air by the leaves was unimaginable. So late as the days of Malpighi (1628-94), the idea prevailed that plants took up air by means of their roots from the soil, since leaves possessed no openings which could be used for such a purpose. Yet Malpighi worked for ten years on vegetable anatomy before he submitted the results of his investigations to the Royal Society. The published report shows that he had given careful attention to the structure of the bark, wood and pith, as well as to buds and leaves, flowers and fruits. He knew that cells, or utriculi entered into their structure, and that spiral vessels existed. But the stomata escaped his observation. How much of interest the discovery, if he had made it, would have added to his attempts to demonstrate the similarities between vegetable and animal organisms and their functions! True, many of his comparisons were false, as when he likened the buds of plants to the uterus and ovary of animals.

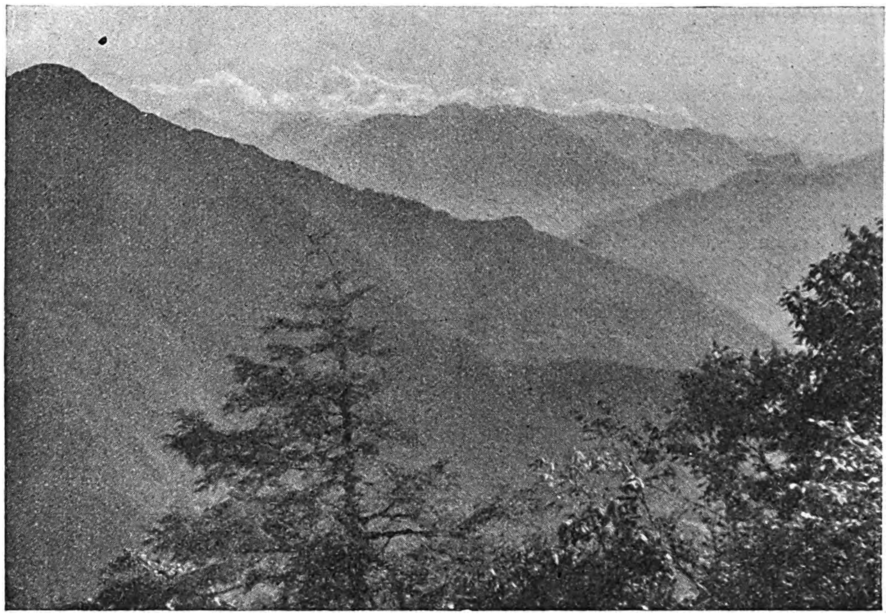

FIG. 121.—VIEW OF THE HILLS FROM LOOK-OUT AT CAMP VI.

When, at last, the stomata were discovered it took a long time to determine their exact use. This is evidenced in the first place by the names which were given to them. They were frequently described as glands, with which they seem to have been confused. Such terms as cortical glands, miliary glands (suggestive of Millet seeds), and epidermal glands, occur in the botanical literature of the eighteenth century, the latter term, in its German form of *Hautdrüsen* being used so recently as 1839 by Meyen. Yet much progress had been made meanwhile in the study of respiration and transpiration. I may mention, by way of illustration, the work of Professor Théodore de Saussure (1767-1845), who combined with his knowledge of geology and botany a practical familiarity with chemistry. Adopting the quantitative method of chemical research which had been established by Lavoisier (1743-94) he was able to experiment in a way unknown to earlier investigators. By enclosing plants in vessels which contained a known quantity of air, and observing their growth under different conditions, he was able to test the changes in the composition of the air thus brought about. In this way he "established the quantitative relation between the amount of carbon dioxide absorbed by the plant in light, and the quantity of oxygen simultaneously given off by it. In the same way he found out the quantity of oxygen absorbed by a plant at night, and also the quantity of water consumed in association with the absorption of carbonic acid that is required for the growth of the plant." Yet it was de Saussure who called stomata cortical glands rather than breathing pores, and de Candolle who called them cortical pores. Indeed, it was not until 1819 that the term stoma (Greek *Στόμα*, a mouth), plural stomata, was introduced by Link, who wrote stomatia for the plural. By German botanists they are termed *Spaltoffnungen*, or *Spaltmündungen*—the syllable *spalt* being the equivalent of the English word split. This gives us no clue to the ends which the stomata serve, and shows that when the term was introduced doubt still existed on the subject.

Stomata are natural apertures, opening outwards through the epidermis or cuticle, and are in general formed of a pair of crescentic cells which unite at their extremities. Thus they produce a more or less longitudinal slit, spalt or opening, closely resembling a mouth with its two lips. We state, however, that this is the general form, for there are exceptions. Thus, we find in certain plants three or four cells or even more. In such a case as the Ash-leaved Anemia from Brazil they undergo curious modifications, while microscopists have long been aware that in the Liverwort (Marchantia) the stomata are built up of a tier of rings, each of which is composed of four or five cells The stomata open into the tissues of the leaf or such other part of the plant upon which they are found, and are sometimes associated directly with an open space which may be regarded as an air chamber. In some instances there is a double chamber. In this way they facilitate respiration or transpiration.

---

[*] Previous studies appeared in our issues of April 13 (p. 279), June 15 (p. 446). Vol. LXXXV; July 13 (p. 30), July 20 (p. 50), July 27 (p. 71); August 17 (p. 130) September 7 (p. 188), and September 14 (p. 207).

Since they vary widely in number, position, distribution and even in function, I may enumerate a few of the points of special interest and importance. And first as to the situations where they may be looked for; since they are not absolutely confined to the leaves. We do not usually meet with stomata on the roots of plants on the one hand, or on the petals of flowers on the other. They are rare on fleshy fruits, on seeds, petioles, stems and submerged leaves, but exceptions may be found, and where they occur they are always instructive, as exceptions invariably are in nature. Thus, they may be found on the epidermis of Gourd, and on the Holly berry. They occur also on bracts, sepals, and herbaceous stems.

In examining leaves for stomata, one finds that they vary widely. In many plants they are distributed over the lower surface only, but while in some plants such as the Olive, Pear and Syringa this is the rule, in other cases they are limited to the upper surface, or occur equally on the two sides of the leaf. In general, the leaves of plants which are submerged are destitute of stomata, but in cases where the leaves of aquatic plants float on the surface of the water the rule is for the breathing pores to be on the upper side. Technical writers are constantly enlarging our vocabulary, and so it is that to-day they speak of leaves as hypostomatous (with stomata on the under surface), amphistomatous, and the like. Such details, however, are for text-books rather than for the practical gardener.

Recent investigators on the continent, during their researches into the problems connected with drought, have greatly extended our knowledge of what may be called sunken stomata with canals of considerable length leading to the air chambers. This is a point of considerable interest to plant growers in dry regions, as it throws light on the question of how plants are able to function under drought conditions. Such stomata have long been known to occur in such plants as the Oleander, Banksia, and Dryandra.

We may next take the question of numbers. How many stomata may we expect to find in a given space? The answer is that here, again, the utmost variation is to be found. Nature is fertile in her devices. Where many stomata are needed to enable the plant to function rapidly many will be found; few will occur where only few are needed. Here is what Brown stated in his *Manual of Botany*, published in 1874.

"The number of the stomata on the leaves of different plants varies greatly, from only a few up to 160,000 on a square inch; or 708,750 on an entire leaf of the Lilac, and 1,053,000 on an entire leaf of the Lime tree" (p. 55-6). He is giving a summary of the results arrived at by Lindley and other English botanists, as confirmed by Morren, Unger, Duchartre and other equally trustworthy continental biologists. We may compare this with the statement made in one of the most recent publications.*

"The number of stomata per unit area of leaf surface is [often] very great, usually between 50 and 300 per square millimetre, but in exceptional cases they may even exceed 1,000. Thus Yapp (1912) found on the lower surface of the upper leaves of the Meadow Sweet (Spiraea Ulmaria) up to nearly 1,300 per square millimetre."

At this point it may be well to give a brief summary of conclusions already reached in reference to their distribution and arrangement. Thus we find, in general, that the arrangement and form of the epidermal cells affects that of the stomata. In the case of the Conifers with needle-like leaves, for example, the stomata are arranged in rows or lines; when the cells of the epidermis are distributed equally the stomata will be orderly, and when they are scattered the stomata will be irregularly disposed. Fleshy leaves, on the whole, have fewer stomata, while among trees and shrubs the leathery leaves have the greatest number. Usually—and this is a point of great importance—plants which are normally exposed to the sun have fewer than those found in damp and shady situations. As a rule, herbaceous plants have fewer than those which are woody, and while some have stomata equally distributed on both surfaces of the leaf, some have them chiefly on the under surface, others chiefly on the upper side. The latter is normally the case with aquatic plants whose leaves float on the surface of the water. *Hilderic Friend.*

MESEMBRYANTHEMUM.

(*Continued from p.* 228.)

MITROPHYLLUM, Schwant.

4.—M. proximum, Schwant. in *Zeitschr. f. Sukkulent*, 1926, p. 182.—A shrublet 8–12 inches high (Fig. 122), with branches 2–3 lines thick, terete, slightly thickened at the nodes and with internodes ¼–1 inch long, glabrous, dark violaceous-grey. Vegetative and flowering growths intermingled on the branches, and the main or terminal cones clustered among the lateral cones at the ends of the branches and sub-sessile, or supported upon an internode 2–6 lines long. Cones 1¼–3 (rarely 4) inches long, 5–9 lines thick at the base; free leaves ¾–3 inches long, 4–7 lines broad at the base, thence tapering to an acute or sub-acute apex, concave, flat or slightly convex on the face, obtusely keeled on the back, light green, minutely papulose as in the other species. Flowers and fruit unknown.

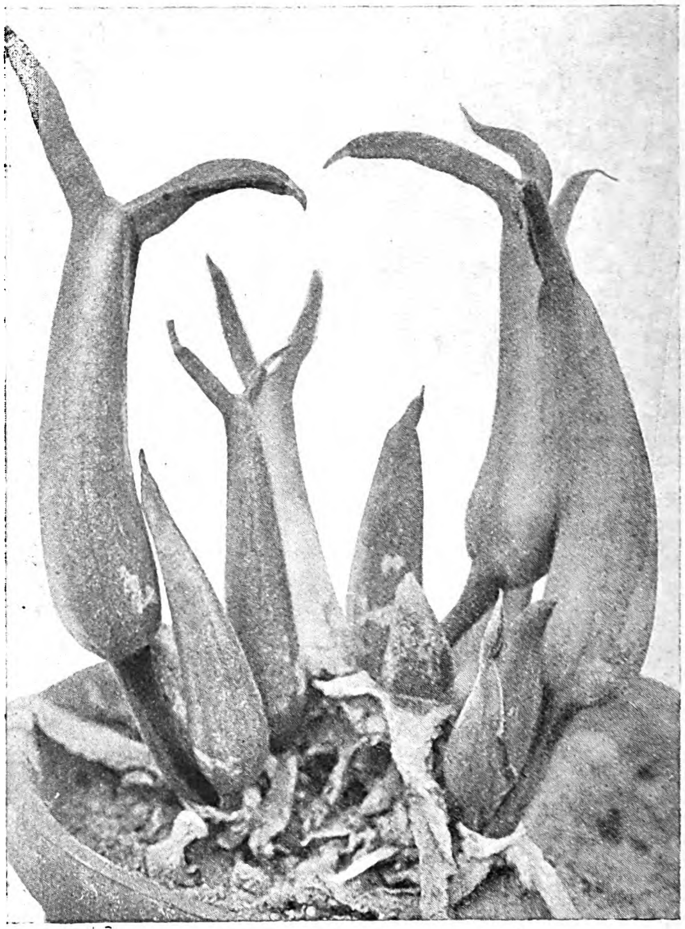

FIG. 122.—MITROPHYLLUM PROXIMUM, SCHWANT.

Cluster of growths eighteen months after rooting.

Mesembryanthemum proximum, N. E. Br. in *Journ. Linn. Soc.* Vol. XLV, p. 117, t. 5, Figs. 3 and 4; *Gard. Chron.*, 1921, Vol. LXX, p. 223, Fig. 95. Conophyllum proximum, *Schwant.* in *Zeitschr. f. Sukkulent* 1928, p. 322.

Little Namaqualand: Without precise locality; Pearson.

Fig. 117 represents a branch of the type plant when first imported. Fig. 122 represents a similar cluster of growths eighteen months after the branch bearing them had rooted, both figures of natural size, which clearly show how very different it is from M. grande, which has been mistaken for it in S. Africa.

5.—M. dissitum, Schwant. in *Zeitschr. f. Sukkulent*, 1926, p. 182 (Fig. 123).—A shrublet 12–18 inches high, with vegetative and flowering growths on the same branches, which are permanent. Branches 1½–2 lines thick, or thicker under cultivation, with internodes 1–2½ inches long, and a distinct and long internode always separating the main cones from the free pairs of leaves from which they arise, glabrous, reddish-brown, becoming dark grey with age. When at rest the vegetative cones are 1–2 inches long, 3½–5 lines thick; the free leaves are ¾–2 inches long, 4–6 lines broad at the base, thence tapering to an acute apex, flat or slightly concave above, obtusely keeled or rounded on the back; both pairs of leaves are glabrous and in their earliest stages minutely crystalline-papulose, with longer and acuter papulae along the edges at the tips, which at length disappear, green, or with reddish tips. Flowers solitary, terminal, becoming lateral in fruit. Pedicels about 6 lines long, papulose. Calyx-lobes 5–8 lines long. Corolla 1¼–1½ inch in diameter, expanding in the middle of the day; petals numerous in 3–4 series, linear, sub-acute, light yellow. Stamens about 2½–3 lines long, at first collected into a cylindric column; white, with pale yellow anthers. Stigmas 5, about 3 lines long, slenderly subulate. Ovary raised and 5-ridged on the top. Capsule when expanded about 10–11 lines in diameter, with 5 valves and cells; expanding keels flat, diverging nearly or quite from the base, with the inner edges toothed and with rather narrow marginal wings; cells somewhat acutely roofed with membranous cell-wings. L. Bol. in *Fl. Pl. of S. Afr.*, Vol. VII, t. 272.

Mesembryanthemum dissitum, N. E. Br., in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 114, t. 5, Fig. 9, and t. 6, Fig. 11. Conophyllum dissitum, Schwant. in *Zeitschr. f. Sukkulent*, 1928, p. 32.

Little Namaqualand: Among bushes on the upper slopes of hills above Daunabis; Pearson, 6,116.

This very distinct species is easily recognised by its long internodes. Fig. 123 represents a rooted cutting in its resting stage, from which it will be noted that the central cone is formed at the end of a long internode.

6.—M. cognatum, Schwant., in *Zeitschr. f. Sukkulent*, 1926, p. 182.—A much-branched shrublet about a foot high (Fig. 124). Main stem 5–7 lines thick, branches 3–4½ lines thick, with internodes ¼–1 inch long, and more or less thickened at the nodes, glabrous, brown under cultivation, pale grey when imported. United pairs of leaves forming cylindric bodies 7–15 lines long, similar to and continuous with the stem or very slightly thicker than the latter at their base, ending in a pair of widely spreading or recurving leafy tips, 1–2¼ inches long, about 2 lines broad at the base, thence gradually tapering to a sub-obtuse apex, channelled down the face, obtusely keeled down the back; the free leaves ½–1½ inch long, 3–4 lines broad at the base, thence tapering to a sub-obtuse point, flat or slightly concave on the face, keeled on the back, strongly recurved; all when young minutely papulose, with those on the margins and keel acute and tooth-like, which dry up and disappear with age; grass-green. Flowers and fruits unknown.

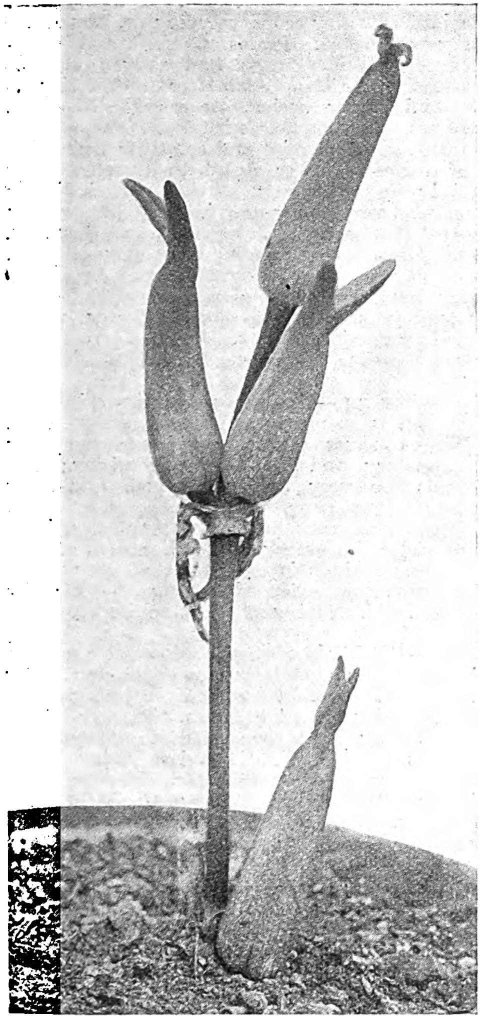

FIG. 123.—MITROPHYLLUM DISSITUM, SCHWANT.

Mesembryanthemum cognatum, N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 113, t. 7, Figs. 21–22. Conophyllum cognatum, Schwant., in *Zeitsch. f. Sukkulent*, 1928, p. 32.

Little Namaqualand: Upper slopes of hills south-west of Chubiessis; Pearson, 6,179.

The figure represents a rooted branch of the type in a state of rest.

7.—M. clivorum, Schwant., in *Zeitschr. f. Sukkulent*, 1926, p. 182.—A shrublet 10–12 inches high. Stems and branches 3–7 lines thick, with internodes 5–13 lines long, and constricted at the nodes, glabrous, at first green or reddish-brown, becoming pale grey with age. United pairs of leaves forming cylindric bodies 6–14 lines long, similar to and continuous with the stems, ending in a pair of horizontally spreading or recurving leafy tips 1–2 inches long and 2–3 lines broad at the base; the free leaves ¾–2 inches long, 3–5 lines broad and 3–4 lines thick at the base, thence tapering to a sub-obtuse point, slightly concave above, obtusely keeled beneath; all when young covered with minute, glittering, watery papulae, those on the keel and edges larger than the rest and obtuse (not pointed), of a rather dark, dull green. Flowers unknown.

Mesembryanthemum clivorum, N. E. Br. in *Journ. Linn. Soc.*, Vol. XLV., p. 113, t. 5, Figs. 5–8. Conophyllum clivorum, Schwant., in *Zeitschr. f. Sukk.*, 1928, p. 322.

Little Namaqualand: Mountain slopes between Stinkfontein Plateau and Chubiessis; Pearson, 6,200.

This species is somewhat like M. cognatum, but more lax in habit, and with a constriction at each node, that is quite wanting in M. cognatum. *N. E. Brown.*

(*To be continued.*)

THE GENUS PRIMULA.

(*Continued from p.* 231.)

RETICULATA (Wall). Reticulated P.
(Sikkimensis).

A DECIDUOUS, perennial species of loose, tufted habit with mealy resting buds. The leaves, few in number, have oblong blades two to three inches across, heart-shaped at the base, borne on slender stalks from four to six inches long; margins undulate, furnished with sharp, saw-like teeth; upper surface grey-green, usually smooth and reticulate, at times slightly hairy, underside sometimes mealy. Flower stem twelve to sixteen inches tall, very slender, usually smooth throughout, at times mealy upwards, bearing a loose umbel of nodding, slightly fragrant, yellow blossoms. Corolla about one inch long, with small, oval, erect, undulate, scarcely notched lobes; tube cylindrical below, dilated upwards, twice as long as the calyx. Introduced in 1887.

Grows in damp alpine pastures in the central and eastern Himalayas, from Nepal to Sikkim, at 12,000 to 15,000 feet above sea-level.

Culture: Good, fibrous loam and peat, in an open position, abundantly supplied with water when in growth, should suit it.

RHODANTHA (Balf. f.). Carmine-flowered P.
(Farinosae).

A pretty perennial sub-species of P. rosea (Royle) with a slender, branching root which produces numerous small rosettes of thick, smooth, shining leaves, about three inches long, with blades varying from narrowly-egg-shaped to elliptic, oblong-elliptic and egg-shaped-lance-shaped, blunt or rounded at the tip; margins somewhat cartilaginous, more or less toothed; both surfaces sprinkled with glandular pits. Flower stem about two-and-a-half inches tall, stout, usually immersed in the foliage which is well developed when the plant is in flower. The rose-coloured blossoms are borne in an erect umbel of one to eight flowers on erect, slender stalks about five-eighths-of-an-inch long. Corolla concave, about five-eighths-of-an-inch across, divided into five egg-shaped lobes cleft to the middle; tube cylindrical below, dilated upwards, about three-eighths-of-an-inch long.

Grows in damp, rocky soil in ravines in the Kurrum Valley, Afghanistan, at 9,000 to 10,000 feet above sea-level, and is apparently very local.

Culture: Plant it in peat and loam, on the edge of the bog garden, in full sun.

RHODOCHROA (W. W. Sm.). Tibetian Pixy P.
(Minutissimae).

A very dainty, dwarf perennial species hardly more than one inch tall, including the flower stem. It forms tufts or rosettes of deep green leaves, which have broadly lance-shaped or narrowly egg-shaped blades, nearly stalkless, or gradually tapering to a broad stalk, in all from a quarter- to three-eighths-of-an-inch long; margins furnished with sharp, irregular teeth; upper surface green and clothed with minute, stiff hairs, underside densely coated with white meal. Flower stem very short, hardly one-eighth-of-an-inch long, mealy, bearing one or two bright rose or deep rose blossoms immersed in the foliage. Corolla about five-eighths-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, about a quarter-of-an-inch long, with a ring in the mouth. Flowers in June and July.

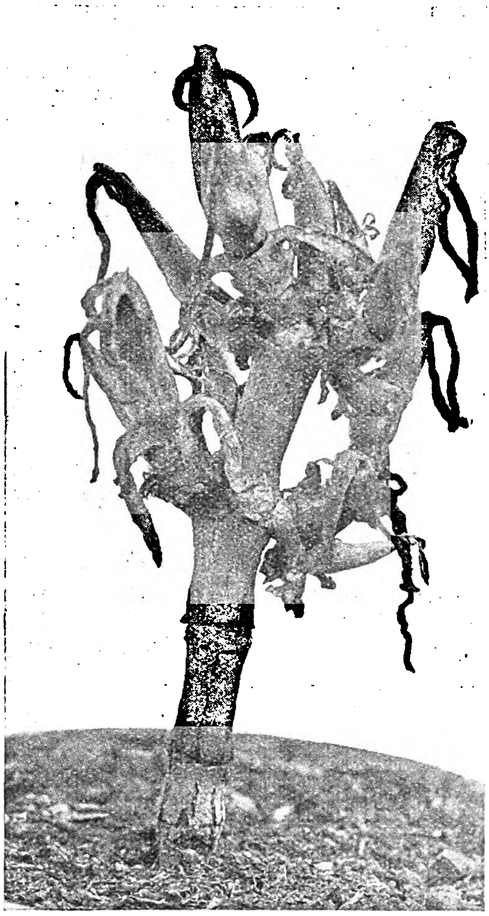

FIG. 124.—MITROPHYLLUM COGNATUM, SCHWANT.

Grows on mossy and grassy ledges of cliffs and on stony slopes among dwarf bushes, in south-eastern Tibet, at 12,000 to 15,000 feet above sea-level.

Culture: Peat and fibrous loam, in a cool, damp spot, with protection from damp in winter, are the conditions suggested.

RIGIDA (Balf. f.). Rigid P.
(Nivales).

The rootstock of this dwarf perennial species is covered with the bases of previous seasons' tufts of foliage. The slightly fleshy leaves have narrowly lance-shaped blades about three-quarters-of-an-inch long, gradually tapering to short stalks; margins slightly involute and furnished with blunt, regular teeth; upper surface more or less smooth, underside mealy. Flower stem usually solitary, bearing an umbel of two to six nodding, purplish-rose or mauve, fragrant blossoms with a white eye. Corolla flat, about half-an-inch across, with spreading, egg-shaped lobes; tube about half-an-inch long. Flowers in June and July.

Grows on open alpine ridges in short turf, near Tumbatse, in south-eastern Tibet, at 15,000 to 16,000 feet above sea-level; also on the mountains around Muli, in south-western Szechuan, at 10,000 to 12,000 feet.

Culture: Grow it in good fibrous loam and peat, in a well-drained, open spot, with protection from damp in winter.

RIPARIA (Balf. f.). River-bank P. (Malvacea).

This plant is probably a sub-species of P. neurocalyx; it produces a sparsely-leaved tuft of foliage covered with rather long, white hairs. The leaf blades vary in shape from heart-shaped or broadly oval to sub-rotund, they are from three-quarters- to one-and-a-quarter-inch long, and are borne on hairy stalks about equalling the blade in length; margins cut into numerous lobes which are furnished with sharp teeth. Flower stem about four inches tall, more or less covered with glandular hairs; the blossoms, which are lilac with a yellow tube, number about five, and are borne in an erect umbel. Corolla flat, about five-eighths-of-an-inch across, divided into five broadly heart-shaped, bifid, deeply divided lobes; tube cylindrical, slightly longer than the calyx, with a large-lobed ring in the mouth. Flowers in April and May. Not in cultivation.

Grows in damp, cool, shady places near Chago, in Kansu, at about 7,000 feet above sea-level.

Culture: Leaf-soil and loam in a cool, shady spot well-drained in winter, should suit this species, which will probably prove quite hardy in cultivation in this country.

ROSEA (Royle). Rose P. (Farinosae).

This beautiful and well-known species is a smooth, deciduous, densely-tufted perennial with bronze-coloured resting buds. The leaves, which are from four to six inches long, have egg-shaped-oblong, oval-oblong, or broadly lance-shaped blades, rounded at the tip, stalkless, or with a short, rather obscure stalk; margins furnished with sharp teeth. Flower stems stout, from six to eight inches tall, bearing an umbel of three to six rose-red blossoms. Corolla flat, three-quarters-of-an-inch to one inch across, with usually broadly heart-shaped, deeply-notched, sometimes toothed lobes; tube longer than the calyx. Flowers from May to August.

Grows in boggy alpine pastures in Afghanistan and the western Himalayas, from Kulu to Kashmir, up to 12,000 feet above sea-level. Introduced in 1879.

Culture: Plant it in peat, gritty loam and leaf-soil, and treat as a bog plant.

Var. elegans (Hook. f.) has a smaller corolla, a larger tube and narrower lobes. It is found in Afghanistan and Kashmir. In cultivation. *Bot. Mag.*, t. 6,437, in mistake for the type.

ROSIFLORA (Balf. f.). Rose-flowered P. (Farinosae).

An apparently pretty perennial plant closely allied to P. rosea, with a rosette of smooth, non-mealy leaves from three-quarters- to one-and-a-half inch long, with somewhat thick, elliptic or oblong, blunt blades half- to three-quarters-of-an-inch long, tapering to short, winged stalks; margins obscurely and remotely toothed; both surfaces dotted with numerous glands. Flower stem very short, not more than one-eighth-of-an-inch long, immersed in the foliage, and bearing an umbel of about four rose-coloured blossoms. Corolla about one inch across, very deeply divided into bifid lobes; tube narrowly cylindrical, about three-quarters-of-an-inch long, with a ten-lobed ring in the mouth. Flowers in June. Not in cultivation.

Grows in damp situations in Chitral, in north-western India, at 5,000 to 10,000 feet above sea-level.

Culture: As for P. rosea.

ROSTHORNII (Diels). Rosthon's P. (Malvacea).

This deciduous perennial is a sub-species of P. malvacea (Fr.); it produces a sparse tuft of membranous leaves with rounded, blunt blades one to three inches across, heart-shaped at the base, borne on distinct, rounded stalks two to six inches long, clothed with rather long, brownish hairs; margins sinuate and cut into small, rounded, slightly toothed lobes; both surfaces hairy, underside with long, brownish hairs on the veins. Flower stem two to ten inches tall, slender, hairy, bearing one or two superposed umbels of three to seven rose or rose-purple blossoms with a yellow eye, or mauve with a white eye, borne on stalks half-an-inch to one inch long. Corolla deeply saucer-shaped, about five-eighths-of-an-inch across, with rounded, notched lobes; tube cylindrical, longer than the calyx. Flowers in June and July.

Grows in dry soil in stony, open pastures, on ledges of limestone cliffs and occasionally in woods in Yunnan and Szechuan, at 9,000 to 11,000 feet above sea-level.

Culture: As for P. malvacea.

ROTUNDIFOLIA (Wall). Round-leaved P. (Rotundifolia).

A handsome, deciduous perennial species with stout resting buds covered with yellow meal. The tufts of membranous leaves have almost circular blades from one inch to four inches across, heart-shaped at the base, borne on stalks six to twelve inches long; margins toothed and at times almost lobed; usually more or less smooth above, coated with sulphur meal below. Flower stem six to fifteen inches tall, rather stout, covered with yellow meal and bearing several superposed umbels of purple blossoms on slender, mealy stalks half- to three-quarters-of-an-inch long. Corolla flat, half- to three-quarters-of-an-inch across, with egg-shaped, scarcely notched lobes; tube twice as long as the calyx, with a ring in the throat. Flowers in June and July. Introduced in 1833. *Bot. Mag.*, t. 3,167.

Grows in damp alpine pastures in the eastern Himalayas from Nepal to Sikkim, attaining an elevation of 13,000 feet above sea-level.

Culture: Grow it in a mixture of good fibrous loam and peat in a cool, damp spot, well drained in winter. *A. W. Darnell.*

(To be continued.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

(Continued from p. 231.)

ENGLAND, S.

KENT.—Hardy fruits have, this season, in spite of a very dry spring and summer, surpassed expectations, with the exception of Strawberries, which were a complete failure. Some varieties of Apples required thinning, while others are thinly cropped, with the result that the crop is about average. Apricots are the best crop for years. Very little summer spraying has been necessary. Plums are grown on walls here, but the crop on bush trees in this district is good. *H. Brotherston, Lympne Castle Gardens, Hythe.*

—— Apples, Pears and Cherries in this district are an average crop and good. Apples are very free from scab, even Allington Pippin and Bismarck, which are very subject to scab, could not be better than they are this year, with a good crop on standard and bush trees. We spray in spring with Cooper's winter spray. Other Apples that are cropping well are Lane's Prince Albert, Newton Wonder, and Bramley's Seedling, while most other varieties are carrying a fair crop. Pears had plenty of blossom but a lot of the fruits have dropped. The cause of this was the dry weather during May and June. Conference is holding its own, with a good crop, as a market variety; others of note that are good are Pitmaston Duchess and Doyenné du Comice. Strawberries were almost a failure owing to the severe winter and the dry May and June. Many of the plants are dead, and fruits on other plants were small. Plums are under average, the only sorts of note being Belle de Louvain and the Bush Plum; early and very late varieties are poor. Damsons are a good crop. Gooseberries, Currants and Raspberries were all very good. Peaches were good, also Figs. The soil here is a heavy loam over chalk. *J. Bone, Olantigh Gardens, Wye.*

—— All fruit trees and bushes showed splendid promise of heavy crops, carrying an abundance of good flowers. Plums, Cherries and Strawberries and bush fruits had very favourable weather conditions. At a later date, during the Apple-flowering period, we registered several degrees of frost on successive days. Strawberries showed good promise and set their fruits well, but a great number failed to develop owing chiefly to the drought at that period. Plums carried a very heavy crop in 1928, but are very scarce this season. Raspberries and Black and Red Currants bore an abundance of good friuts. Gooseberries were a small crop. Apples are very disappointing after such an abundance of good flowers. The soil here is heavy, with a good proportion of clay. *H. E. Kemp, Holmewood Gardens, Langton, Tunbridge Wells.*

MIDDLESEX.—The crops of fruits this season are somewhat patchy. Peaches are good and Cherries an average crop. Strawberries were very satisfactory, and Raspberries promising; bush Plums are very lightly cropped, and Black Currants were poor. Cooking Apples set a good crop on some trees, but dessert Apples and Pears are under the average. The lightness of crops of several kinds is due to the very severe late frosts experienced during the flowering season. *H. Markham, Wrotham Park Gardens.*

—— All kinds of fruits bloomed profusely, in most cases much later than usual, but during the flowering period the weather was generally cold and dry with night frosts. Pears and Plums are a very light crop. Certain varieties of Apples set well, the heaviest being James Grieve, which seldom fails; Lane's Prince Albert, Peasgood's Nonsuch, Beauty of Bath, Lady Sudeley, Charles Ross and an occasional tree of Cox's Orange Pippin. Apples last year were badly infested with American blight; it is again in evidence on some trees, but the attack is not so severe as the trees were well sprayed in late winter with Karbo Killegg; apart from this, the trees seem cleaner than usual. The soil here varies from light gravelly to medium loam. *George H. Head, Fulwell Park Gardens, Twickenham.*

SURREY.—Apples are a good crop in this district, although some trees are rather thinly fruited; Pears and Plums are almost total failures. Small fruits were plentiful, with the exception of Strawberries, which have been allowed to run out, but I am hoping to have a crop next year from fresh stock. The total rainfall up to July 12 was only 4·67 inches. *Grigor Roy, Bevenden Gardens, Oxshott.*

—— The fruit crops around this neighbourhood are much under the average, especially in regard to Apples. There was plenty of blossom, but it was small and weak and never opened properly. The trees are clean and have made good growth, so that, given a sunny autumn, there may be good crops of fruits next year. Peaches and Nectarines have never been better or the trees cleaner. Pears, Raspberries, Currants and Strawberries are our best crops. Apples, Plums and Gooseberries are failures. *F. Jordan, Ford Manor Gardens, Lingfield.*

——The fruit crops in general in this neighbourhood looked remarkably well and promising up to April 20; after this date we were overtaken by one of our cold waves, which lowered the temperature below freezing point on seven consecutive nights, followed by four milder days, then frost again on May 1. This, of course, caused a sad set-back to all hopes of a great fruit crop, especially of Apples. Whole bunches of flowers fell, before even showing colour, from the trees of some of the best varieties, *i.e.*, Bramley's Seedling, Annie Elizabeth, Newton Wonder, Belle de Boskoop, Beauty of Kent, Dumelow's Seedling, Rev. W. Wilks, Warner's King and many others; Blenheim Pippin, Cox's Orange Pippin, Allington Pippin, Charles Ross, James Grieve, Gravenstein and Ribston Pippin were less damaged. *G. Carpenter, West Hall Gardens, Byfleet.*

(*To be continued.*)

HOME CORRESPONDENCE.

Astilbe simplicifolia.—I was particularly interested in the beautiful Supplement Plate illustrating this plant, which appeared in *The Gardeners' Chronicle* for August 24. This delightful Astilbe first appeared in my nurseries at Brantwood, Southport, as a chance seedling, and I gave it a royal welcome owing to its pleasing appearance. In the second year after its appearance it began to flower, and at once I thought it must be a Spiraea or some near relative. I am still under the impression that it first made its appearance under the name of Spiraea. If I mistake not, I had a visit at that particular time from Mr. Clarence Elliott, to whom I sold the plant, for what I considered at the time to be a fabulous price—a guinea! The following year I received a consignment of plants from the Yokohama Nursery Company and to my great joy and to my surprise found enclosed a few seedling plants of what was then known as Spiraea simplicifolia. I must have sent some of the plants to Mr. Irving, at Kew, and I believe he was able to raise a few seedlings of this most dainty little stranger. I think it was in the following year that I succeeded in importing a number of plants of it. This would be about the year 1910, at which time I was also able to offer another charming little plant, Jankaea radicans, which is but seldom seen in collections. *W. H. Stansfield, Southport.*

Hardiness of Gladiolus species.—It was rather surprising to read of Mr. Arnott's experience with Gladiolus byzantinus (recorded on p. 204), more especially as I have seen it flourishing in a light, sandy soil so far north as Aberdeen, where it withstands the winter well. I made two plantings of this species here in London. The first batch was placed in the ground at Christmas, 1928, and the second in April, 1929, about the third week in the month. At the time of the severe frosts in February and March, 1929, the first batch had made no growth, and came through quite safely with only about two inches of soil to cover them. Both batches flowered simultaneously about June 24. In September, 1928, I planted some corms of G. cardinalis in the open ground, and these were about nine inches high at Christmas, 1928, but the frosts, coming later, destroyed the whole batch. A second planting made at Christmas, 1928, came through the winter quite safely. *Robert H. Jeffers.*

The Effects of the Drought.—The symptoms which Mr. H. H. Cook describes (p. 136) as affecting Apples of certain varieties growing in grass are simply those of nitrogen starvation, helped, of course, by the drought. Last year many of my trees in grass looked just as poor as he describes. This year, after a generous spring application of a quick-acting nitrogenous fertiliser, they are carrying dark green leaves and a heavy crop of fruits of normal size, in spite of severe drought. Cox's Orange Pippin, in these conditions, is making a lot of growth, and promises to swell its fruits to more than average size. *Market Grower.*

SOCIETIES.

ROYAL HORTICULTURAL.

September 19 and 20.—The first of the series of four Autumn Shows which, this year, are to take the places of the usual one comprehensive show, was held in the Society's halls, Westminster, on these dates. The innovation is of the nature of an experiment, and until its completion, no one can judge of its success. Besides dividing the conventional Autumn Show into sections there seems to be an attempt at discovering whether there is a preference on the part of the exhibitors and the other Fellows for any particular pairs of days of the week. The present show has been held on a Thursday and a Friday, the next is to be on a Wednesday and Thursday, while the third will occupy the time-honoured Tuesday and Wednesday. There was no dearth of exhibits last week, for both halls were filled, and the Orchid annexe and Tea annexe were requisitioned, but it seemed to us that the attendance was not quite equal to that of last year's Autumn Show. The show was "chiefly for open-air plants and Roses," so there were seasonable hardy border flowers in abundance, a goodly number of small rock gardens and Water Lily pools surrounded by bog plants, gorgeous displays of Dahlias, masses of delightful, fragrant Roses and, no doubt admitted by the qualifying "chiefly," magnificent pot-grown, tuberous-rooted Begonias. The Committees met as usual. The Orchid Committee recommended one First Class Certificate and four Awards of Merit to novelties, and the Fruit and Vegetable Committee found a new dessert Apple to be of outstanding merit. In view of the floral importance of the show, the novelties before the Floral Committee were disappointing, for there were only three which could be considered worthy of award, while several others were selected for trial at Wisley. The Joint Dahlia Committee again selected a number of novelties for trial.

Orchid Committee.

Present: Mr. Frederick J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Secretary), Prince Shimadzu, Mr. R. G. Thwaites, Mr. T. Armstrong, Mr. J. C. Cowan, Mr. Fred. K. Sander, Mr. J. E. Shill, Mr. A. Dye, Mr. Charles H. Curtis and Mr. H. G. Alexander.

First Class Certificate.

Potinara Dorothy, Dell Park var. (*Sophro-Laelio-Cattleya Prince Hirohito × Brasso-Laelio-Cattleya maculata*).—A gorgeous and glorious Orchid of oriental splendour. The flower shown was of large Cattleya size, with broad petals and fairly wide sepals. The colour in all these segments is rich yellow with a tinting of orange-yellow towards the margin in the case of the petals, and towards the tips of the sepals. The wide and frilled lip is of brilliant reddish-carmine, with exquisite gold veining over the orange-tinted central area and throat. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Awards of Merit.

Laelio-Cattleya Profusion, Stonehurst variety (*L.-C. Serbia × C. Hardyana*).—There is a profusion of Profusions, and although the Stonehurst variety has been surpassed in form by varieties previously certificated, it is of fine colour. The sepals and petals are rich deep purplish-mauve, while the bold, frilled lip is bright, deep royal-purple with a gold-veined throat. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Laelio-Cattleya Ishtar var. magnifica (*L.-C. Sargon × C. Fabia*).—A handsome form of fine substance, with purplish-mauve sepals and petals, and a crimson-shaded, gold-veined, purple lip. Shown by Robert Paterson, Esq.

Cattleya Mimosa var. Primrose Queen (*C. Venus × C. Triumphans*).—A pretty variety in which the sepals and petals are light yellow, with primrose shading down the centre of the latter and at the bases of the former. The lip is dull purple, shaded with crimson. Shown by Messrs. Cowan and Co.

Gongora maculata.—A very charming form of this old Orchid. The long, red-stemmed, pendant spike carried thirty-three elegant little flowers which are yellow, heavily dotted with dark brown. The pedicels of the flowers are red. This appears to be a variable South American species as shown by the figures in *Bot. Mag.*, t. 3,687 and t. 7,530. Shown by Messrs. Charlesworth and Co.

There were no groups on this occasion, but Messrs. Armstrong and Brown showed Cattleya Gisie var. Golden Queen (C. Dionysius × C. Dowiana var. aurea); this was not well-named, however, as the sepals and petals were pale cream, tinted with greenish-yellow. Laelio-Cattleya Senator, Brownland's var., with four flowers, was shown by S. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. A. Turner, Mr. C. F. Langdon, Mrs. Wightman, Mr. B. R. Long, Mr. M. C. Allwood, Mr. D. Allan, Mr. J. B. Riding, Mr. J. T. West, Mr. R. Findlay, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. G. W. Leak, Mr. H. R. Darlington, Mr. Courtney Page, and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. C. T. Musgrave (in the chair), Mr. G. Reuthe, Mr. W. G. Baker, Mr. G. Harrow, Mr. Amos Perry, Mr. T. W. Taylor, Mr. F. G. Preston, Mr. R. C. Notcutt, Mr. R. W. Wallace, Sir William Lawrence, Bt., Mr. George Yeld, Mr. W. J. Bean, Mr. G. W. E. Loder, Hon. H. D. McLaren, Mr. E. A. Bowles and Mr. N. K. Gould, Secretary.

Awards of Merit.

Lapeyrousia grandiflora.—This showy little bulbous plant was discovered by Sir John Kirk in Zambesia in 1858, and figured in *Bot. Mag.*, t. 6,929. It is a cool greenhouse plant. The bright reddish-terra-cotta flowers have velvety-crimson markings on the three, shorter lower segments and, at times, on one or two of the upper segments (See Fig. 116, p. 239). Shown by Mr. Amos Perry.

Lilium philippinense var. formosum, Price's variety.—A graceful Lily which has small leaves and relatively large trumpet-shaped, fragrant flowers of milky-white colour stained with red along the outsides of the segments. This plant received the award on September 10 last. Shown by E. M. Preston, Esq. (gr. Mr. C. F. Wood), The Warren, Hayes, Kent.

Chrysanthemum Mrs. W. D. Cartwright.—An incurving Japanese variety of good market size and bright yellow colour.

Chrysanthemum Kingcup.—A small Japanese variety of rich yellow colour. Both varieties were shown by Mr. H. Shoesmith, junr.

For Trial at Wisley.

Aster Gayborder Blue.—A semi-double, blue Novi-belgii variety. Although decorative in the border, the flowers curl up when cut. Shown by the Gayborder Nurseries.

Aster Bessie Chaplin.—A large-flowered, erect, Amellus variety of medium blue colour. Shown by Mr. T. Bones.

Aster Pink Pearl.—A large, semi-double, pale pink Novi-belgii of considerable beauty. Shown by Mr. E. Ballard.

Aster Mrs. Gladys Forbes.—A large, single, pale mauve Amellus variety. Shown by Mr. T. Bones.

Joint Dahlia Committee.

Present: Mr. H. B. May (in the chair), Mr. J. F. McLeod, Mr. J. Cheal, Mr. A. Turner, Mr. R. Fife, Mr. J. T. West, Mr. J. B. Riding, Mr. J. Emberson, Mr. W. H. Johns, Mr. A. Vasey and Mr. D. Campbell.

New Dahlias.

The Joint Dahlia Committee selected the following varieties for trial at Wisley.

Rebel.—A large Cactus variety of rose-maroon colour. This, and the following variety, were shown by Messrs. J. Stredwick and Son.

W. F. Balding.—A large Decorative variety of pale amber colour suffused with apricot.

Margate Star.—A shapely yellow Star variety heavily flushed with rosy-purple except at the base of the ray florets. This and the following three varieties were shown by Messrs. J. Cheal and Sons.

Hadley. — An uncommon, small Paeony-flowered variety. The pointed florets are of Indian-red colour, flushed with red-maroon.

Mysore.—A small Paeony-flowered variety of light rosy-mauve colour.

Nagpur.—A bright scarlet, small Decorative variety.

Eda.—A very pretty, small Paeony-flowered variety of orange shading.

Pauline—An orange-terra-cotta, small Paeony-flowered variety. This, and the above, was shown by Messrs. Burrell.

Dahlias.

Dahlias contributed largely to the bright display in the new hall, where the walls were lined with magnificent groups of these popular seasonable flowers.

In his grand collection of large-flowered sorts, Mr. J. B. Riding showed Queen of the Garden Beautiful, Lady Stonehaven, W. D. Cartwright, Lotus, Amulet, Grace Curling, Jane Cowl, Titan, Berengaria, Golden Sun, Neptune, Adler and Carnival in perfect condition, while special features in the lovely group from the King's Acre Nurseries were Golden Sun, W. D. Cartwright, Talisman, Trentonian, R. E. Ludwig, Berengaria and Andreas Hofer, together with several choice Collerette, Pompon and other types.

Messrs. H. J. Jones had a charmingly arranged group in which were lovely sheaves of Tommy Atkins, Hera, Mr. T. Hay, V.M.H., Jersey Beauty, Polar Bear and W. D. Cartwright, while other good sorts were Canberra, Doris Trayler, J. L. Crowther, Mabel Lawrence, Andreas Hofer, Golden Sun, Talisman and Homeric; choice Pompon varieties included Johnnie, Glow, J. van Oitters and Ideal.

Messrs. Jarman and Co. showed Cactus varieties chiefly, their outstanding sorts being A. E. Amos, Ballet Girl, Margaret, Harry Strutt, Ambassador, Mary Segar, Mary Purrier, Mary Murray and J. Emberson; Mr. S. J. Goodliffe showed many choice Dahlias in association with several good Michaelmas Daisies; Messrs. Carter Page and Co., Ltd., were responsible for a handsome group of many popular sorts, and so also was Mr. J. T. West.

Messrs. Dickson and Robinson had a well-finished and very decorative group of Dahlias, edged with various Pompon sorts, outstanding Dahlias in their group being Espoir, W. D. Cartwright, W. V. Goethe, Yellow Perfection, Réne Cayeux, Rapallo and Cayclerc.

At the far end of the hall an enormous bank of blooms was set up by Messrs. Dobbie and Co., Ltd., who gave special prominence to their so-called Orchid-flowered Dahlias, in various bright colour shades; Dream, Flamingo, Fawn, Redpole and Mavis were notable. These were grouped in the centre of the display and were flanked with attractive sheaves of grand blooms of many other Dahlias, of various types.

Messrs. J. Cheal and Sons, Ltd., laid out an original and quite effective display of Dahlias in the form of a more or less formal garden. There was a central mound of various large-flowered Decorative sorts, and smaller beds of choice Star, Cactus, Paeony-flowered and Collerette varieties, with an edging of Mignon Dahlias in variety.

Messrs. James Stredwick and Son staged many specimen blooms of choice, large-flowered Dahlias; while Mr. H. Clarke and Messrs. G. and A. Clarke, Ltd., also Messrs. W. Wood and Son, Ltd., staged collections of varying size and merit.

Messrs. W. Treseder, Ltd., showed grand blooms of Rapallo, F.T.D., Vesuvius, Mabel Lawrence, Halvella and Jersey Beauty, among others, in a particularly bright group, next to which was another bank of Dahlias set up by Mr. H. Woolman, such large-flowered sorts as Trentonian, Mayflower, Grace Curling, W. D. Cartwright and Joyce Goddard being of exceptional quality.

Michaelmas Daisies.

Owing to the continued dry weather, Michaelmas Daisies were not so much in evidence at this show as might have been expected, and there were few exhibits of note.

Certainly the best, although badly placed, was the tall rectangular pyramid set up by Messrs. W. Wells, junr. It contained floriferous sprays of many bright varieties, notably Empress of Colwall, Barr's Pink, Royal Blue, Countess, October Dawn, Maid of Athens, Owen Wells, and several varieties of the Amellus section.

Mr. H. Hemsley associated perennial Asters with Dahlias and Sidalceas, his best sorts being Mrs. J. Raynor, Royal Blue, Barr's Pink and Percy Ballard; while Mr. F. Rich showed good sprays of King George, Elizabeth Leiman and Herman Lous, of the Amellus section, in association with such popular tall-growing sorts as Ethel Ballard, Empress of Colwall, Grey Lady and Barr's Pink.

Mr. Ernest Ballard, well-known as a raiser of many fine Michaelmas Daisies, had a charming group of these flowers. He had corner pillars of October Dawn and Snowdrift; Royal Blue and Nancy Ballard; Maid of Athens and Empress of Colwall; and Edith Ballard and Mrs. George Monro. In the centre were dainty sprays of Silver Spray, of the ericoides section, and the groundwork of the group consisted of masses of Pink Pearl, Countess, Little Boy Blue, Queen of Colwall, Snow Sprite, Rosette and others. A very charming display.

Mr. T. Bones set up a lovely bank of many good sorts, and besides many Amellus varieties he had lovely vases of Maggie Perry, Ethel Ballard, Maid of Athens, Daphne, Pink Perfection, Viscountess Gladstone and Snowdrift.

Messrs. W. Cutbush and Son, Ltd., staged an extensive group of seasonal herbaceous flowers, chief among which were the Michaelmas Daisies, notably the varieties Surprise, October Dawn, Ethel Ballard and Snowdrift.

The Gayborder Nurseries were also responsible for the setting up of a charming group of perennial Asters, their sprays of Gayborder Blue (new), Barr's Pink and Countess being notable; while among varieties of Aster Amellus their best were King George, Mrs. A. H. Wiggin and Perry's Favourite. In association with Heleniums, Gaillardias and other seasonable flowers, Messrs. G. Jackman and Son showed good Michaelmas Daisies in Kate Bloomfield, Mons, October Dawn, Dick Ballard, Woking White, Royal Blue and Robinson V.C.

The group of herbaceous subjects from the Little Munsden Nursery contained several good perennial Asters, while the chief varieties in the mixed group staged by Mr. R. J. Case were King George, Nancy Ballard and Little Pink Lady. Messrs. W. Keep and Co. arranged charming sprays of Dick Ballard, Rose Queen and King George, the last-named especially good, in association with Heleniums in variety and other herbaceous subjects. In conjunction with Gladioli, Liatris, Gaillardias, etc., Messrs Rich and Cooling, Ltd., showed good sprays of numerous Michaelmas Daisies, including October Dawn, Empress of Colwall, Snowdrift and Peggy Ballard; while the Central Garden Supplies also set up a small group in which these popular flowers predominated. Not the least attractive of the groups staged in the new hall was that tastefully arranged by Messrs. Barr and Sons, who had grand sprays of the Earlham Montbretias, in several varieties, a speciality of this noted firm; lovely inflorescences of Lilium sulphureum and various herbaceous subjects, chief among which were Michaelmas Daisies in grand condition, a few of their varieties being Countess, Barr's Pink, naturally; Grey Lady, Rachel Ballard, October Dawn, Dick Ballard, Little Boy Blue, very fine; and Royal Blue. A very attractively arranged group.

Messrs. G. Bunyard and Co., Ltd., had a charmingly arranged bank of herbaceous subjects, chief among which were Michaelmas Daisies, including such good varieties as Little Boy Blue and Royal Blue, with several representatives of the Amellus and ericoides sections; the Heleniums, Kniphofias, Coreopses and Scabiosa caucasica also proved attractive in this collection.

In a charmingly arranged rectangular group, Mr. Gavin Jones associated such perennial Asters as King George, Ultramarine, Dick Ballard and Barr's Pink, with Heleniums, Sedum spectabile, Gaillardias, Liatris, Achillea filipendulina, Rudbeckia purpurea and Gypsophila paniculata var. Bristol Fairy, to produce a very bright effect.

Roses.

These were greatly in evidence in the old hall, the walls of which were lined with many lovely groups.

First on the left hand side of the entrance was an artistically arranged bank of good blooms by Messrs. Ben. R. Cant and Sons, Ltd., whose baskets of Elsie Poulsen, K. of K., Mrs. Henry Bowles, and Mrs. Beatty were particularly charming. Next to this group was one by Messrs. R. Harkness and Co., who made a special feature of K. of K., and showed good blooms of many popular sorts, especially Marcia Stanhope, Mrs. Charles Lamplough and Madame Butterfly.

Messrs. Chaplin Bros. had grand pillars of Betty Uprichard, Dame Edith Helen, Conqueror, Los Angeles and Windsor in their attractive display, while prominent sorts in the bright and artistically arranged group by Messrs. Alex. Dickson and Son, Ltd. were Shot Silk, Dame Edith Helen, Flamingo and Mabel Morse. The Dowty's Rosery group contained many good blooms of popular sorts, as also did Messrs. Walter Easlea and Sons Ltd's.

Mr. J. C. Allgrove and Messrs. George Bunyard and Co., Ltd., made special features of fruiting sprays of various Rosa species, the former showing R. Fargesii, R. pomifera and R. Moyesii, and the latter R. complicata, R. Spathiana, R. glutinosa, R. villosa and R. rubrifolia. Messrs. A. Reeves and Co. had lovely vases of Coral Queen and Little Dorrit, a charming cerise, dwarf Polyantha variety.

In the bright display arranged by Messrs. D. Prior and Sons, the best of many good sorts were Etoile de Hollande, Rev. F. Page Roberts, Golden Ophelia and Mrs. Beatty; Mr. T. Hancock showed the richly-coloured variety Charming Princess, while outstanding features in Mr. Elisha J. Hicks's group were the pillars of Angele Pernet, Ophelia, Los Angeles, Shot Silk and Etoile de Hollande. Good sorts, among many, in Mr. J. H. Pemberton's nicely arranged group were the single Mermaid, Madame Butterfly, K. of K., and Pax.

Mr. George Prince had a nicely arranged collection of bright, clean blooms, his chief feature being the *Daily Mail* scented Rose, other prominent sorts including Betty Uprichard, Independence, Elizabeth Arden, Los Angeles and W. F. Dreer.

Size and cleanliness of the individual blooms were the notable features in the grand display by Mr. Thomas Robinson, who was awarded the Wigan Challenge Cup. Every bloom was of large size and of perfect shape, the chief sorts being Mabel Morse, Etoile de Hollande, Mrs. A. R. Barraclough, Dame Edith Helen, Mrs. Herbert Stevens and Miss C. E. van Rossem.

The Irish-grown Roses staged by Messrs. S. McGredy and Son were, as usual, richly and brightly coloured, and remarkably clean. The collection embraced a very large number of varieties, among the best being Madame E. Herriott, McGredy's Ivory, Cherry, Emma Wright, Golden Emblem, Margaret McGredy, Mrs. Charles Lamplough, of grand form; Frau Karl Druschki, and Portadown Bedder, other sorts of comparatively recent introduction, and staged separately, being Rose Berkeley, Lady Leslie, Marian Cran and Doris Trayler.

Messrs. Thomas Smith and Son made special features of Covent Garden, Betty

Uprichard, Madame E. Herriot, Margaret Ann Baxter and Lady Inchiquin in a bright group, while besides several good dwarf Polyantha varieties the collection from the Stanway Rose Gardens contained especially good blooms of Mabel Morse, Mrs. Beatty and Angele Pernet. Messrs. Wheatcroft Bros. made a special feature of The Princess Elizabeth, of which they showed many good blooms in association with other popular sorts.

Messrs. Allens set up a bright bank of Roses, while prominent in the extensive collection staged by Messrs. Hewitt were Dame Edith Helen, Mrs. Herbert Stevens, Queen Alexandra and Mrs. Henry Morse. Messrs. A. Warner and Son also staged lovely vases of good blooms in great variety.

CHRYSANTHEMUMS.

Although Chrysanthemums were not numerous, they yet were quite a feature of the show, especially the grand group set up by Mr. J. W. Forsyth, who showed richly-coloured and beautiful blooms of Mrs. Phil Page, Hollicot Yellow, Bronze Early Buttercup, Winnie Cawden, R. C. Callicott, Sunkist, Crimson Circle, Shirley Pride, Mrs. Jack Pearson, Cranfordia and Bronze Betty Spark, to mention but a few of the most prominent.

Numerous decorative Chrysanthemums were staged in a charming group from the King's Acre Nurseries, notable among them being Crimson Circle, Goldfinder, Bronze Early Buttercup, Martin Reed, Mrs. J. Pearson and Harvester; while outstanding in the collection from the Gayborder Nurseries were Phoenix, Bronze Early Buttercup, Pink Dame and Crimson Circle.

In the bright and tastefully arranged display by Messrs. K. Luxford and Co., there were grand blooms of Pink Delight, September Glory, Crimson Circle, Elsenham White, very fine; Goldfinder, Almirante, Harvester, Shirley Pride and Mrs. Jack Pearson; while the best in the small collection staged by Mr. H. Woolman were Nesta, Bronze Early Buttercup, The Provost, Cissbury White, Golden Security, K. Osborne, Brightness and F. J. Woods.

HARDY BORDER FLOWERS.

An attractive display of seasonal border flowers was made by Messrs. George Jackman and Sons, with various Heleniums, Rudbeckias, Physalis Bunyardi and a quantity of Gaillardia Tangerine. On a long stretch of tabling, Messrs. B. Ladhams, Ltd., grouped many of their valuable tall-growing Lobelias, particularly the varieties Shirley Crimson, Velvet, Mrs. Humbert and Purple King, with the best Heleniums, Gaillardias, Sidalceas, Trollius Golden King, Lavatera Olbia and many other plants. Mr. G. Reuthe associated Lilium tigrinum with Physalis Bunyardi, Eupatorium ageratoides, Eryngiums and many Michaelmas Daisies.

In the Orchid Annexe the Central Gardens Supplies had an interesting selection of flowers which included several showy Helianthuses and the allied Heleniums, Colchicums and Michaelmas Daisies. Tritomas of merit, Sidalceas, Iceland Poppies, Michaelmas Daisies and Gladioli were well shown by Messrs. Harkness and Sons, while Messrs. E. J. Redgrove and Son set up very good Delphiniums, with Tritomas, early-flowering Chrysanthemums and Michaelmas Daisies. The extensive collection of border flowers arranged by Messrs. M. Prichard and Sons included particularly good varieties of Anemone japonica, herbaceous Phlox, Poterium obtusum, Pyrethrums, Heleniums and Tritomas. Echinacea purpurea, Coreopsis grandiflora and Heleniums were prominently displayed with Michaelmas Daisies by Mr. A. Miles.

Very good spikes of late Delphiniums, especially the varieties Princess Elizabeth, Rose Marie, Nora Ferguson, Welshman and Theodora, were staged by Messrs. Hewitts. Messrs. G. Gibson and Co. had a large stand of a brilliant orange-coloured Iceland Poppy with their collection of dwarf Junipers and Ericas and alpines in pots. Phlox maculata var. Alpha, several very good Montbretias, Scabious and Colchicums were set out by Messrs. Oliver and Hunter, who also showed several flowers of the fragrant Lilium philippinense formosum, Price's variety.

Several robust varieties of Antirrhinum, shown by Messrs. W. H. Simpson and Son, included, in The King, Aurore and White Wings, three of the desirable intermediate type. They also had a very good selection of Montbretias. The Hon. Mrs. Montagu also had some good Montbretias which included the varieties Jessie, Mrs. E. S. Montagu and R. C. Notcutt, of deep colouring, and Montagu, yellow; Lady Wilson, pale orange; and Queen Alexandra, medium yellow. Messrs. Isaac House and Sons had such varieties as Clive Greaves, blue; Highgrove, pale lilac; and Leonard, dark blue, among their valuable Scabiosa caucasica forms, and some Tritomas. Mr. James MacDonald made one of his fascinating gardens of lawn and other grasses in the new hall.

A very good collection of herbaceous Phloxes, shown by Messrs. E. F. Fairbairn and Sons, included Sir Douglas Haig, Veronica, Purple Robe, Bright Eye and Joan Fairbairn. Messrs. Blackmore and Langdon staged many fine Phloxes, particularly Rynstroom, Evelyn, Daily Sketch, Viking and Firebrand. In their collection of herbaceous Phloxes, Messrs. John Forbes, Ltd., showed strong trusses of Border Beacon, Mrs. G. McBeth, and Sir T. Henderson. They also staged good Pentstemons and Dahlias.

On a large floor space, Messrs. Wallace and Co. showed a large quantity of Lilium tigrinum, Lilium sulphureum, Lilium auratum var. platyphyllum and several good varieties of Lilium speciosum. Below the Liliums, they arranged vases of Montbretias and Michaelmas Daisies. Mr. Amos Perry also showed varieties of Lilium speciosum and Lilium Henryi with Coreopsis grandiflora, Perry's var. and Aster Amellus varieties.

In the old hall, Mr. Amos Perry set out one of his excellent water and bog gardens. In this he had a great variety of aquatics, grasses, reeds and rushes, Cyperus gracilis, Lysimachias, Nelumbiums, and the yellow Xanthosoma violaceum which recently received an Award of Merit. Messrs. Hillier and Sons also made a pool in which they placed some good Nymphaeas, and around it they showed Zauschneria californica, Artemisias, Pontederia cordata, Hypericum chinense and Yuccas. Messrs. L. R. Russell, Ltd., had a small, raised pool with a few Nymphaeas, a rock garden furnished with Sempervivums and, at one end, a good collection of hardy Fuchsias in small pots.

An extensive collection of Gladioli, principally of the large-flowering sorts, was arranged by Messrs. R. H. Bath, Ltd. This included very good spikes of Dawn, Mrs. Frank Pendleton, Nimrod, Purple Glory, Chateau Thierry, Byron L. Smith, Floral, Rose Precoce, J. T. Pirrie and Captain Boynton. The Orpington Nurseries showed such Gladioli as Willy Wigman, America, Van Beieren, Chris and Czar Peter in round baskets, while Messrs. Daniels Bros., Ltd., associated their Gladioli with Montbretias and many flowers of Gaillardia Tangerine.

ROCK GARDENS.

Dwarf trees and shrubs were the principal feature of most of the small rock gardens, which were made in the old hall. This was particularly interesting as, we believe, the exhibitors in the new Horticultural Hall were informed by an official of the Society that, as the next show was especially for trees and shrubs, none would be allowed on the present occasion. This rule was enforced so strictly that exhibitors were compelled to remove small sprays of shrubs which they had used as backing to Dahlias and other flowers. Objection does not seem to have been raised to the similar use of greenhouse plants, principally Maidenhair Ferns, for which there is also a special occasion.

However, the dwarf Conifers and various shrubs of the rock gardens were typical and appropriate to their positions, and we have no doubt that, while they must have offended the official eye, the visitors and exhibitors approved. With their dwarf Conifers, Heaths and the like, Messrs. M. Prichard and Sons planted Zauschneria californica, Colchicums, Campanulas, Cyclamens, Geums and Erigeron Ada Gray. Mr. E. G. P. Wood planted Delphinium sinense, Gazania splendens and other flowers below Cotoneaster horizontalis and by Juniperus Sabina var. tamariscifolia. He also had a model paved path.

Well placed boulders, colonies of dwarf, upright Irish Junipers, breadths of Colchicum Parkinsonii and Nierembergia rivularis were the chief features of the rock garden made by Mr. Clarence Elliott. In one nook he planted Buddleia variabilis var. nanhoensis and Zauschneria californica in another. Mr. W. E. Th. Ingwersen exhibited a rock garden of uncommon outline. He had many dark green Pinuses at the back and below planted various Colchicums, Sedums, dwarf Campanulas and Gentiana Farreri. Mr. P. Gardner had low groupings of Conifers and Heathers, with border plants and alpines. Messrs. John Scott and Co. filled a table space with Conifers, Barberries and alpines. Mr. Stephen Sims also showed Conifers and alpines.

An effective rock garden, planted chiefly with Heaths, including the new Calluna vulgaris var. flore pleno, Cotoneasters, Fuchsias, Potentillas, Saxifrages and Nierembergia rivularis, was made by Messrs. Maxwell and Beale. Messrs. G. and A. Clark, Ltd., showed various alpines in pots and, in another place, had fine spikes of Lilium tigrinum, with various Tritomas and other border flowers. In their small rock garden, the Cambria Nurseries planted suitable Conifers, Gentiana Farreri, Androsace lactea, Papaver alpinum and Dianthus Spark. Mr. J. Robinson showed herbaceous Phloxes, Golden Rod, Michaelmas Daisies and alpines.

A mossy bank was planted by Messrs. Backhouse, Ltd., with low Conifers and other effective shrubs, Campanulas, Sempervivums and Fuchsias. Messrs. Reamsbottom and Co. had many handsome flowers of their St. Brigid Anemones. The Misses Hopkins had a seasonable collection of good border flowers and alpines.

An informal rock garden provided a fitting place for the rock alpines which Messrs. Allwood Bros. term "Allwoodii alpinus." These compact little plants are stated to flower continuously from spring to winter, and when out of bloom the foliage alone is very attractive. The principal varieties were Ariel, blush-mauve; Pixie, fringed white; Tinkabell, pale pink; Oberon, cerise; and Titania, maroon.

BEGONIAS AND CACTI.

In the new hall, Messrs. Blackmore and Langdon exhibited a quantity of their magnificent double-flowered Begonias. As usual, the plants illustrated a first-rate strain and expert cultivation. The many flowers were of great size, perfect form and clear colours. The arrangement of the group was very pleasing. The principal varieties were E. J. Henderson, scarlet; Lord Lambourne, orange; Madame Louise Laroque, picotee-edged white; Mary Newman, yellow; Mrs. E. Ramsden, rose; Queen of the Belgians, pink; and Robert, deep crimson. Miss S. S. Thompson staged a very interesting collection of succulent plants. These were mostly small, but well-grown, specimens illustrating many genera and varieties.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. J. Cheal, Mr. H. S. Rivers, Mr. E. A. Laxton, Mr. F. Bostock, Mr. A. Poupart, Mr. E. Beckett, Mr. F. G. Treseder, Mr. A. W. Metcalfe, Mr. G. F. Tinley, Mr. A. Bullock, Mr. A. C. Smith, Mr. W. Poupart and Mr. A. N. Rawes, Secretary.

THE BUNYARD CUP.

At the meeting of this Committee on August 28 of last year, Messrs. Laxton Bros., Bedford, showed a new seedling Apple named Epicure, of such good quality that the Committee recommended it for the Bunyard Cup, subject to it being shown again this year, in accordance with the rules governing the bestowal of this award, to ensure its having maintained the high quality first evidenced. Specimens of this Apple were exhibited at the present meeting, when the Fruit and Vegetable Committee confirmed its previous high opinion of it and awarded it the Bunyard Cup, the award being subsequently confirmed by the Council. Apple Epicure has for its parentage the popular varieties Cox's Orange Pippin and Wealthy. The fruit is of medium size, rounded, with a shallow, closed eye and a slender stalk set in a rather deep cavity. The skin is yellowish-green flushed red; the flesh moderately firm and crisp, and the flavour rich and pleasantly sweet. Apple Epicure was illustrated in our issue of December 29, 1928, Fig. 228, p. 511.

A yellow-fruited Tomato named Primrose Bloom, exhibited by Dr. A. H. Williams, Horsham, was recommended for trial at Wisley.

Awards of the Council.

Wigan Cup.—For the best exhibit of Roses staged on an area not exceeding one hundred square feet. To Messrs. T. Robinson and Son.

Silver Cup.—To Messrs. S. McGredy and Son, for Roses.

Gold Medals.—To Messrs. R. H. Bath, Ltd., for Gladioli; Messrs. Blackmore and Langdon, for Begonias; Messrs. Alex. Dickson and Sons, Ltd, for Roses; Messrs. Dobbie and Co. Ltd., for Dahlias; Mr. J. B. Riding, for Dahlias; and to Messrs. T. Robinson and Son, for Roses.

Silver-gilt Lindley Medal.—To the Hon. Mrs. Montagu (gr. Mr. J. E. Fitt), for Montbretias.

Silver-gilt Flora Medals.—To Messrs. Dickson and Robinson, for Dahlias; Mr. J. W. Forsyth, for early-flowering Chrysanthemums; Mr. H. J. Jones, for Dahlias; Messrs. Keith Luxford and Co., for early-flowering Chrysanthemums; Mr. Amos Perry, for aquatic and waterside plants; Mr. George Prince, for Roses; and to Messrs. W. Treseder, Ltd. for Dahlias.

Silver-gilt Banksian Medals.—To Mr. T. Bones, for Michaelmas Daisies; Messrs. Chaplin Bros., for Roses; Messrs. Jarman and Co., for Dahlias; The King's Acre Nurseries, for Dahlias; Messrs. M. Prichard and Sons, for herbaceous plants; Messrs. J. Stredwick and Son, for Dahlias; Messrs. R. Wallace and Co., Ltd., for Lilies and other herbaceous plants; Mr. W. Wells, junr., for Michaelmas Daisies and other herbaceous plants; and to Mr. H. Woolman, for Dahlias and early-flowering Chrysanthemums.

Silver Flora Medals.—To Messrs. Barr and Sons, for Montbretias, Michaelmas Daisies and other herbaceous plants; Messrs. Ben. R. Cant and Sons, for Roses; Messrs. Carter Page and Co., Ltd., for Dahlias; Dowty's Rosery, for Roses; Mr. Gavin Jones, for herbaceous plants; Messrs. B. Ladhams, Ltd., for Lobelias and other herbaceous plants; Mr. J. H. Pemberton, for Roses; Messrs. M. Prichard and Sons, for rock garden plants; Messrs. D. Prior and Sons, for Roses; Messrs. L. R. Russell, Ltd., for water and rock garden plants; and to Mr. J. T. West, for Dahlias.

Silver Banksian Medals.—To Mr. J. C. Allgrove, for Roses; Messrs. Allwood Bros., for Pinks and Border Carnations; Messrs. Bakers, Ltd., for herbaceous plants; Mr. E. Ballard, for Michaelmas Daisies; Messrs. G. Bunyard and Co., Ltd., for Asters and other herbaceous plants; Messrs. J. Cheal and Sons, for Dahlias; Messrs. W. Easlea and Sons, for Roses; Mr Clarence Elliott, for rock garden plants and dwarf Conifers; Messrs. E. F. Fairbairn and Sons, for Phloxes; Messrs. J. Forbes, Ltd., for Phloxes, Pentstemons and Dahlias; The Gayborder Nurseries, for Michaelmas Daisies; Messrs. Harkness and Sons, for herbaceous plants and Gladioli; Messrs. R. Harkness and Co., for Roses; Mr. H. Hemsley, for Dahlias and hardy flowers; Messrs. W. Hewitt and Co., Ltd., for Roses; Messrs. W. Hewitt and Co., Ltd., for Delphiniums; Mr. Elisha J. Hicks, for Roses; Messrs. Isaac House and Son, for Scabious and Kniphofias; Mr. W. E. T. Ingwersen, for rock garden plants and dwarf Conifers; Messrs. G. Jackman and Son, for herbaceous plants; Mr. Jas. MacDonald, for a grass garden; Messrs. Maxwell and Beale, for rock garden plants; Messrs. Oliver and Hunter, for herbaceous plants, bulbous and other rock garden plants; Messrs. Rich and Cooling, for herbaceous plants; Messrs. T. Smith and Sons, for Roses; The Stanway Rose Gardens, for Roses; Miss S. S. Thompson, for Cacti; Messrs. Warner and Son, for Roses; Messrs. Wheatcroft Bros., for Roses; and to Messrs. Wm. Wood and Son, Ltd., for herbaceous plants.

Flora Medals.—To Messrs. A. J. Allen and Co., for Roses; Mr. R. J. Case, for herbaceous plants; Mr. A. Miles, for herbaceous plants; Messrs. W. H. Rogers and Son, Ltd., for rock garden plants and shrubs; and to Mr. G. E. Welch, for rock garden plants.

Banksian Medals.—To Messrs. Backhouse Nurseries, for rock garden shrubs and plants; Messrs. G. and A. Clark, Ltd., for herbaceous plants; Mr. H. Clarke, for Dahlias; Messrs. W. Cutbush and Son, Ltd., for Michaelmas Daisies and Dahlias; Mr. R. Gardner, for rock garden plants; Messrs. G. Gibson and Co., for rock garden plants and dwarf shrubs; Mr. S. J. Goodliffe, for Dahlias and herbaceous plants; Messrs. Hillier and Sons, for water and rock garden plants; Messrs. W. Keep and Co., for herbaceous plants; The King's Acre Nurseries, for early-flowering Chrysanthemums; The Little Munden Nursery, for herbaceous plants and Dahlias; the Orpington Nursery Co., for Gladioli; Mr. Amos Perry, for herbaceous and bulbous plants; Messrs. E. J. Redgrove and Son, for herbaceous plants and Gladioli; Mr. G. Reuthe, for herbaceous and rock garden plants; Mr. F. Rich, for herbaceous plants; Messrs. J. Robinson and Sons, for rock garden and hardy plants; Messrs. W. H. Simpson and Sons, for Antirrhinums and Montbretias; Messrs. Tuckers, Ltd., for herbaceous and rock garden plants; Mr. Charles Turner, for Dahlias; Mr. G. E. P. Wood, for rock garden plants; and to Mr. Wm. Yandell, for Dahlias.

ASSOCIATION OF PARKS AND BOTANIC GARDEN SUPERINTENDENTS.

About thirty members of the North-western Branch of this Association paid a visit to Blackburn on Saturday, September 14. The party was met by Mr. E. Winsor, Superintendent of Parks, and proceeded to the Town Hall, where they were joined by several members of the Blackburn Parks Committee, and a motor-coach was kindly provided by the Parks Committee. Arriving at the main entrance to Corporation Park, on Preston New Road, the party first inspected the beautifully laid-out Garden of Remembrance and War Memorial situated just within the entrance. Corporation Park lies on the hillside above the town, and is about sixty acres in extent. It is a very fine example of a natural park, and the landscape gardener has taken full advantage of the natural features in planning the lay-out of the park. There is a rise from the main entrance to the highest point of three hundred feet whence an extensive view of the hills to the north and east of the town is obtained. An ornamental lake which was originally constructed as a service reservoir is situated near the centre of the park, and advantage has been taken of the stream flowing from the lake to construct a series of delightful waterfalls and rockeries in proximity to the main path, culminating in a pool in the Garden of Remembrance.

The conservatory and flower beds in the higher portion of the park were inspected as also were the bowling greens and hard tennis courts, the majority of which have been constructed under the supervision of Mr. Winsor during the past few years. A well conceived scheme at the top of the park which includes ten hard tennis courts together with a tennis pavilion and café was constructed at a cost of £17,000, chiefly by means of distress labour. The promenade, from which a good view of the remainder of the park and of the town is obtained, consists of a wide path running almost across the entire length of the park, and this is bordered on the lower side by a line of Lime trees and on the opposite side by a high bank planted chiefly with Rhododendrons. The general appearance of the park was favourably commented upon by the members of the party, and reflects great credit on Mr. Winsor and his staff.

The Cemetery was next visited, and the party then proceeded to Roe Lee Park, which has recently been laid out in connection with a municipal housing scheme. The absence of the usual boundary railings and entrance gates was noted, and members were pleased to observe that the residents in the adjoining houses evidently respected the confidence placed in them by the Parks Committee as there was no evidence of damage to plants or property. The last park to be visited was Queens Park, the chief features noted being the beautiful borders of mixed flowers near the entrance, and the bowling greens.

The party then adjourned to the Town Hall for tea, where the Deputy Mayor (Councillor Stanworth) said that it gave him great pleasure on behalf of the Parks Committee to welcome the members of the Parks Superintendents Association to Blackburn. He said the citizens of Blackburn were very proud of their parks and of the improvements carried out by Mr. Winsor. A vote of thanks to the Parks Committee for their hospitality and to Mr. Winsor and his staff was ably proposed by Mr. W. W. Pettigrew (Vice-President of the Association), and seconded by Mr. M. Morgan (Chairman of the North-western Branch).

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held at the Southport Flower Show on Wednesday, August 28, 1929, the members of Committee present were Messrs. Hy. Astley Bell (in the chair) J. B. Adamson, A. Burns, B. Collins, A. Coningsby, J. Evans, A. Keeling, G. V. Llewelyn, W. J. Morgan and H. Arthur (Secretary). Messrs. W. Mansell and E. Tack were invited to sit with the Committee.

First Class Certificates.

Brasso-Laelio-Cattleya Alfred Mollett var. *Vivid* (a Silver-Gilt Medal was also awarded); *Odontonia Etna* (*Miltonia chelseaensis* × *Odm. Ithone*); and *Vuylstekeara Rudra* var. *Atlas* (*V. Brewii* × *Odm. Prince Edward*). From J. B. Adamson, Esq.

Laelio-Cattleya Canberra var. *Sunset*. From Messrs. Charlesworth and Co.

Cattleya Vesta var. *Queen Mary*. From Mr. John Evans.

Cattleya Canberra var. *Prince of Wales*. From Messrs. Stuart Low and Co.

Awards of Merit.

Cypripedium Hurrellianum (*C. Curtisii* × *Argus*); *L.-C. Canberra* var. *Golden Queen*; and *L.-C. Modosa* (*L.-C. St. Gothard* × *C. Hardyana*); From Messrs. A. J. Keeling and Sons.

Odontoglossum crispum var. *Trianae magnificum*. From J. B. Adamson, Esq.

Odontioda Acis (*O. Ithone* × *Clovis*). From Messrs. Charlesworth and Co.

Cattleya Hardyana var. *alba exquisitum*. From Mr. John Evans.

Botanical Certificates.

To Miltonia Schröderiana; Bulbophyllum grandiflorum and Eria rhyncostyloides. From Messrs. A. J. Keeling and Sons.

Groups.

Gold Medals.—To J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool; Messrs. Charlesworth and Co.; Mr. John Evans; and Messrs. A. J. Keeling and Sons.

Silver-Gilt Medals.—To A. T. Cussons, Esq. (gr. Mr. A. Dalgleish), Kersal, near Manchester; and Messrs. Stuart Low and Co.

Large Silver Medal.—To Messrs. Sutton Bros.

At the meeting held at the Salford Flower Show, Buile Hill Park, on Tuesday, September 3, 1929, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, A Coningsby, A. Keeling and H. Arthur (Secretary). Messrs. J. Howes and C. F. Potts were invited to sit with Committee.

First Class Certificates.

Laelio-Cattleya Profusion var. illuminata (a Silver-Gilt Medal was also awarded); *L.-C. Hilary*; *L.-C. Chimera, Cattleya Monarch var. Salford, C. Lorna var. gigantea, and C. Etta var. The Pearl.* From Messrs. A. J. Keeling and Sons.

Vanda coerulea var. Salfordii. From J. McCartney, Esq.

Awards of Merit.

Laelio-Cattleya Profusion, Hey House var., and *L.-C. Profusion var. Cassie.* From J. McCartney, Esq.

Cultural Certificates.

To Mr. J. Howes, for Oncidium varicosum var. Rogersii and Maxillaria lepidota; Mr. C. F. Potts, for Vanda coerulea var. Salfordii.

Groups.

Gold Medals.—To J. B. Adamson, Esq., (gr. Mr. J. Howes), Blackpool, and Messrs. A. J. Keeling and Sons.

Large Silver-Gilt Medals.—To A. T. Cussons, Esq. (gr. Mr. A. Dalgleish), Kersal, Manchester; and J. McCartney, Esq. (gr. Mr. C. F. Potts), Hey House, Bolton.

At the meeting held on Friday, September 13, the members of Committee present were Messrs. J. B. Adamson (in the chair), A Burns, A. Coningsby, J. Evans, A. Keeling and H. Arthur (Secretary).

First Class Certificate.

Cattleya Wavriniana (*C. granulosa × gigas*). From Messrs. A. J. Keeling and Sons.

Groups.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, staged a group to which a Large Silver Medal was awarded. This contained Cypripedium Maudiae, C. Rossettii, C. Ernest Read and C. Curtisii; a fine batch of specimen plants Odontoglossum grande, was also included. Captain Horridge (gr. Mr. A. Coningsby), Bury, staged Cattleya Princess Royal, C. gigas and some hybrids. Messrs. A. J. Keeling and Sons showed Cypripedium The Major, C. Fairrieanum and C. Maudiae, Westonbirt var.; with Cattleya Hardyana var. alba. Mr. John Evans, Colwyn Bay, showed Oncidium incurvum and Cypripedium T. N. Abbott.

NATIONAL CHRYSANTHEMUM SOCIETY.

At the meeting of the Floral Committee held at the R.H.S. Hall, on Monday, September 23, thirteen novelties were brought forward and four awards were made, as follow:—

First Class Certificates.

Assurance. II. 1b.—A useful early Decorative variety of moderate size; the colour is glowing chestnut-red with dull gold tips to the central florets. The foliage is rather heavy for the size of the flowers.

Dart. II. 1c.—A very attractive flower, a trifle small, perhaps, but of good substance, with the central florets slightly cupped. The colour is bright chestnut, with gold tips. This and the foregoing was shown by Mr. J. A. Barrell.

Bridesmaid. II. 1b.—In this graceful variety the florets are pointed. The colour is salmon-pink with a fawny shading on the central florets. This and the following variety was shown by Mr. H. Shoesmith, junr.

Solidity. II. 1b.—A beautifully bright flower of good size and form. The colour is gold, faintly tinted with bronze. The florets are broad and slightly cupped at the ends; stem good.

ANSWERS TO CORRESPONDENTS.

Ampelopsis and Ivy on a Wall.—*W. E. P.* Of the two plants named, Ivy could do the greater damage, if moisture were to cause it to develop true roots in any of the seams between the masonry. The clinging roots of either could do little damage to bricks or stone; but if attached to mortar, some pieces of the latter might be hauled out, if the stems of Ampelopsis or Ivy were loose. Another kind of damage is done when either of these plants is allowed to choke the gutters at the eaves. Rain-water, in this case, sometimes runs down the interior of the wall, making it wet to the foundations. A redeeming feature of Ivy is that it is evergreen and keeps off rain in summer and winter. You do not state the nature of the damage, but in the case of mortar, it would be well to observe or ascertain whether or not the damage is done by pigeons, sparrows or other grain-eating birds, by picking out the mortar to get grit to grind their food. This has been done to a serious extent by pigeons on St. Paul's Cathedral, London.

Bouvardia Humboldtii.—*G. B.* This species of Bouvardia is easily propagated by means of cuttings of the young shoots inserted early in the year; they are best secured about three to four inches in length, and if placed in pots of sandy soil they root readily in a warm propagating case. They may also be readily increased by means of root cuttings, selecting the thickest roots for this purpose; these may be cut into pieces about one inch in length and inserted in pots of sandy compost, plunging the pots in a warm case. Plants may be grown in cold frames during the summer, or they may be planted out-of-doors in well-manured ground; this species, in fact, makes a good summer-bedding plant, for which purpose it is sometimes used in public parks. You could possibly procure it from Messrs. L. Russell, Richmond Nurseries, Sheen Road, Richmond, Surrey.

Buddleia alternifolia.—*A. S. W.* This species was introduced by Purdom and Farrer, about 1916, by means of seeds sent home from Kansu. Buddleia alternifolia was described and figured in *The Gardeners' Chronicle* of July 11, 1925 (p. 27, Vol. LXXVIII).

Grapes Failing.—*D. M.* It would appear that your Muscat of Alexandria vine has been overcropped; the fruits are suffering from what is commonly termed shanking. The Black Hamburgh Grapes are attacked by rust; red spider and green fly were also present. The Tomato was a double fruit. The drought is probably responsible for the bud-dropping of your Delphiniums.

Names of Fruits.—*W. S.* Plum Crimson Drop, probably.—*F. P.* Peaches: 1, Sea Eagle; 2, probably Thomas Rivers. — *Reading:* Apples: 1, Lady Sudeley (yellow); 2, Worcester Pearmain (red). — *A. J. R.* 1, Medlar, poor specimen, appreciated by some as desert when the fruits are in a state of decay; 2, Quince, used in the making of preserves and for flavouring Apples in cooking. —*D. A., Midlothian.* Peach, perished in post.

Names of Plants.—*W. H. S.* Cupressus sempervirens. — *J. T.* Larix europaea (Common Larch).—*J. C.* Oncidium incurvum. — *G.* 1, Dierama pulcherrima; 2, Funkia cordata; 3, Cynoglossum officinale; 4, Oxalis purpurea; 5, Sedum reflexum; 6, Alströmeria aurantiaca; 7, Linaria maroccana; 8, Clematis species, not recognised; 10, Erica vagans var. — *D. M.* 1, Calceolaria species, not recognised; 2, Cupressus orientalis var. aurea; 3, Golden Yew; 4, Lonicera nitida; 5, Polygonum sacchalinense; 6, Spiraea species; 7, Geranium pratense var. flore pleno; 8, a form of Geranium sanguineum; 9, Chelone obliqua.—*D. M.* Saponaria officinalis.—*G. M.* Silene compacta. — *E. J. B.* 1, Pterostyrax hispida (syn. Halesia hispida); 2, Syringa Emodii; 3, Celtis australis; 4, Stachys lanata; 5, Physostegia virginiana.—*A. C.* Emilia flammea.—*R. M.* Nicotiana rustica variety.— *G. S.* 1, A Veronica, impossible to name without flowers; 2, Achillea Millefolium; 3, Stachys lanata; 4, Coronilla Emerus (the Scorpion Senna).—*M. A. C.* 1, Inula Helenium; 2, Salvia glutinosa; 3, Tanacetum boreale; 4, Chrysanthemum macrophyllum; 5, Atropa Belladonna; 6, Lysimachia vulgare; 7, Borago officinalis; 8, Campanula Grossekii; 9, Geranium sylvaticum; 10, Pyrethrum Parthenium var. plenum; 11, Brickellia grandiflora; 12, specimen missing; 13, Carex pendula; 14, Polygonum cuspidatum; 15, Polygonum paniculatum; 16, Lathyrus niger.—*H. M.* Bougainvillea glabra; 2, Hoya carnosa; 3, Celosia plumosa; 4. Tecoma radicans; 5, Plumbago; 6, Nerium Oleander; 7, Coleus, variety not recognised. — *L. C.* 1, Galium verum; 2, Phyteuma orbiculare.—*C. M.* Catalpa bignonioides.—*P. C.* 1, Echinops Ritro; 2, probably Echinops viscosus; 3, Eryngium dichotomum; 4, Hypericum Hookerianum; 5, Spiraea Bumalda variety; 6, Olearia Haastii; 7, Spiraea Bumalda var. alba; 8, Solidago missouriensis; 9, Ceanothus azureus. — *E. H. T.* A Campanula of hybrid origin, not recognised.—*F. W.* Catalpa bignonioides. *A. H.* Insufficient material sent. —*J. M.* 1, Probably Spiraea canescens; 2, Cotoneaster frigida; 3, Rhus Cotinus.—*F. D.* (a) and (b) not recognised, send when in flower; (c) Tradescantia virginiana; (d) Ruscus aculeatus.— *G. S.* 1, Veronica Teucrium; 2, Stachys lanata; 3, Achillea Millefolium var. roseum; 4, Allium Moly; 5, Coronilla Emerus.— *T. R.* 1, Campanula garganica; 2, Campanula pusilla var. alba; 3, Veronica. not recognised.— *B. H. C.* 1, Begonia Luzerna; 2, Fuchsia corymbiflora; 3, Rondeletia odorata; 4, Dicksonia fibrosa; 5, Cyperus adenophorus; 6, Helenium autumnale var. striatum.— *C. H. W.* 1, Lilium sulphur-gale, a garden hybrid; 2, L. Wardii.—*C. D.* Helianthus mollis; North America, 1805.—*N. M. C.* Physostegia virginiana.—*J. M.* Lilium Henryi.—*P. G.* Nymphaea Marliacea var. alba.—*F. W. W.* 1 Pinus excelsa; 2, Pyrus Torminalis; 3, Pyrus Aucuparia; 4, Crataegus orientalis; 5, Juniperus virginiana; 6, Tilia petiolaris.—*J. F.* Probably Spiraea discolor, please send when in flower.

Plums Deformed.—*G. M.* The injuries to your Plums were probably caused at an early stage by cold winds, or by aphis.

Peaches Decaying.—*C. M.* The Barrington Peaches sent had split stones which was the cause of the fruits going bad around them. This variety is rather subject to stone-splitting and although very hardy, it requires good cultivation to bring out its best qualities. Remove the surface soil down to the roots during the winter months and top-dress with good loam and a liberal supply of old mortar-rubble or broken chalk, with a good sprinkling of bone-meal; this, with more liberal treatment during the growing season, should prevent stone-splitting in the future.

MARKETS.

COVENT GARDEN, Tuesday, September 24, 1929.

WE cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—The market is handling very considerable quantities at the moment and from a business point of view conditions are fair, although in some sections lower values are reported. Hothouse fruits, such as Grapes, Peaches, Nectarines and Melons, are maintaining steady prices, although the supplies of Grapes from Holland and Belgium, and Peaches from Italy, are offering strong competition. In the English Apple market there is some congestion of second grade fruits, and although there is also a large quantity of first-grade Apples available, they are meeting a fairly good demand from buyers. Plums are in heavy supply, but values in this section are strong and all varieties are doing well from a price point of view. The Tomato trade is not good, a few high grade fruits sell well, but others feel the heavy supplies of Jersey Tomatos that are reaching this market. Cucumber business is brisker than it has been for some time and values have improved. Mushrooms are more plentiful and quoted easier. A few hothouse Beans from Guernsey are selling well. Salads are a good market. The root crop trade is slow, and the demand in the Potato market shows improvement.

GLASGOW.

There was no particular feature in the business transacted in the cut flower market during the past week, and prices remained steady. Spray Chrysanthemums sold for 2s. 6d. to 8s. per dozen bunches; disbudded, white blooms, 10d. to 1s. 6d. for 6's; bronze and pink, 8d. to 1s. 3d.; and yellow, 9d. to 1s. 6d. Roses, all varieties, were worth from 2s. to 3s. per doz.; Carnations, 1s. 3d. to 2s.; specials, 2s. to 3s.; Gladioli, 2s. to 3s. per dozen bunches of 3's; Lilium speciosum rubrum, 3s. 6d. per bunch; Richardias, 3s. 6d. to 4s. 6d.; Dahlias, 2d. to 5d.; Sweet Peas, 2d. to 4d.; Asters, 2d. to 3d.; Physalis, 1s. 6d. to 2s.; white Heather, 7d. to 9d.; Asparagus, short, 5d. to 8d. bunch; medium, 9d. to 1s. 6d.; trails, 1s. to 2s. 6d.

In the fruit market large daily supplies of Plums made remunerative prices. Victorias ranged from 6d. to 9d. per lb. for table qualities, and 2½d. for seconds; Monarch, 4d. to 7d.; and 2d. for seconds; Damsons, 4d. to 6d. Hothouse Grapes made 3s. 6d. per lb. for black and 4s. for Muscats; Peaches, 6s. to 12s. per dozen; Pineapples, 4s. 6d. to 5s. 3d. each; Melons, 2s. 6d. to 3s.; Hazel Pears, 2d. to 4d. per lb.; Williams's bon Chrêtien, 10s. per sieve (24 lbs.); cooking Apples, 7s. to 8s. 6d. (56 lbs.) for first quality, and 4s. to 5s. seconds; Blackberries, 5d. to 6d. per lb.

Tomatos were dearer at 5s. 6d. to 7s. per 12 lb. chip; Cucumbers, 5s. to 6s. per dozen; Cauliflowers, 2s. to 4s.; Lettuces, 2s. 6d. to 2s. 9d. per box of 15 and 18; Brussels Sprouts, 2s. 6d. per sieve; Parsley, 2s. (8 lbs.); and Mushrooms, 2s. 6d. to 3s. per lb.

TRADE NOTES.

MESSRS. R. WALLACE AND CO., The Old Gardens, Tunbridge Wells, the well-known nurserymen, will hold their Annual Sale of high-class nursery stock on Wednesday and Thursday, October 9 and 10. This event is growing yearly in importance, and the catalogue this year contains a greater variety of subjects than have previously been offered, including many new and rare Rhododendrons, Japanese Cherries, Conifers, Lilies, choice herbaceous and alpine plants, bulbs, etc., also a grand selection of Messrs. Wallace's famous Irises. The nurseries are situated just off the Frant Road to the south of Tunbridge Wells, and are well worth a visit, especially at the time of the sale, when many of the shrubs should be showing beautiful autumn tints. The sale is conducted by the well-known Auctioneers, Messrs. Protheroe and Morris, of 67-68, Cheapside, E.C., who will be pleased to send a catalogue, which may also be obtained at The Old Gardens, Tunbridge Wells.

PATENTS AND TRADE MARKS.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle.*

WEATHER IN AUGUST.

THIS was the first month since November, 1928, to yield any excess of rainfall. For the rest, it was chiefly characterised by sea- and warm-direction winds, gradually "backing," on the whole, from N.W., through W. and S.W. to S. Temperature was extremely equable, except during the concluding half-dozen days, which were materially warmer—although no maxima above 73° were experienced. The month's mean temperature was 59·3°, or a trifle of 0·2° above the average. There were 165 hours of bright sunshine, or eleven fewer than the normal number. Rain fell on twenty-one days, or four more than the average; and the amount was 4·03 inches, which implies a small surplus of 0·36 inch. The subsoil water, however, was at an exceptionally low level. Thunder was reported, on three occasions, but all were only moderate to slight manifestations. As in July, visibility, on numerous days, was extremely good. Ozone was more abundant than usual. Gales were absent. *Joseph Baxendell, The Fernley Observatory, Southport.*

SCHEDULES RECEIVED.

KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.—Twenty-second Annual Exhibition, in the Assembly Rooms, Surbiton, on Wednesday, November 6, 1929.—Secretary, Mr. W. H. Divers, V.M.H., Westdean, Hook, Surbiton.

THE ROYAL HORTICULTURAL SOCIETY.—Fruit and Vegetable Show, to be held in the R.H.S. Halls, Greycoat Street and Vincent Square, S.W.1, on Tuesday and Wednesday, October 8 and 9, 1929.—Nut Competitions, to be held in the R.H.S. Hall, Vincent Square, S.W.1., on Tuesday, November 19, 1929. — Secretary, Royal Horticultural Society, Vincent Square, S.W.1.

GARDENING APPOINTMENT.

Mr. R. H. M. Ralph, for the past two years inside foreman at Cowdray Park, Midhurst, Sussex, as gardener to Major SCOTT, Willcamstrip Park, Coln St. Aldwyn, Cirencester, Gloucestershire. [Thanks for 2/- for R.G.O.F. Box.—EDS.]

Average Mean Temperature for the ensuing week, deduced from observations during the last fifty years at Greenwich, 51·8°.

Actual Temperature—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, October 2, 10 a.m. (Greenwich time). Bar. 29·7. Temp. 58°. Weather, Showery.

Harvest Time.

The "rolling seasons" have brought us to harvest time once again, but, following an exceptionally hot and dry period, not "everything rejoices." The hay harvest is a small one this year, and although straw is short, the crops of Cereals have been quite good, and only the slothful husbandman has failed to harvest them in first-rate condition. The seed-grower, too, has much cause for gratitude, and some for disappointment. There must first be free growth before the flowers can be produced abundantly, but if growth and blossom are ample, then fine weather is the only other condition necessary for securing a good harvest of seeds. Climatic conditions have not been entirely favourable to good growth, for the year has given us intense cold, brilliant sunshine followed by cold nights, a low rainfall and then a long period of brilliant sunshine and high temperature with practically no rain. Notwithstanding all these difficulties, however, garden crops have been wonderfully good, particularly in deeply worked soil. Growth may not have reached that luxuriance commonly experienced when an average rainfall accompanies high temperature, nevertheless few gardeners have grave cause for complaint in this respect, although annual flowers and some vegetables have had a shorter spell of usefulness than usual. However, there are garden seeds in abundance this time, and those enthusiasts who maintain their own strains, or have varieties of their own raising, cannot fail to be grateful for a good harvest and good harvest weather. The fruit harvest of the year may be considered good, for although there appears to be a shortage of Apples, most other fruits, and particularly small fruits, have yielded abundantly, and seldom have Peaches and Nectarines ripened so well out-of-doors as in this year of abnormally dry and brilliant weather. The nurseryman who deals in trees and shrubs is, perhaps, in the worst case among horticulturists, for even although his stock of these increasingly popular subjects may not have suffered greatly, he is at present very anxious about the weather, as, indeed, are all those who have much planting in view. A heavy rainfall is needed over a very large area of the country before it will be possible safely to lift and safely to plant Roses, fruit trees and ornamental trees and shrubs. But even the nurseryman may find some cause for thankfulness, as surface cultivation and dry weather have prevented the growth of weeds, while sunshine has "ripened up the wood." But gratitude for the harvest is not the prerogative of farmers, gardeners, nurserymen and seedsmen, therefore in countless places of worship the festival of harvest is now kept as regularly as it was by Jewish congregations in days of yore. Indeed, it would seem to have been a very general practice throughout the ages to render thanks for Nature's bounty. But what of the worker? How many hundreds of thousands who sing with great heartiness "We plough the fields and scatter the good seed on the land" have ever ploughed a furrow, dug a rod of ground, or sown a seed? Our complex civilisation notwithstanding, "all flesh is grass" continues and will ever continue to be a true saying. We are all dependent upon Mother Earth for her bounty, but the great majority of people have little thought for the sons of the soil—those honest, sturdy folk, who by the sweat of their brows compel the earth to yield her increase. The ploughman and the gardener, essential though they be to our well-being, receive scant thanks for their skilled labour, often receive wages that would in many instances be rejected by the dustman and the road sweeper, and, alas, they are too often regarded—by people of small understanding—as occupying a very low place in society. Gratitude is a poor thing to live on; gratitude that is expressed in terms of decent wages and comfortable homes is the practical kind that encourages those upon whose skill and labour we depend for our harvest.

Our Coloured Supplement Plate.—We have pleasure in presenting as a Supplement Plate to this issue an illustration of the richly-coloured Rhododendron King George, of continental origin and introduced into commerce by Messrs. van Nes and Sons, of Boskoop. This variety was raised in the gardens of the Royal Porcelain Factory, Berlin, where a series of crosses was carried out between R. Aucklandii and some of the older garden hybrids, the resulting seedlings, including R. King George, being purchased by Mr. van Nes. Another beautiful Rhododendron from the same source is the variety Queen Wilhelmina. R. King George has lovely Gloxinia-shaped flowers of brilliant scarlet colouring, produced in compact trusses, and is one of the most attractive of the hybrid Rhododendrons of continental origin. Unfortunately, it may only be regarded as hardy in the more favoured parts of this country, and requires shelter in the colder localities.

Holly Trees, Colchester.—Thursday, September 26, was an important day for Colchester when, in ideal weather, the High Steward of the Borough, the Right Hon. Annie Viscountess Cowdray, opened the Holly Trees mansion and grounds to the public. The grounds of this splendid old mansion (which is now to be used as a museum) adjoin the Castle Park and add twenty-seven acres of beautiful grounds to the open spaces. These have been tastefully laid out to the designs of a well-known local architect, Mr. Duncan Clark, and the planting is to be entrusted to two local firms, Messrs. E. Abbott and Sons and Messrs. Alfred Bunting, together with Messrs. R. W. Wallace and Co., Ltd., of Tunbridge Wells and Mr. Alfred Dawkins, of Chelsea. Alderman A. Owen Ward, in proposing a vote of thanks to the High Steward, expressed the deep gratitude of the citizens of Colchester that she, together with the late Viscount Cowdray, had made it possible for Colchester to possess this added attraction.

List of Fellows of the R.H.S.—The Royal Horticultural Society has just published a list of its Fellows, Associates and Affiliated Societies up to May 31, 1929, and it is stated that the names and addresses of Fellows and Associates elected, and Societies affiliated after that date, will be recorded in a supplement to be issued in the Book of Arrangements for 1930. This publication, which will prove useful to many for reference purposes, may be obtained upon application to the Society's offices, Vincent Square, Westminster, S.W.1, the price being 2s. 6d. to Fellows and 5s. to non-Fellows.

Acquirement of Open Spaces for the Public.—The Metropolitan Public Gardens Association has several schemes in hand for the acquirement of various areas of land for the use of the public. It is seeking to secure the Lessness Abbey Farm estate, and towards the purchase price of this estate, which embraces 215 acres, the sum of £5,000 has already been promised by local authorities. It is stated that another proposal under consideration is that of the purchase of Little Head Woods, fifty-two acres in extent, near Purley, the price of which is £5,700, towards which £1,200 has been obtained from voluntary sources. A good deal of money has been promised towards the £515,000 necessary for the purchase by the Association of nine acres of the Foundling Hospital in Bloomsbury, and the Association hopes that it will be possible to induce the local authorities to assist in the acquisition of this area. Smaller schemes of acquisition which the Association has under consideration include: Four acres, Wesley Avenue, Acton; Westcroft Square, Hammersmith; a quarter-of-an-acre adjoining an existing recreation ground in Whitgift Street, Lambeth; eleven acres at Pridmore Green, near Purley; and Tredegar Square, Bow Road, E.

The Japanese Beetle in the United States.—It often happens that a plant, animal or insect, which in its native country is of no importance, when introduced to another country becomes there a serious pest, the reason being that conditions in the new country—absence of its natural enemies chiefly—are favourable to its rapid increase. Such an instance is the introduction of the Japanese Beetle to America. An account of its activities, with records of control measures adopted, is set forth by Mr. Loren B. Smith, of the Bureau of Entomology, U.S. Department of Agriculture, in the *Year Book* of The Academy of Natural Sciences of Philadelphia (December 31, 1928). The Japanese Beetle was first discovered in America in 1916, at Riverton, New Jersey, when the only literature available dealing with this insect (Popillia japonica) stated that it occurred generally throughout the Islands of Japan, but was not a serious pest. In America, however, it increased in economic importance so rapidly that in 1917 it was deemed advisable by Federal and State authorities to undertake co-operative action for its extermination, and in the summer of 1918 work in this direction was commenced, but although large sums of money were spent in trying to check the spread of the pest—the infected area was isolated by maintaining a coat of poison on all foliage on a strip of land approximately half-a-mile wide all round the area—it soon became apparent that all efforts in this direction were a failure, although continued unceasingly throughout 1919 and 1920.

One reason for this is that the beetle is a vigorous flier and can cover several miles in a single flight, while vehicles passing through the area also assisted in its distribution. Over two-hundred and-fifty species of plants are reported as host plants to the beetle, which is most destructive in the adult stage, although the larvae (like that of the common May Bug or Cockchafer in this country), may do considerable damage to the roots of grasses, and among the plants liable to attack almost all the economic crops are included. Among the twenty-five or thirty plants specially preferred by the Japanese Beetle are Apple, Peach, Quince, Cherry, Plum, Grape, Soy Bean and Corn, together with several important shade trees. It attacks foliage, flowers and fruits, the foliage showing evidence of attack most conspicuously and partial or practically complete defoliation often resulting, as the attack on a tree is usually carried out *en masse*. With fruits, it is the early ripening ones that suffer most; for instance, on certain Peach trees of the variety Rochester, Japanese Beetles were responsible for the spoliation of eighty-seven per cent. of the fruits. As a primary measure of control, quarantine measures were inaugurated in 1918 by the New Jersey Department of Agriculture, and later by other State authorities; during 1928, the movement of practically all farm products, and of all nursery stock, sand, soil, peat, compost and manure, from the affected areas, was forbidden, and it is stated that these drastic measures have been definitely successful in checking the spread of the pest. Quarantine on all nursery stock and soil is effective in all Japanese Beetle areas. All produce which it is desired to move out of infested areas has to be certified as clean, while "balled" nursery stock is treated with dilute emulsified carbon-bisulphide. Various methods for the control of this pest have been developed and are proving of value. Trapping of the insects, it is stated, is now practised generally, and by this means a certain measure of control is obtained. For non-fruiting and ornamental subjects, spraying with a composition of lead arsenate paste and lead oliate, the latter serving as an excellent sticker and spreader, has proved efficacious, while a composition now on the market and stated to be in general use as a contact spray consists of Coco-nut fatty acid soap with a small amount of oleo-resin of Pyrethrum and sodium silicate added. To secure a higher kill with arsenate washes, attrahents in the form of essential oils of the plants most favoured by the beetle, were added to the sprays; Geraniol was found to be the most active in attracting the beetles, and its use in this respect has proved successful. Soil sterilisation and fumigation are employed to kill the larvae. Five species of parasites have been introduced from the Orient and liberated in the infested zone, and at present two entomologists are stationed in Japan and Korea to capture and breed these parasites. One of these, a Tachinid Fly, attacks the adult beetle, while the other four—two Dixiids and two Solitary Wasps—parasitize the larvae. Mr. Smith's account is supplemented with several extremely good illustrations, one of which shows a host of beetles attacking an Apple on the portion not covered by the arsenical spray, and another, Birch trees completely defoliated by Japanese Beetles.

Holland County Potato Show.—The ninth Holland County Potato Show, of which the schedule has just been issued, will be held at Spalding on Thursday, October 24. Thirteen Cups are offered for competition, ranging in value from ten to thirty-five guineas. For the best bag of English-grown ware Potatos in the show, a Challenge Cup (value £21) is offered by the London, Fruit, Flower and Vegetable Markets' Association, Ltd., and for the exhibitor gaining the highest number of points for prizes won in the ware classes a Challenge Cup (value £21) is offered by the National Federation of Fruit and Potato Trades' Associations. Challenge Cups are also offered for ware Potatos (open to growers in Great Britain), and also for collections of Potatos. A Trophy is offered for competition by the South Lincolnshire Wholesale Potato Merchants' Association for the best trade exhibit of Potatos.

Mr. Edward Winsor.—Bryanston, Blandford, Dorsetshire, the residence of Lord Portman, was the scene of the commencement of Mr. E. Winsor's very successful horticultural career. At Bryanston Gardens he served under Mr. Leach, and later under Mr. A. J. Allsop, and at the end of six-and-a-half years he removed to Penrhyn Castle Gardens to serve for three years under Mr. Walter Speed. From Penrhyn, Mr. Winsor went to Sandringham Gardens to take charge of the Carnation houses and also be responsible for the decoration of York Cottage. He stayed at Sandringham for three years, and then took the post of general foreman, under Mr. Walter Barnes, at Bear Wood Gardens, and while he was there the produce from these gardens, especially fruits and Chrysanthemums, secured many trophies and prizes at the leading horticultural shows. In August, 1906, Mr. Winsor left Bear Wood Gardens to take up the post of head gardener to Mr. Martin John Sutton, at Holme Park, Sonning-on-Thames, but in 1908 he took service with Morland Agnew, Esq., Croxley Green, Hertfordshire. In 1915 Mr. Winsor took over the management of Roundhay Park, Leeds, and so entered the second phase of his career—that of public service. In 1918, he succeeded Mr. Allsop as Superintendent of Leeds City Parks, and so well did he manage the parks under his control that in 1921, when the Blackburn Corporation was contemplating the extension and alteration, on a large scale, of the parks and public gardens of Blackburn, Mr. Winsor was offered the charge of this work which, as Parks Superintendent, he is still ably carrying on. When the extremely unfavourable conditions under which Mr. Winsor has had to labour in this big industrial town are borne in mind, nothing but unstinted praise is due to him for the success which has crowned his labours. A brief description of the parks under Mr. Winsor's supervision appeared in our issue of last week, p. 254, being an account of a recent visit to Blackburn of the North-western Branch of the Parks and Botanic Garden Superintendents' Association, while the illustration of Roe Lee Park (Fig. 125), showing the many mill chimneys in close proximity to it, gives some idea of the difficulties with which Mr. Winsor has to contend and also of the manner in which he surmounts them.

MR. EDWARD WINSOR.

The Drought.—With the arrival of rain, the second drought of an exceptionally dry year has been terminated, and many gardeners, and nurserymen especially, will be rejoicing. In the London area no recordable amount of rain fell for a period of thirty-six days, and it is the longest drought recorded in London since the British Rainfall Organisation commenced to make observations in 1858. Previous to last Sunday, the last rainfall recorded in the London area was the limited amount of 0·6 millimetre, between 7 p.m. on August 22 and 10 a.m. on August 23. In the Thames Valley the rainfall for the year, so far, has only been about half the average. In a statement on the dry weather of 1929, the Air Ministry records that for the eight months January to August, 1929, small patches with half the average rainfall are found in Nottinghamshire, east Lincolnshire, on the borders of Berkshire and Hampshire, and in east Kent. An area with less that sixty per cent. runs as a belt across England and Wales, the belt broadening considerably in the centre, and embracing the whole, or the greater part of, the counties of Radnor, Hereford, Worcester, Gloucester, Oxford, Buckingham, Berkshire, Wiltshire, east Somerset, Hampshire, Surrey and Kent. It is too early as yet to compare the dry weather of the present year with that of 1921—when for the nine months February to October less than fifty per cent. of the average rainfall was recorded over south-east England and a considerable part of the southern midlands—as September is not included in the above records and later months may have to be reckoned with before a final pronouncement is made.

Cheshire County Orchard Competition—In order to encourage the improvement of neglected orchards in the county of Cheshire and to promote the further planting of orchards, the Cheshire Branch of the National Farmers' Union Fruit and Vegetable Committee, together with the Agricultural Education Committee of the Cheshire County Council, promoted the first Cheshire County Orchard Competition. Twenty-two farmers entered their orchards, the majority of them being in the cultivated arable land section. The two sections for the competition were: (1) Cultivated grassland orchard of half-an-acre or over; (2) cultivated arable orchard of half-an-acre or over. In the first section, Miss M. Bostock, Merefield, Haslington, won first prize, with seventy-five points; Mr. J. Kitchen, Spring Bank Farm, Winsford, second, with sixty-seven points; and Mr. P. E. Meeres, Stock Lane, Wybunbury, third, with forty-three points; while in Section 2, the winning orchard was that of Mr. H. C. Groome, Guilden Sutton, near Chester, awarded eighty-eight points; second, Mr. A. C. Greg, M.A., Ash House, Acton Bridge, with eighty-six points; and third, Mr. William Bibby, London Road, Frodsham, with eighty-two points. The Greg Silver Cup, for the best orchard in the county of Cheshire, was awarded to Mr. H. C. Groome, Fruit Farms, Guilden Sutton, Chester. Great praise is due to Mr. W. E. Shewell-Cooper, the Cheshire County Horticultural Superintendent, for the manner in which the competition was organised, and for the general improvements in fruit growing in the county as a result of his efforts.

Irish Gardeners' Association's Excursion.—On Wednesday, September 21, the Daisy Hill Nursery, Newry, was the venue of the annual outing of the Irish Gardeners' Association, and about forty members availed themselves of the hospitality of Messrs. Smith and Locke. Upon arrival, the party was conducted over the extensive nurseries, the inspection taking up the greater part of the day, with a break for luncheon kindly provided by the proprietors.

A National Park.—The Prime Minister has appointed a Committee to enquire into the subject of establishing a National Park, or National Parks, in Great Britain. The terms of reference are:—"To consider and report if it is desirable and feasible to establish one or more national parks in Great Britain, with a view to the preservation of natural characteristics, including flora and fauna, and to the improvement of recreational facilities for the people; and to advise generally, and, in particular, as to the areas, if any, that are most suitable for the purpose." The Committee is composed of the Rt. Hon. Christopher Addison, M.P., M.D. (Chairman), Mr. H. L. French (Ministry of

Agriculture and Fisheries); Mr. A. S. Gaye (Commissioner of Crown Lands); Mr. I. G. Gibbon (Ministry of Health); Sir Robert Greig, M.C. (Secretary to the Department of Agriculture for Scotland); Sir E. W. E. Holderness, Bart. (Home Office); Mr. F. J. E. Raby, F.S.A. (Office of Works); and Sir John Stirling-Maxwell, Bart., K.T. (Forestry Commissioner).

Survey of Soils and Fruits in the Wisbech Area.—The Ministry of Agriculture and Fisheries has recently published a monograph consisting of an account of the work and results obtained in the survey of the soils and fruits of the Wisbech Area, by C. Wright, M.A., N.D.H., and J. F. Ward, M.A. (Research Monograph No. 6; price 3s. 6d.). The Ministry hopes to publish, as they are completed, a series of similar surveys of the various fruit areas of this country, and the present volume is the first of the series. Three surveys have so far been completed—two in the East Anglian area and one in the west Midland area—and other surveys are in progress. The survey work is being supervised by the special Fruit Soils Survey Committee of the Advisory Chemists Conference. The present Monograph is divided into three parts:—Part I, Soils; Part II, Fruit; and Part III, The Relation Between Soil and Fruit; each subject being dealt with in every aspect. Appended are various tables of soil analyses; effects of soil on the size of Apple and Plum trees, stoutness of extension growth, and size of fruits, also on susceptibility of Apples and Plums, respectively, to Silver Leaf. Three maps are issued with the Monograph, and these show (1) the soil types; (2) the distribution of fruit trees in 1924; and (3) the distribution of Strawberries, in the Wisbech area.

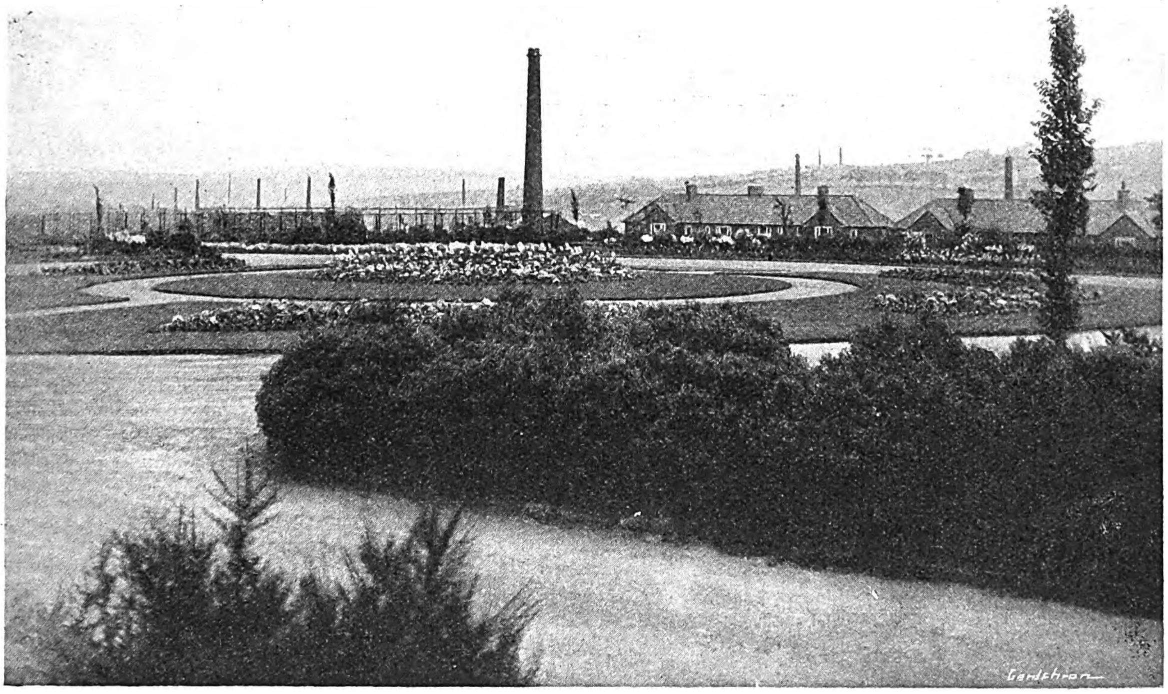

FIG. 125.—A VIEW IN ROE LEE PARK, BLACKBURN.

National Sweet Pea Society's Annual Meeting.—Unusual interest attaches to the Annual General Meeting of members of the National Sweet Pea Society, on Wednesday, October 16, as it will be the first one not held in London proper, although within the Metropolitan postal district. The meeting will commence at 3 p.m., and will be held in the dining room of Messrs. James Carter and Co.'s establishment at Raynes Park, London, S.W.20. In the same hall, the President, Mr. Harold Beale, will entertain the members to lunch at 12.30 p.m., and while the dining room is being made ready for the Annual Meeting, members will have an opportunity of inspecting the seed warehouses, offices and nursery. A proposed alteration of Rules will be considered by the members; if adopted it will mean that the Society's Gold Medal need not necessarily be awarded to the Sweet Pea which the Floral Committee considers the best at the Trials each year and, further, that if a Gold Medal is awarded, it shall not be provisional and dependent upon the conduct of the variety at the Trials in the following season. Yet another proposal aims at reducing the penalty imposed in respect of purity or trueness in varieties on Trial; the Rule reads "No Award of any kind shall be made to a variety that, at the Trials, contains a rogue or rogues." If the proposed alteration is adopted the reading will be "No Award of any kind will be made to a variety that, at the Trials, contains more than one plant rogue." Remembering the discussions that have taken place over the question of purity of novelties at the N.S.P.S. Trials, we do not anticipate an easy passage for the last-named proposal.

Ceanothus Burkwoodii.—Referring to the "very accurate account of our novelty, Ceanothus Burkwoodii, in *The Gardeners' Chronicle* of September 21," Messrs. Burkwood and Skipworth, Ltd., state that they have no desire to conceal the origin of this plant. It was raised by crossing the spring-flowering C. floribundus—from which it has derived the evergreen character—with C. Indigo.

Appointments for the Ensuing Week.—Monday, October 7: Derbyshire Horticultural Association's meeting; National Chrysanthemum Society's Floral Committee; Birmingham and Midland Counties Gardeners' Association's lecture. Tuesday, October 8: Royal Horticultural Society's Autumn Show (two days); Jersey Gardeners' Society's meeting. Wednesday, October 9: Wimbledon Gardeners' Society's meeting; Sheffield Chrysanthemum Society's lecture. Friday, October 11: Royal Horticultural and Arboricultural Society of Ireland's meeting. Saturday, October 12: Faversham Chrysanthemum Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Profits of Pear Growing.*—An observation of M. de Jonghe, in one of your late numbers, to the effect that England, from mismanagement, is tributary to Belgium for Pears, induces me to remark the high price at which this fruit is retailed in Covent Garden. I have seldom been able to purchase first-rate winter fruit, such as Winter Nelis, Beurré Rance, Easter Beurré, or Ne plus Meuris, under 6d. apiece, and never under 4d. Now let us suppose an acre stocked with pyramidal trees, at six feet apart, there is room for 1,210. In good condition, they surely ought to produce two dozen Pears each; but let us suppose that every other tree is absolutely barren every alternate year; the average will then be a dozen fruit per tree. Let us now assume that even of this dozen one-half is cracked, pecked, rotten, or otherwise unsaleable; there will remain half-a-dozen in good condition. Let us halve these again, and suppose that only three can be retailed at the full price of 6d., and that the other three will only produce 4d. each. We have thus 2s. 6d. per tree, or £152 per acre. What the retailer's profit is, I know not, but assuming him to be contented with fifty-two per cent., he will pay the grower £100. Now £100 an acre seems an enormous return, even after allowing that the trees, at 1s. 6d. each, must originally have cost £90, and that annual expenses such as rent, taxes and labour, have to be deducted. Hence we may conclude, either that Pear-growers are driving a most lucrative trade, or else that amateurs must not, on an average of years, expect a return from the pyramidal trees of even six good fruit from each. The culture of standards is usually considered more profitable than pyramids. If so, market gardeners, who almost always plant standards, will actually realise larger profits than those I have indicated above. *S. B., Bromley. Gard. Chron., October 7,* 1854.

Publications Received. — *Taschenatlas der Krankheiten des Beeren und Schalenobstes*; Von Prof. Dr. Otto Appel. Berlin SW11, Verlag Paul Parey, Hedemannstr. 28/29. Price Rm. 6.00.—*Le Nouveau Jardiniste Moderne*; Par Prosper Péan; Paris, Librairie de la Construction Moderne, 13, Rue de l'Odéon.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Cycnoches, Catasetums, Mormodes, etc.—These warm-house, deciduous Orchids, many of which produce flowers on completion of the season's growth, have grown well during the summer months, and the brilliant sunshine enjoyed during September has assisted the completion of the new pseudo-bulbs on many of them. Those that are developing flower scapes should be given sufficient moisture at the roots to keep the flower buds growing until fully expanded. At this season, the plants should be grown in a light position, where they are exposed to all available sunshine, with a good circulation of fresh air, to assist the pseudo-bulbs to ripen, and as growth becomes complete and the leaves turn colour, water should be withheld gradually. When the leaves have fallen the plants should be allowed to rest in a light position near the glass, where the air can circulate around them, and an intermediate temperature maintained until signs of activity are noticed in the spring. During the resting period no water will be required, unless the leading pseudo-bulbs appear to be shrivelling, when one good application will generally suffice to plump up the pseudo-bulbs to a normal condition again. Much depends on the proper ripening of the pseudo-bulbs at this season if they are to pass successfully through the dull winter months, especially in smoky districts where the light is so deficient during winter fogs. The pseudo-bulbs should be examined carefully for the presence of small scale insects which, if found, should be removed with the aid of a small brush and a safe insecticide, care being taken to avoid any injury to the eyes or growing points.

Cypripediums.—Specimens of the autumn- and winter-flowering Cypripediums form a leading feature in many collections to-day, as they are comparatively easy to grow and give a return of flowers which keep in perfection for many weeks during the dull period of the year. The varieties are too numerous to enumerate, being sufficient in number to meet the most exacting tastes. The early-flowering sorts, embracing both species and hybrids, especially those derived from the dainty C. Fairrieanum, C. Charlesworthii, and others, are now producing flower buds. Root action is very active at this stage, and the plants should be given copious supplies of water at the roots each time the soil appears dry. Neglect of this point at this stage often results in deformed flowers and sickly-looking plants. The flower stems should be secured loosely to neat stakes, before the stems become twisted through being confined in the foliage. Later, as the blooms expand, the stems may be secured so as to show the flowers to the best advantage. Plenty of light should be allowed to reach the plants, with a reasonable amount of fresh air on all favourable occasions, in order to secure a good texture in the leaves and develop substance and colour in the blooms. Very little shade during the hottest part of the day will now be needed, and as the sunlight declines this should be dispensed with altogether until the early spring months. Thrips and other insect pests should be kept in check by an occasional fumigation on quiet evenings, and the foliage cleaned by sponging with soapy water to remove the dirt which enters owing to the extra ventilation, especially in smoky districts.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Storing Pears.—Pears are very much more difficult to manage in store than are Apples. They mature so suddenly, and at times so unexpectedly, that the fruit-grower has to be on the alert all the time. In the fruit room he may go through the lot one morning and find everything correct, while the next, or two days later, on entering the store he may be made suddenly aware of that most wonderful aroma—the aroma of a few ripening Pears ; so that they call for the very closest attention the whole season through. The late-keeping varieties, such as Olivier de Serres, Glou Morceau, Beurré Alexandre Lucas, Beurré Rance, Beurré Easter, and Joséphine de Malines, should be allowed to hang on the trees right up to the last week in October, if necessary, to prevent shrivelling in store so much as possible. Unlike Apples, they like warmer and drier conditions, with complete darkness. To allow for frequent inspection, they should be laid out in single layers. The shelves should first be covered with a thin layer of wood-wool to prevent bruising and to allow the air to circulate under and among the fruits. Where Apples and Pears must, of necessity, be stored in the same room, the upper shelves should be reserved for the dessert Pears, because the air there is generally drier and warmer ; the centre shelves for the mid-season Apples, while the lower shelves or floor space should prove most suitable for the late-maturing Apples and stewing Pears.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Chrysanthemums.—In view of the long period during which the Chrysanthemum is expected to provide flowers, the late varieties are best kept out-of-doors for some time to come, but as frosts may be expected after this date, it will be wise to make some provision for protection. A good plan is to have a skeleton frame prepared and fitted with blinds that may be drawn over the Chrysanthemums at night when frost is expected. Mildew is liable to attack Chrysanthemums at this season, and means should be taken to check this ; there are many good proprietary mixtures obtainable, and if used according to directions, this troublesome disease may be kept in check. Plants that have been grown to produce large blooms should have been housed by this date ; if mildew makes its appearance on these, it is best to dust the leaves with flowers of sulphur. During dull days a little fire-heat may be necessary to dispel dampness and keep the atmosphere buoyant, but never allow the roots to suffer through lack of water once the flowers are opening, otherwise damping-off of the petals may follow.

Begonia Gloire de Lorraine.—Plants of this Begonia should be kept growing in an intermediate temperature, but with less shade than was given during the summer months, and where possible, more room should be allowed them so that the plants may develop their flowers equally all round. Some of the earlier plants may now be allowed to flower, while others should have their flowers removed to enable them to provide a succession to those that flower from now onwards. The variety Mrs. Peterson is generally much later in forming a good plant, and by removing the flower buds that do appear, good flowering specimens may be secured for the early part of January next year. While these Begonias require some care when applying water to the roots, they should never be allowed to suffer through lack of moisture. Well-rooted specimens should be afforded applications of a light stimulant alternately with clear water ; weak soot-water tends to give the foliage a dark green appearance, and also assists the production of flowers of good quality. The plants should be neatly staked to prevent them from bending down with the weight of their flowers.

Cyclamens.—Where a large number of these are cultivated, some of the earlier plants may be placed in a lean-to house, for preference near the roof glass, and their flowers allowed to develop as they appear. A minimum temperature of 50° should be maintained. Plants that are now producing their flower stems require a little extra care when applying water to the roots, and at no time should moisture be allowed to lodge in the crown of the plant, otherwise the flower stalks may damp off. If the receptacles are well filled with roots, the plants should benefit by light applications of liquid manure, and if a concentrated fertiliser is used, care should be taken that it does not come into contact with the centre of the crown. Freedom from insect pests is most essential and as a preventive the plants should be fumigated with XL All insecticide on two or three occasions. This should free them from aphis and check the spread of mites should any be present.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Figs.—Fruits on Fig trees under glass should now be finished, and the trees in pots or borders resting. There is nothing gained by allowing second crops in late houses and third crops in early ones, to swell, as what they gain now they will lose later, for half-rested trees will commence casting their fruits when they should be swelling to maturity. If the autumn continues fine and dry, the pot trees may be kept near the foot of a wall until the house or pit is ready for them. As Figs are very subject to red spider, bug and scale, they should be washed carefully, and dressed with Gishurst compound, and the house well cleansed with hot water, quick-lime and sulphur before the trees are taken in again. Sudden and severe autumn frosts do them no good, therefore the houses should be got ready for their reception, and any fermenting material, consisting principally of Oak leaves and a small percentage of fresh stable litter, prepared in readiness for starting by the end of November or early December. Pot Figs, under good management, improve with age ; once started into growth, the balls of roots should never become dry until all the fruits are gathered. When this stage is reached and the pots are removed from the plunging material, all external roots may be cut off and the trees repotted, or large trees may be kept in pots of the same size for years, as the annual roots support the crop, always provided the roots never suffer through lack of water.

Cherries.—The past month has been rather too hot for trained trees under fixed roofs, especially if red spider injured the leaves early in the season. Too much late, direct syringing only aggravates the evil, as the moisture so provided only induces the leafless buds to swell. As much air as possible should be admitted, both night and day, and shading from bright sun may be resorted to, but the best of all supplementary checks will be found in shortening the strong roots. Where roof lights can be removed, the trees may be kept dormant by full exposure and night dew, while artificial watering or rain may keep the roots wet enough. Trees in pots now plunged outside will have had the benefit of cool nights and, provided the foliage is still hanging, the buds should now be safe. A mass of roots being essential to success, water should be given in sufficient quantity to prevent an unduly dry condition at the roots.

Plums.—The preceding remarks are also applicable to early and midseason Plums, which cannot be kept too cool. A good washing with the hose will keep any late attacks of green or black fly in check. The fruits on pot trees of Golden Drop, the king of dessert Plums, should now be in perfect condition, and are worthy of the greatest care ; protection from wasps and flies and a free circulation of dry air is imperative. This variety is not, as a rule very prolific, but makes up for that by carrying a fair crop every year. As the fruits improve in quality and value after they are ripe, the roots of the trees should be kept moderately moist and well covered to prevent drying out.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Paeonies.—Among herbaceous plants that may with advantage be planted during early October are the beautiful Paeonies, which rank among the best of our hardy plants, for they combine delightful form with lovely colours, and in some varieties the blooms are pleasantly fragrant. The season of flowering can be considerably prolonged by planting the early-flowering, European varieties, to be followed by the Chinese sorts later. In most gardens there is a partly shaded border in which Paeonies may be grown with advantage. In such a position they make luxuriant growth, and the colours of the flowers are better, besides lasting much longer, than when in an open, sunny position. They are such good plants that it is not advisable to mix them with other subjects in the ordinary herbaceous border, for they are worthy of a site apart, where they can remain undisturbed for several years. In such positions groups of Liliums planted here and there between the clumps will help to prolong the flowering season of the border and do no harm to the Paeonies. The edges of drives or paths in the pleasure grounds, where they may receive shade from the surrounding trees, also provide admirable sites for groups of these handsome plants. Yet another use can be made of them *i.e.*, for furnishing the wild garden, where, if planted judiciously, they will produce a telling effect. When preparing a position for these Paeonies, bear in mind that they ought to remain undisturbed for years if the best results are to be obtained. The soil for them should be deeply trenched—two-and-a-half feet is none too deep —and a plentiful supply of well-decayed cow manure incorporated as the work proceeds. See that the ground is sweet and well drained, for Paeonies relish a moist, rich soil, but resent anything in the way of stagnant moisture; also, be sure that the site is not subject to late spring frosts, which will damage the tender young growths and buds. Allow the ground to settle before planting. Place the clumps three feet apart each way, doing as little damage as possible to the fleshy roots. It is not to be expected that there will be much bloom the first year after planting, but if the work has been done carefully and good plants used, from the second year after transplanting a plentiful supply of good flowers will be the reward for a number of years. When the borders or groups are well established an annual top-dressing of well-decayed manure during the growing season should be beneficial; also waterings with weak liquid manure when the clumps are covered with their flower buds.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Cardoons.—These should now receive their final earthing-up. Build up plenty of soil around the plants, but before doing this clear away any small leaves at the base of the stems; tie them up with one or two strands of Raffia sufficiently loosely to allow for further swelling, as the plants fill out rapidly at this time of year.

Seakale.—Remove any decayed leaves from the plants. Stir the soil between the rows with the hoe, and keep the bed free from weeds.

Winter Salads.—Attend to the batches of Lettuces in frames; keep the soil well stirred, and give a light dusting of soot around the plants to keep slugs in check. Mustard and Cress should now be sown in boxes in a warm house; batches may be sown every ten days to maintain a continuous supply.

Jerusalem Artichokes.—These have grown to a fair height this season, and the growths may be cut back two feet or more to encourage the swelling of the tubers and prevent the growths being blown about by strong winds; it will also let more light and air reach the base of the plants.

Tomatos.—Shorten most of the leaves on these so as to allow the sun to ripen the fruits, and give an application of liquid manure to assist the fruits in swelling. Should frost occur, pull the plants up and hang them in a warm dry, airy house so that the remaining fruits may ripen.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Root-pruning.—No time is better suited for this work than the present, and in most gardens a few trees require to be taken in hand each year. Where growth is over-luxuriant and cropping poor, little good follows the annual removal of top growths, but a reduction of the rooting system soon puts matters right, and if done while the leaves are still on the trees, root action begins at once, instead of being deferred until spring. Young trees on reducing stocks, both Apples and Pears, and all stone fruits, should be root-pruned frequently until they settle down to bear regularly, and occasionally even after this. If half the roots are treated at a time, the remainder being left undisturbed until the following year, no serious check will result. All strong, gross roots should be cut back close to the ball, cutting them with a sharp knife on the upper side, so that the roots emitted have an upward tendency. A quantity of new soil, preferably virgin loam full of fibre, placed around the roots and made quite firm, should prove beneficial, but no manure of any kind should be mixed with it, although a mulch of partly decayed farmyard manure on the surface or just under it, will raise the temperature of the soil at the time, and so accelerate the production of new roots, and encourage the upward growth of the roots, which is most desirable. Old-established fruit trees of all kinds which have got out of condition can soon be restored to fruiting, if in a healthy state, by root-pruning, but if canker or gumming is in evidence, they are not worth the labour. Attack the roots in the first place, and afterwards the branches, removing a few each year until in time a practically new tree is produced. In the case of stone fruits, young wood gives the best and largest crops, but in the case of Apples and Pears the existing branches may be retained if desired, cutting away the old spurs gradually. Considerable care and judgment should be exercised in treating the roots of old trees; if thick and heavy; the severing of one at a time may be sufficient, and this should be done with a saw, smoothing the wound over with a sharp knife. Roots penetrating deeply into the ground should be dealt with first as they are most likely to be the miscreants.

Peaches.—So soon as the last fruits are gathered on outdoor trees, the old wood should be removed, leaving only sufficient to clothe the wall, so that no winter pruning will be necessary; extra light and air will also be admitted to the young growths on which next season's crop will be produced. If the soil around the trees is forked over and a good mulch of rich manure, or a watering with liquid manure, is given, it will do much to build up the buds before the leaves fall.

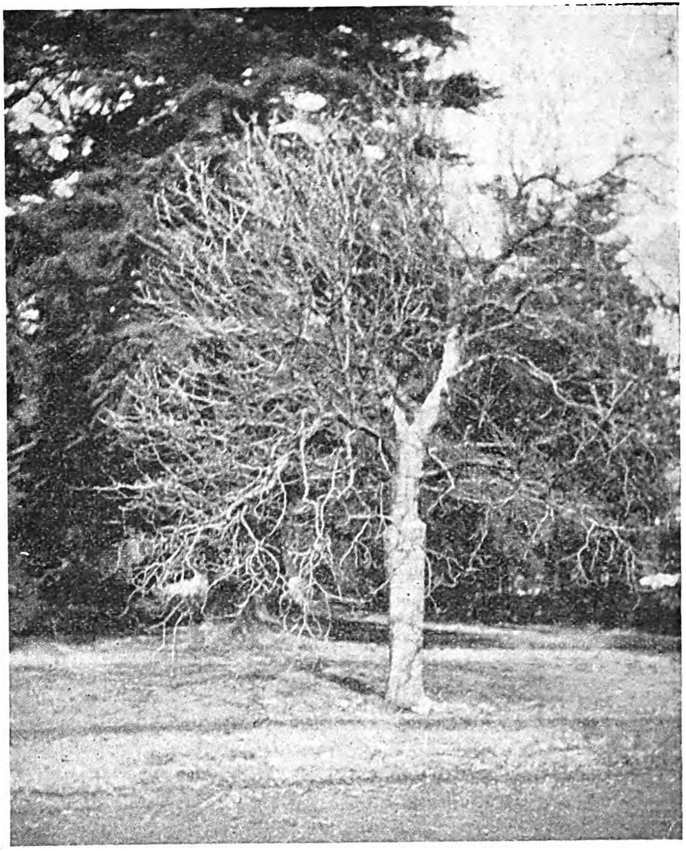

FIG. 126.—AESCULUS CALIFORNICA.
(see p. 263.)

Roses.—Where dwarf Roses, especially H.P.'s, have made strong, woody growths, these should be shortened almost to one half their length to prevent breakage by wind. If black spot or rust has been prevalent, the leaves should be carefully collected and burned at once to destroy the resting spores, after which the bushes should be sprayed with a good fungicide.

Brussels Sprouts.—The lower leaves, at least half way up, should be removed to allow a better circulation of air to develop the sprouts or they may be of poor quality and liable to decay in wet weather. In the case of Cabbages, Broccoli and Asparagus Kale, only decaying leaves should be removed to expose the stems as much as possible so that they may become firm in texture before frosts set in, or much damage may result from stem-splitting, especially among Broccoli.

INDOOR PLANTS.

DATURA SUAVEOLENS.

Datura suaveolens, often called Brugmansia suaveolens, belongs to the Natural Order Solanaceae, and was introduced from Mexico to this country in 1733.

The pure white blooms are trumpet shaped and often over five inches in diameter. They are seen to their greatest advantage at night, for they are then fully open, and the rich perfume permeates the atmosphere around, while during the day the blossoms are closed somewhat.

This gorgeous, freely-flowering Datura seems to bear its blooms in crops during August and September, the flowers remaining on the plant for practically a whole week before turning brown and falling off. The large, elliptical-oblong leaves are perfectly entire, the upper surface glabrous, the lower sparsely hairy.

When grown in a cool corridor or such like place, where it has plenty of "head room," it attains a height of ten to fifteen feet. Propagation may be effected by means of cuttings taken and rooted in sand during spring.

When the mature plants lose their leaves in autumn, water should be withheld from them to some extent, as the wood, being of a soft, fleshy nature, is very liable to decay. It appears to grow and flower more freely in a shady position than in one where it is subjected to the full rays of the sun. D. Knightii is a double-flowered variety of this species. *F. H. Wright, University Botanic Gardens, Cambridge.*

IMPATIENS SULTANI.

The Balsam family contains many excellent decorative plants, but none can surpass in elegance of habit, freedom of flowering and general usefulness this plant, named in honour of the Sultan of Zanzibar. It is stated to have originated as a chance seedling in the compost of an importation of other plants from Zanzibar in 1883.

The flowers of this charming plant can be enjoyed during the whole year with the aid of a cool greenhouse, while its value as a bedding plant during the summer months is well-known; its beautiful, bright rose flowers, so abundantly produced, create masses of delicate colour. It is particularly useful as a pot plant for room decoration, excellent for furnishing the conservatory at all times of the year, and makes a splendid hanging basket plant during the summer.

Impatiens Sultani is easily raised from seeds, while cuttings placed under a bell-glass strike very freely at almost any season; it grows vigorously in any sweet compost, and is relatively free from the attacks of pests and diseases. *W. A.*

XANTHOSOMA LINDENI.

Xanthosoma Lindeni, the most generally cultivated species of the genus, is an old garden plant, having been introduced from New Grenada some seven years later than Xanthosoma violaceum, which, after being cultivated in plant stoves for upwards of sixty-five years, received an Award of Merit at a recent meeting of the Royal Horticultural Society.

In common with many other tropical Aroids, the spathes of X. Lindeni are somewhat dingy and unattractive, but when well grown, its hastate leaves, one foot in length, held well aloft on strong, tapering petioles, with wide, silvery bands margining the median and branching veins running herring-bone fashion on the deep green upper surface, are distinctly ornamental.

Plants of a useful decorative size, from fifteen to eighteen inches high, may be grown in five-inch pots, and larger specimens of several plants, in correspondingly larger receptacles. In addition to the type, there is a variety similar in character but with much larger leaves, by name, X. L. var. magnificum. It is also known as Phyllotaenium Lindeni var. magnificum.

This Xanthosoma may be increased by division of the tuberous rhizomes in early spring, before active growth commences, when the plants should be overhauled, the drainage examined, dead roots removed, and sour soil replaced with fresh, sweet compost. The plants should be grown in a brisk, moist heat, to encourage a healthy and rapid growth. *Jonathan Fiona.*

ALPINE GARDEN.

SEDUM MONREGALENSE.

This is by no means a common Sedum in gardens or nurseries, but it is one whose merits thoroughly deserve a wider recognition, for it is not only reliable in the production of blooms and a bright and cheerful little plant, but it is one of the few Sedums which appreciate a cool and sunless situation.

S. monregalense is a lowly, creeping perennial species, the slender, decumbent stems rooting as growth proceeds. These stems are closely furnished with fleshy, blunt, oblanceolate leaves, usually in whorls of four, and of a pale yellowish-green. Rising to three or more inches above the mat of foliage, the flowering stems break into a panicled cyme and bear at their extremities comparatively large, pure-white, star-shaped blossoms. These blooms are not only produced in great abundance, but a succession is maintained throughout the later summer and often well into autumn. Although a native of the warmer parts of south-eastern Europe, S. monregalense is absolutely hardy. It appears to thrive in any average loam that is gritty and freely drained, but to do really well a damp spot with shelter from the hottest sun is desirable. *J.*

ANDROSACE LANUGINOSA.

It may appear almost superfluous to write about that lovely Androsace, A. lanuginosa, so well known is it to most growers of rock plants and so frequently seen in gardens. Yet one finds apparently that even really lovely old plants may be overlooked in purchasing additions to the garden, especially when we have so many new treasures at our doors clamouring for admission, whose claims are not to be ignored, and whose beauties are undeniable, although not always superior to those of our older plants. And among the numerous plants of grace or beauty the Androsaces are in the first rank and, although the assertion may be criticised, I do not think that any one of the species can cast A. lanuginosa in the shade, so lovely and so delightful is it. Farrer did not exceed the truth when he characterised A. lanuginosa in the *English Rock Garden* as "among our most precious and universal rock garden ornaments."

It is a joy to see its long, trailing shoots clad with their silvery, silken leaves and bedecked with their many Verbena-like heads of finest rose-lilac. The variety A. l. var. Leichtlinii has white flowers, with an eye of crimson or yellow, and is very beautiful also, although after the lapse of a few years after its introduction one came to the conclusion that the typical lilac-rose plant is the more beautiful of the two.

Happily, too, the culture of these gems is not beyond the skill of the many who own rock gardens. A sandy soil and a sunny situation answers well for A. lanuginosa, which is perfectly hardy. It also does well in a sunny moraine. In either the rock garden or the moraine it will bloom for months in succession and last in flower until after the early frosts have cut down many other flowers.

In very wet climates A. lanuginosa survives better if sheltered from winter rains by a sheet of glass, but this is not absolutely necessary. Propagation is effected by cuttings or seeds.

LINARIA ANTICARIA.

Upwards of five and twenty years ago, at a time when I was endeavouring to make myself acquainted with a number of little-known flowers, I purchased a packet of seeds of Linaria anticaria, sold as an "annual Toadflax," and recommended for the rock garden. It proved to be a pretty, although not showy, species, about three or four inches high, and I was intrigued into studying its variations, which were very considerable, especially in the ground colour, which was generally yellow, buff or greyish. The throats were brown, yellow, reddish and white, as a rule, but I took a note of the variations, which I believe I have somewhere among my horticultural notes. It will, I have no doubt, be thought that this was not worth while, but it was interesting to me at the time.

L. anticaria is best treated as an annual, but in the garden I then had, close to the sea, plants frequently survived the winter, while self-sown seedlings maintained the succession for some years. On leaving this garden, I took no plants of L. anticaria with me, and had not grown it for many years, until in 1928, a plant of L. anticaria made its appearance on a retaining wall along with other alpines. This flowered, and this summer several self-sown seedlings made their appearance, and will probably furnish me with plants in the future. I am writing this to bring L. anticaria to the notice of readers interested in rock plants, and who wish for a few annuals suitable for the rock garden, which would not be too aggressive and would come in well where early bulbs are grown.

L. anticaria is only about three or four inches high, has narrow leaves and small flowers of the ground colour indicated above and prettily marked on the lip. It is best treated as a hardy annual, and either sown where it is to bloom, above early bulbs, or allowed to seed itself among other plants. It is not a greedy plant in the way of soil, and is hardly capable of doing harm to its neighbours, however choice. *S. Arnott.*

FLOWER GARDEN.

COSMOS BIPINNATUS.

About the beginning of this century, many people had difficulty in getting this annual to flower in their gardens before it was cut down by frost. Gardeners who made experiments recommended it to be raised in heat, and transplanted twice, before being finally planted in the garden. The treatment was intended to check its vigour and induce early flowering. This is altogether unnecessary if seeds are sown in light or sandy soils. It is practically a weed in many gardens on sandy, alluvial soils of the Thames valley, west of London, and may be so elsewhere.

Although this Mexican plant is cut down by the first sharp frost, like Dahlias, it ripens and scatters seeds abundantly before the advent of frost. Seedlings spring up in the gardens, and appear in other gardens where none were planted, just as Impatiens Roylei does, although the means of transit must be different to some extent in the two cases. The walls of the fruit of Impatiens are elastic, and throw the seeds to a distance at maturity. The achenes or fruits of the above Cosmos are of two forms. The outer ones have a short neck furnished with hooks or stout, reversed hairs. The inner ones have long necks without hooks; sometimes these are fertile and sometimes they contain no seeds, as if the disc flowers had a tendency to become male only. Those with hooks are liable to be distributed by various small animals that frequent gardens. *J. F.*

NOLANA ATRIPLICIFOLIA VAR. GRANDIFLORA.

It seems very strange that this hardy annual is not very well known, as most people nowadays would welcome the tone of blue exhibited by this lovely plant, and the shade might be likened to that of the flowers of that favourite wall plant, Ceanothus Gloire de Versailles. Yet the blue is not the only colour which the Convolvulus-shaped flowers of this plant possess, as each bloom, when fully opened, shows a zone of lemon, white and blue, the lemon being lowermost, the white in the centre, and the blue uppermost. Several stems are produced by each plant, and on these are borne the successional flowers.

The blooms—which measure one-and-a-half inch in diameter—open and close daily, and each lasts in good condition for two days, afterwards the pedicels, which vary in length from one inch to two inches, bend downwards. The plaited corollas, too, are also interesting.

A sunny position should be chosen for N. a. var. grandiflora, and the seeds should be sown thinly in any good soil, in April or May, when the plants will flower in August. *D. A., Midlothian.*

TREES AND SHRUBS.

TWO INTERESTING TREES.

Having come across two very interesting trees in the grounds at the Manor House, Stanmore, where Mr. Samuel Wallrock has been so busy during the past three or four years planning and designing his charming gardens, which lie on the fringe of the ever-advancing Metropolis, I made notes of them. The two trees, an Ash and an Aesculus, caught my eye in a moment, when visiting the Manor House, in spring and recognising that they would probably interest tree lovers who con the pages of *The Gardeners' Chronicle*, I was fortunate in obtaining the photographs sent herewith.

The Ash, a variety of Fraxinus excelsior, is one of the most strikingly contorted trees that I have ever seen. These contortions are distinctly shown in the photograph (Fig. 127), and although many folk might probably regard it as monstrous, a second glance at the illustration will discover that the tree is quite handsome, pleasing, and of semi-pendulous habit.

Aesculus californica, the Californian Buckeye, belongs to the section of this genus at one time named Pavia; it is indigenous to the American continent, and the picture (Fig. 126) being taken when the tree was out of leaf, shows the junction where it was originally grafted, the stock having made greater growth than the scion, a happening that is too frequently reversed to the detriment of the latter. As an isolated specimen tree, of small dimensions, this is an admirable example, and I was told that it flowered and fruited freely last season. *E. Beckett.*

LONICERA MAACKII.

The shrubby Honeysuckles are somewhat overshadowed by their climbing congeners and are, perhaps, not so generally grown as they, for the most part, well deserve to be.

L. Maackii is a much-branched shrub, attaining a height of eight to ten feet, the spreading branches being well furnished with ovate, elliptic leaves, in the axils of which are clusters of white, trumpet-shaped flowers. Of rapid growth, this really fine Honeysuckle makes an attractive, bushy specimen, or may be grouped to advantage in the shrub border; its flowers are of appreciable size and sufficiently numerous to create a most attractive feature. L. Maackii was, I think, introduced by the late firm of Messrs. J. Veitch and Sons several years ago, when it received an Award of Merit from the R.H.S.

Other shrubby and deciduous Loniceras not often grown and yet of considerable merit are L. chrysantha, L. involucrata, L. Ledebourii, L. Ruprechtiana and L. Standishii. *Ralph E. Arnold.*

ERIOBOTRYA JAPONICA.

The Loquat, or Japanese Medlar, is a native of China and Japan, and belongs to the Natural Order Rosaceae. It forms a handsome tree from ten to twenty feet in height; the greyish-white flowers are produced in pendulous racemes and are very fragrant. The leaves are oblong, rugose, glabrous above and pubescent beneath. The small, ovoid fruits are orange-yellow and about the size of Crab-Apples, they have a slightly acid flavour, and are excellent for stewing or for preserves.

Eriobotrya japonica thrives in most sub-tropical countries, and it is largely cultivated in France, where considerable quantities of fruits are gathered annually and sold in the markets. In the west of England it is grown as a flowering shrub, for which it is well adapted.

At Maxwell's Hill, Malaya, several trees have been established at an altitude of 4,000 feet and several fruits have been produced.

Plants may be propagated from seeds, but budding or grafting may also be successfully effected. *F. S. Banfield, F.L.S., Perak.*

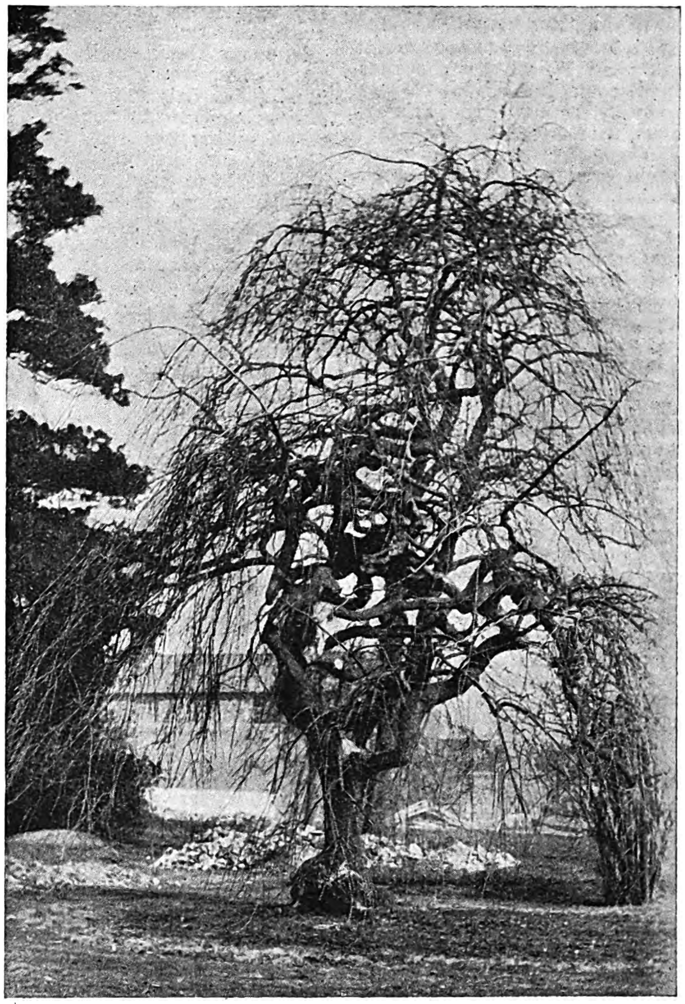

FIG. 127.—A CONTORTED SPECIMEN OF FRAXINUS EXCELSIOR AT MANOR HOUSE, STANMORE.

EXPERIMENTS IN PROPAGATION.

I would here like to put on record some experiments in propagation which, although probably not new to many readers, show ways which are by no means common. It is usual for gardening writers to emphasise the importance, and it is almost insisted on as indispensable, of cutting the shoot chosen for a cutting just below a joint. As I found that this practice usually gave very good results, I have made it the mainstay of my propagating practice, but being of an enquiring turn of mind, I have often made experiments of other methods, and have now arrived at the conclusion that there is not a universal necessity to trim the cutting in this way. In some cases, I am of opinion that this kind of trimming is not only unnecessary, and occupies more time, but that cuttings cut as "internodal" cuttings root more freely and quickly than those trimmed just below a joint. Whether this can be applied to most of the plants which are propagated from cuttings can only be known by experiment. Experiment on an extensive scale is not open to a gardener in private practice, for want of opportunity, of time, and sometimes because his stock of plants is limited and he cannot gamble with it when he is sure of success by the older method.

Some of the plants which I have propagated by internodal cuttings with success are Verbenas, including V. venosa, Nepeta Mussinii, Diplacus (Mimulus) glutinosus, Heliotrope, Antirrhinums, Nasturtiums, Tomatos, Calceolaria amplexicaulis, Fuchsias, Cerastium, Hydrangea hortensis, Tree Lupin, Rose (in spring), border Chrysanthemums, Lobelia, Ageratum, Pansies, Aubrietia, Petunia and Ivy-leaved Pelargoniums, and I am quite convinced that there are innumerable other plants which could be added to this list.

It may reasonably be asked what advantage there is in this method. The reply is that it is simpler and entails less time in preparing the cuttings. In the usual way, pieces are cut from the plants and are then cut below a joint, and as most of them have two leaves near the lowest joint, these have to be trimmed off, making three operations with the knife. Now, with internodal cuttings, one cut only suffices, if that cut is made almost immediately above the joint, as there will be in most cases sufficient length of stem for burial in the propagating compost without cutting away any more leaves. For nearly all cuttings treated in this way, I do not use a knife at all, but merely a pair of pocket scissors.

In nearly every case I use pure sand for propagation, and here, again, there is considerable saving in time. A layer of leaves or some similar material is placed in the bottom of the propagator, and covered with about three inches of sand. I have in several places used local sand, procured from a builder, but I always like it to be rather coarse. This I pass through a fine-mesh sieve to eliminate stones and other foreign matter, and after levelling the surface I give it a thorough watering, with a rose on the water-can, making sure that all the sand is saturated. I insert the cuttings at once. Those which have a stem sufficiently stiff, I press into the wet sand, but where the stem has not sufficient firmness for this, I make a place for its reception with the blade of a small penknife, put in the cutting, and then press back the sand so as to hold the cutting erect. There is no need for the old advice to use a blunt-ended dibber, or to make sure that the propagating material is pressed so firmly against the stem of the cutting that an attempt to withdraw it by one of its leaves would leave a portion of the leaf between finger and thumb. This was at one time a test of proper insertion of cuttings. After all the cuttings are inserted, I get the sand close up against the stems of the cuttings and ensure that there is no air cavity below, by simply watering again with the rose on the can until the sand is washed against the stem and there is no space around the cutting. The propagator for such cuttings need not be an elaborate one. It need only be a deep box set over the hot-water pipes, but not in close contact with them. I find that loose sheets of glass are better as a covering than a hinged light. With a hinged cover you have to wipe off the inner coating of moisture, whereas when loose sheets of glass are used all that is necessary is to reverse them about twice a day, and the moisture which has collected on the inner surface will evaporate when exposed to the atmosphere of the plant house.

I might here give a few instances of successful propagation. Last year, I had the idea that the heavy soil here would not ensure Nepeta Mussinii keeping well through the winter, and as I had planned for a considerable number of these plants, I thought it better to pot up a few plants to hold over the winter as stock for spring propagation. I took up two plants, which were each potted into a five-inch pot. In the early part of the year, I put these into a warm greenhouse, and when young growths were available these were snipped off with the scissors and rooted in the propagator made in the manner already explained. By thus rooting the cuttings as they came along, boxing them up when rooted, and later taking off the tops of the rooted cuttings, I was able from these two plants to secure 718 plants, all of which did well and made large flowering plants during the summer. All the cuttings were internodal ones. The stock could easily have been increased still further had there been the need. Another example of express propagation, which may interest readers, was with the herbaceous Phlox. I obtained during the last week in December, 1927, three pieces of Phlox, variety Elizabeth Campbell, each of which just covered the palm of the hand. I wanted to get a stock from these, so put them in a vinery to induce them to produce growths which might be used as cuttings. This they very soon did, and these, as fast as they came along, were rooted as internodal cuttings. So successful was the propagation that I was able during April to set out 299 plants, by far the majority of which flowered in 1928. During the past spring, I tried the plan again, potting up twelve plants in six-inch pots. I did not here require a very large quantity, but I have now from these twelve stock plants over 150 plants, all of which have had good heads of flowers. At one time, when the variety of Pelargonium named Paul Crampel was not so common as at present, I had a stock of twenty-five plants dug up from the beds in the autumn, and wished to work up a large stock for planting in the following spring. I took them into a warm greenhouse, and so soon as any of the growths was an inch or two long, I used them as cuttings, with the result that by the following May I was able to plant out nearly five hundred plants.

I suppose that the practice of working up a stock of Antirrhinums by taking cuttings in the spring is not a usual one, but at one time I was faced with the difficulty of wanting more Antirrhinums than I had pricked off. This was about the beginning of April. It was rather late then to sow seeds with any hope of the plants flowering until late in the summer, but I tried snipping off the tops of the seedlings which were raised from seeds sown in January, and as these rooted in a little over a week, I took off the tops of all the plants I had and rooted over ninety per cent. of them. They made good plants and flowered only a week later than those from which they were taken, and later in the season it would have been impossible for anyone to state which were seedlings and which were from cuttings. I also adopted this plan extensively this year with quite satisfactory results. It applies also to Petunias, Verbenas, Aubrietias and Pansies. All these were increased by internodal cuttings, with the exception of Pelargonium Paul Crampel.

Another interesting trial was with Tomatos. It was on April 30, a few years ago, that I was taking out the side growths from Tomato plants, and thought that I would ascertain whether these growths would root, and if so, whether they would make good fruiting plants. The shoots were rubbed off with the finger and thumb in the usual manner, and to make surer of their rooting, I made a clean cut at the bottom of each piece (these were little more than an inch long). I dibbled them into the sand propagating bed, and in exactly a week I was able to remove them and put them into small pots. They were grown on in the usual manner and fruited well, producing fruits quite close to the base of the plants.

It is known to most Sweet Pea growers that cuttings may be taken of these, although my experience is that the resulting plants are not so strong as seedlings. When I have tried them, I have usually made use of the pieces removed when taking out the tops of the plants in winter or early spring, but on another occasion I am going to try cuttings of some of the growths which spring from the base of the seedlings after the pinching has been done, as I think that they would make stronger plants. I have four circular groups of Sweet Peas from cuttings this year, and anyone who did not know how they were obtained would find it difficult to state with any certainty which groups were from cuttings and which from seeds. The plants from cuttings started to flower a little sooner than the plants from which they were taken. I do not recommend this practice as a general rule, but it may be useful to know of the method should there be a loss of plants in the spring from any cause.

Although I have spent over thirty years gardening, I have never yet seen anyone propagate rambler Roses in the same manner as is usual with Loganberries, that is, by layering the tips of growths of the current year. I was at one time engaged in this interesting method of propagating Loganberries, and when going to a meal, I passed some rambler Roses. It then struck me that the habit of growth of the Loganberry and the rambler Rose was very similar, and perhaps the same method of propagating them might be adopted. I tried a few and waited anxiously for three weeks, when my curiosity would brook no further delay, so I examined the growths, to find to my joy that roots were being formed. I then layered fifty growths of a rambler which, if my memory serves me correctly, was The Garland, and in about eight weeks I was able to remove them from the parent plant, for each of them had rooted, and had started to throw up young growths.

I wonder whether any other gardener has tried rooting the leaves of Carnations. I noticed on one occasion that a leaf which had been partly broken from a perpetual-flowering Carnation of the variety Britannia, had started to "callus." I removed it, put it in the propagator, and in a short time I was delighted to find that several roots had formed. I potted it up, but although it made a much larger root-system, there was never a suspicion of any growth from it, nor was I able to get any other leaves to grow, although most of them formed quite a number of roots. I do not see that there would have been any advantage in this method of propagation, even if it had proved possible to raise a growing plant in this way, but one likes to make these trials, even if they come to nought.

A few years ago, I was able, with internodal cuttings, to work up a large stock of Heliotrope from a comparatively few cuttings. I wanted to fill several large beds with the variety Lord Roberts, and was able during February to get one hundred cuttings. These I rooted in the sand propagator, and when they were rooted, I boxed them up. In rather more than a week I cut off the tops with scissors and put these also in sand. I continued this method until the end of April, when I finished propagation, but was able early in June to set out 1,200 plants from three-inch pots. *William F. Rowles, Sussex.*

WOODLAND GARDEN.

CORNUS CANADENSIS.

As autumn approaches we look for the entry of the pretty Cornus canadensis into greater prominence than it secured earlier in the season. It is still producing its tiny, inconspicuous flowers surrounded by broad white bracts, and its leaves are beginning to assume the brilliant tints which constitute perhaps the greatest charm of this little plant. It loves the shade and rather peaty soil, but is not so particular regarding the latter as is imagined, and grows very well in loam and sand. But it should have a fair amount of moisture, and where it receives a certain amount of sun, this is naturally more essential than when in shade. When happy, it soon forms clumps and masses by means of its underground stems, from which arise the short, leafy branches.

It is a plant which was introduced from Canada so long ago as 1774, but is not too common in nurseries, as I found on receiving several enquiries from would-be purchasers asking where C. canadensis could be obtained. It is not one of the "cheap" plants which betoken a large demand, and, in consequence, increased propagation by the trade. C. canadensis is quite hardy. *A.*

BULB GARDEN.

TULIPA ORPHANIDEA VAR. WHITTALII.

This delightful Tulip has been accorded specific rank as Whittalii, and as such I received it, some years ago, from the late Mr. H. J. Elwes; it is now, however, usually considered a varietal form of the Grecian species, T. Orphanidea, the flowers of which display the variability so characteristic of many Tulips, in charming shades of pale orange to rich brownish-crimson.

T. Orphanidea var. Whittalii is of sturdy growth, with goblets of copper suffused and flushed with sunset-yellow; it is a mid-season Tulip, flowering generally between the main body of species and the late ones, as represented by T. montana, T. Gesneriana and T. Sprengeri.

With me, this Tulip grew strongly and flowered splendidly in a well-drained border with a western aspect; it is still, I think, somewhat rare, and is a Tulip of undeniable beauty and considerable decorative or garden value. *R. E. A.*

MESEMBRYANTHEMUM.

(*Continued from p.* 249).

MITROPHYLLUM, Schwant.

8.—M. nanum, N. E. Br.—Plant dwarf and tufted, less than an inch high. When at rest the flowering growths are covered below with 2–4 coriaceous, blackish sheaths, that are often oblique and longitudinally rugose. Growths, when at rest, half-moon-shaped, 2–2½ lines broad and 1–1¼ line thick, length not stated. Free pairs of leaves sub-clavate; the second pair united to their tips. Flowers sessile. Calyx 6-lobed, with the ovary-part globosely pear-shaped. Petals white, only a very old flower examined. Stigmas 6, twisted together, nearly 2½ lines long. Ovary slightly depressed at the centre on the top. Capsule 3½–4½ lines in diameter; valves blackish within; expanding keels sub-triangular, adpressed and flattened, with toothed edges and broad marginal wings; cells roofed with cell-wings. Seeds ¼ line long, globosely obovate, pallid.

Conophyllum nanum, L. Bol., *Notes on Mesemb.*, Vol. II, p. 51.

Clanwilliam Division: Between Twenty-four Rivers and Porterville, on clayey soil. Leipoldt.

I have not seen this plant, but it seems to be closely allied to one that Dr. Tischer has described or is about to describe, under the name of M. Schickianum, Tisch., which is a stemless species about 1½ inch high, with the cone-leaves about 5 lines thick, tipped with leaf-points 5–6 lines long. *N. E. Brown.*

(*To be continued.*)

MITCHAM PEPPERMINT.

The cultivation of aromatic plants for the sake of the essential oils which they contain constitutes a very important branch of horticulture, the oils in question finding many applications as flavouring agents and in the perfumery and other industries. They are also, in many cases, used medicinally. Aromatic plants are cultivated for this purpose, and their oils are distilled in many parts of the world. The centre of the essential oil industry is situated at Grasse, in the south of France, described some little time ago in *The Gardeners' Chronicle* (Vol. LXXXIV, p. 225), the oils distilled at Grasse being, in many instances, the very best obtainable. In the case of two plants, however, those grown in England yield oils of a much finer aroma than those grown elsewhere. These are Lavender and Peppermint.

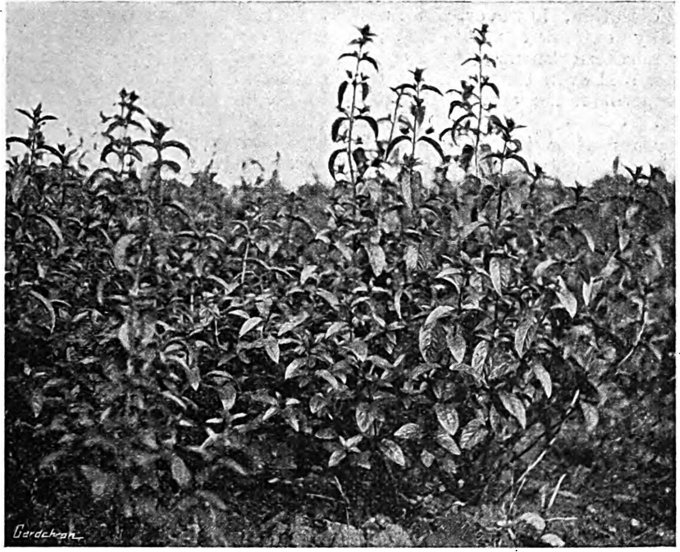

FIG. 128.—PEPPERMINT PLANTS (MENTHA PIPERITA).

Peppermint has been cultivated commercially at Mitcham, Surrey, on the outskirts of London, since the middle of the eighteenth century; and, although the activities of the builder have made serious inroads on the land available for the purpose, Peppermint still forms an important crop in the Mitcham district. It may be added that the plant is also cultivated elsewhere in the south-eastern and eastern counties, as well as in many other parts of the world.

The Peppermint, Mentha piperita, L., belongs to a critical genus, in which many hybrids and varieties occur. M. piperita itself appears to be a hybrid, its parents being M. aquatica, L., and M. spicata, Huds., and several varieties of it are recognised. It is found wild in Britain.

The chief characteristics of the plant (see Fig. 128), in addition to its odour, may be briefly summarised as follows:—The flowers are borne in terminal spikes, interrupted below. The leaves are shortly stalked, ovate-lanceolate, coarsely toothed and glabrous or nearly so. The lower part of the calyx is devoid of hairs. The plant produces an abundance of subterranean stolons, whereby reproduction is effected, the flowers rarely producing seeds.

The variety distinguished as Black Peppermint, which is the one mostly cultivated at Mitcham, has flowers of a deep lilac colour, and the stem and leaves are more or less tinged with purple. The variety known as White Peppermint has leaves of a brighter green, flowers of a paler hue, and leaves less markedly toothed. It is stated to produce an oil of finer flavour than the "black" variety, but the yield is less, and the plant not so robust in its growth.

It may be noted in passing that a variety of Peppermint distinguished as var. citrata, Ehrh., differs markedly from those above described, inasmuch as its odour somewhat resembles that of the Bergamot. It is sometimes regarded as a distinct species, and has also been referred to as a glabrous variety of M. aquatica.

Those who love simplicity, when confronted with a modern list of Mentha species, hybrids and varieties, may consider that the "splitters" have been hard at work. Actually, however, minute differences are of the greatest commercial importance in connection with Mints, as oils produced from plants which apparently differ from each other very slightly may possess markedly different aromas. Although all the foreign Peppermint oils, the Japanese excepted, are distilled from varieties of M. piperita, the English oil, and especially that obtained from plants grown at Mitcham, possesses a distinctive aroma and can command a price much in excess of that of its competitors.

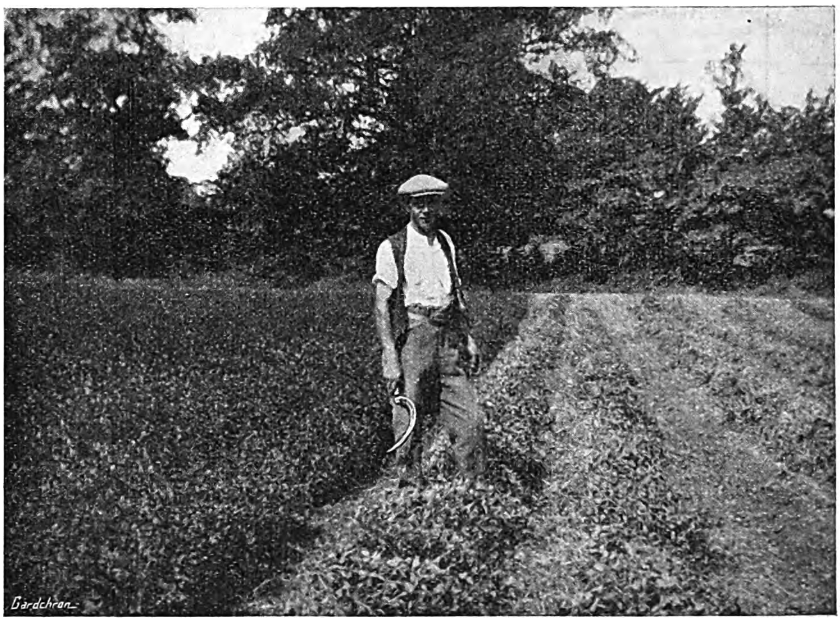

FIG. 129.—HARVESTING PEPPERMINT ON MESSRS. J. AND G. MILLER'S FARM AT MITCHAM.

The plant is very susceptible to climatic conditions, and would appear to undergo variation in accordance with these. I have been informed by one of the leading Mitcham growers that some time ago he exchanged a number of roots with an American grower for roots of the M. piperita variety cultivated in the United States. The first year, the plants more or less maintained their distinctive features. Afterwards, the American plants grown at Mitcham assumed the character of British plants, while the Mitcham plants grown in America were stated to have undergone exactly the reverse transformation.

This year, the continued drought has caused the harvest at Mitcham to be a poor one, for the plants require plenty of rain in the early part of the year, followed by an abundance of sunshine. The harvest takes place in August, and the plants are usually cut by hand, small sickles known as "Mint-hooks" being used for this purpose (Fig. 129). M. piperita is a perennial, although the first crop is usually the best, and, after three years, the quality of the plants rapidly deteriorates. New fields are created by pulling up the young, rooted shoots which form in the spring, and dibbling them in suitable ground about a foot or more apart. The earlier this can be done, the better is the crop. A light, rich soil is desirable, and effective weeding is extremely important. M. arvensis is a common weed and, if not removed, may very seriously mar the quality of the oil.

The oil is obtained by distilling the plants with steam, often, but not always, after they have been partially dried. The oil, being insoluble in water, separates in the distillate and can be purified by filtration and, if desired, by further distillation. At Messrs. J. and G. Miller's distillery, which the present writer had the pleasure of recently inspecting while the work was in progress, distillation is effected in copper stills holding round about a ton of material. Direct heating is avoided, this method, adopted in primitive types of stills, being liable to char the plants with disastrous effect on the aroma of the oil. The receivers, into which the water containing the precious oil runs, are enclosed in locked cages. It is thus possible for farmers to bring their crops of Mint to be distilled with perfect assurance that the oil will not be tampered with, each farmer having his own padlock, the key of which remains in his possession while his Mint is being treated.

The uses of Peppermint oil as a flavouring agent are very numerous, although, for many purposes, the cheaper foreign oils are employed in preference to the *de luxe* Mitcham product, which finds one of its chief applications in the manufacture of that delicious liqueur, crème-de-menthe. *H. S. Redgrove, B.Sc., A.I.C.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* Publisher; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* Editors. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

RHODODENDRON REPENS AND ITS ALLIES.

When Sir Isaac Bayley Balfour, dealing with the Chinese Rhododendrons, founded the sub-series Forrestii of his series Neriiflorum twenty years ago, it comprised one species, then unique, viz., Rhododendron Forrestii. In 1914, Forrest's collectors found R. repens, although it was not until 1917 that this species was collected in flower. In the same year, R. erastum and R. porphyrophyllum were collected, and in the following year R. serpens—all by Forrest's men. These five species, with R. pyrrhoanthum, Balf. f.—a species I cannot trace—form the sub-series Forrestii.

Nothing has since been heard of R. Forrestii—or, indeed, of the others; and although Bayley Balfour* and Forrest both regarded R. Forrestii as a good species, in the writer's opinion it is no more than, at most, a form of R. repens.

K.W. No.	Habit.	Leaf.	Pedicel.	Calyx.	Corolla.	Stamens.	Ovary.
8283 **8336** **(R. repens)**	Prostrate, flowers solitary, rarely 2, lying on or near the ground.	Oval or narrow-oval, 4·3 cms. long, 2·3 cms. wide; acute.	Glabrous.	An angular rim, glabrous.	Tubular bell-shaped, glabrous, scarlet.	Anther chocolate; filament quite glabrous, white.	Clothed with interwoven, translucent, white hairs. Style crimson, glabrous.
8341	Sub-prostrate, branches ascending. Truss 3-4-flowered.	Oval, 5 cms. long, 3 cms. wide.	Scattered, crimson-headed, glandular hairs.	An angular rim, edged with crimson-headed, glandular hars.	Bell-shaped, pink.	Anther orange-brown; filament pubescent at base.	Clothed with scattered, stiff, crimson-headed, glandular hairs.
8345	Sub-erect, branches ascending, 2-3 feet high. Truss 4-5-flowered.	Oval, 6 cms. long, 3·2 cms. wide.	Glabrous or almost so.	Large, scarlet, enclosing ovary; glabrous, except for a few scattered glandular hairs on rim.	Bell-shaped, white, flushed pink.	Anther red-brown; filament pubescent at base.	Clad with interwoven, translucent, white hairs
8362	Sub-erect or ascending. Truss 2-4 flowered.	Narrow-oval or elliptic; 5·7 cms. long, 2·3 cms. wide.	Hairy, Hairs white or buff; more or less interwoven, but scattered.	An angular, rim-like collar; glabrous.	Bell-shaped, scarlet.	Anther black or purple-black; filament carmine, glabrous.	Clad with closely interwoven translucent white or buff hairs, style glabrous.
8363	Sub-erect or ascending.		Scattered crimson-headed, glandular hairs.	Small, red, the rim beaded with glandular-headed hairs.	Narrow, bell-shaped, pink, with 5 small, crimson pocket-glands.	Anther brownish-yellow; filament pubescent at base.	Loosely covered with short, colourless, glandular hairs; style colourless.

Of this plant we now know much more than we did in 1917, when it was first collected in flower in north-west Yunnan. Although the specific name repens is, of course, admirable, it seems unfortunate that the name Forrestii was not attached to this beautiful plant. If, indeed, they *are* the same, the latter name has priority; but it is hopeless to attempt to dislodge a name as firmly fixed in the saddle as repens—a point which priority-fanatics ignore.

While discussing the question of R. repens and R. Forrestii, Bayley Balfour gives an outline of the characters possessed by the members of this group as he conceived them.† The plants, however, differ in certain fundamental characters; some have so many as three to four flowers in a truss, others have glandular hairs on the leaves, but all have a *more or less* creeping habit, the branches, when prostrate, rooting freely. In the field, however, one finds a fairly regular gradation from the *absolutely* prostrate R. repens, with solitary flowers, to underscrub plants with flowers in distinct trusses of three to four flowers; obviously, a plant bearing a loose umbel of flowers must have the stems ascending—at least it cannot be strictly prostrate. The writer would, in fact, retain in the sub-series Forrestii only those plants which are absolutely prostrate, which have solitary flowers, themselves prostrate, and glabrous leaves. Such an admission would rule out R. erastum, which has several flowers in a truss, and R. porphyrophyllum, which has the under-leaf surface hairy. Probably the only species remaining would be R. repens; but how much more widely distributed is it than was formerly believed! Bayley Balfour believed it to be endemic in north-west Yunnan, where it was first discovered on the Mekong-Salween divide; nor has it ever been found east of the Mekong. In the opposite direction, however, its area has been gradually extended until it now embraces all far northern Burma, the Assam frontier mountains, and even the main Himalayas, where that great range crosses Kongbo province, in Tibet.

In 1919, five years after its discovery, I found R. repens in fruit only, on Imaw Bum, so far south as 26°N. on the Burma-Yunnan frontier. Apparently Farrer did not meet with it on the Chimili Pass that year, since it is not mentioned in Mr. Evan Cox's excellent book;* Farrer did, however, meet with it further north on the Chawchi Pass (same range) in 1920. I suspect it to occur on the Chimili also, although sparingly; it was very rare on Imaw Bum.

In 1924 I discovered R. repens in Tibet (!) on *both* sides of the Tsangpo immediately above the great gorge, 350 miles almost due east of Lhasa. Since it does not occur in Sikkim and has not been recorded from Bhutan, this locality must be close to its western limit. Its discovery on Namcha Barwa was almost revolutionary—the first record of a Sanguineum Rhododendron from the Himalayas; for there can, I think, be no reasonable doubt that Scarlet Runner (K.W. 5,845) *is* R. repens, or at most a geographical form of it. Namcha Barwa, it is worth noting, is 350 miles in an air line north-west of where R. repens was first found. In 1926, I found R. repens again at the headwaters of the Irrawaddy, and in 1928 on the Mishmi Hills, Assam frontier; thus establishing the connection between the Yunnan and Tibetan localities. We are thus enabled to plot its area of distribution quite definitely; and not only its distribution, but those of its nearest allies also. We find, in fact, that R. repens and Co. occur at the wet, alpine ranges between the meridians of 94°E. and 99°E.; altitude, 10,000 to 12,000 feet; climate, seven months under snow, five months rain and mist. This is practically the distribution of Primula Agleniana and Co. although no member of that firm has quite the distribution of R. repens. It is another illustration of the unity of the Sino-Himalayan alpine flora.

We have now to consider the distribution of a number of Rhododendrons obviously allied to R. repens, although differing from it in several important respects. The distinguishing characters of R. repens are, the prostrate habit, glabrous leaves lying flat on the rock, flowers scarlet, without spots, solitary at the ends of the shoots, and prostrate; so large are they and so flat the branches that, although lying on their side, they usually overtop any other part of the plant.

The species to which I am about to refer have the glabrous, rounded leaves of R. repens, but the flowers are in trusses of three to four, and thus are not prostrate. The plants, in fact, form low, gnarled bushlets, rising nine to eighteen inches from the ground, and spreading until they may be so much as two feet through. Looking at the leaves only, one might perhaps take these plants for a variety of R. repens, which certainly has variable leaves, although they are usually pointed, not rounded. Mr. Hutchinson has, indeed, expressed himself to the writer in favour of that view, as regards one plant ('Carmelita') at any rate. But no botanist who had ever seen these two plants, that is to say, R. repens and 'Carmelita,' growing side by side, and watched them flower and fruit, could believe that for a moment. It is quite definitely wrong. These species are as distinct as two closely allied species of Rhododendron could well be.

The species I intend to deal with here—none of which has apparently been legitimised yet, are the following:—Carmelita (K.W. 5,847), Doshong La, Kongbo, Tibet, 1924; Scarlet Pimpernel (K.W. 5,846), Doshong La, Kongbo, Tibet, 1924; Rose of Kaso? (K.W. 6,935), Seinghku Valley, Burma-Tibet frontier, 1926; Rose of Kaso (K.W. 8,341), Mishmi Hills, Assam-Tibet frontier, 1928.

It seems to me that R. erastum, R. porphyrophyllum and the rest should come here, and not associate too closely with the unique R. repens. 'Carmelita' was the pet name given to the first of these semi-prostrate entanglements. It has flowers of a softly-glowing carmine. 'Scarlet Runner' sprawled flat on the granite slabs in full exposure to sun and rain, wind and snow, in splendid isolation, and not far away 'Carmelita' crouched in the rock hollows, forming, with other species, bushlets nearly a foot high and as much through. These plants derived some protection from their position, in consequence of which they were buried under snow in October, unopened capsules and all, when 'Scarlet Runner,' naked on the sunny rocks was broadcasting its seeds. 'Carmelita' indeed ripened its seeds, at any rate, that year, a good fortnight after 'Scarlet Runner.'

One of the species which grew with it was the closely allied 'Scarlet Pimpernel.' This had flowers of a darker colour than 'Scarlet Runner'—a rich crimson blood-red, in trusses of four, like 'Carmelita.' Both species were much rarer than 'Scarlet Runner.' In 1926, I found in the Seinghku valley at 11,000 feet altitude a solitary plant with the foliage and habit of 'Carmelita.' It was over, but one or two moribund flowers hinted that they had once been pink. In the autumn, I found another plant covered with capsules, under a gneiss rock in a half-sheltered gulley at 12,000 feet. It was obviously a very rare species.

In 1928 in the Mishmi Hills, Clutterbuck

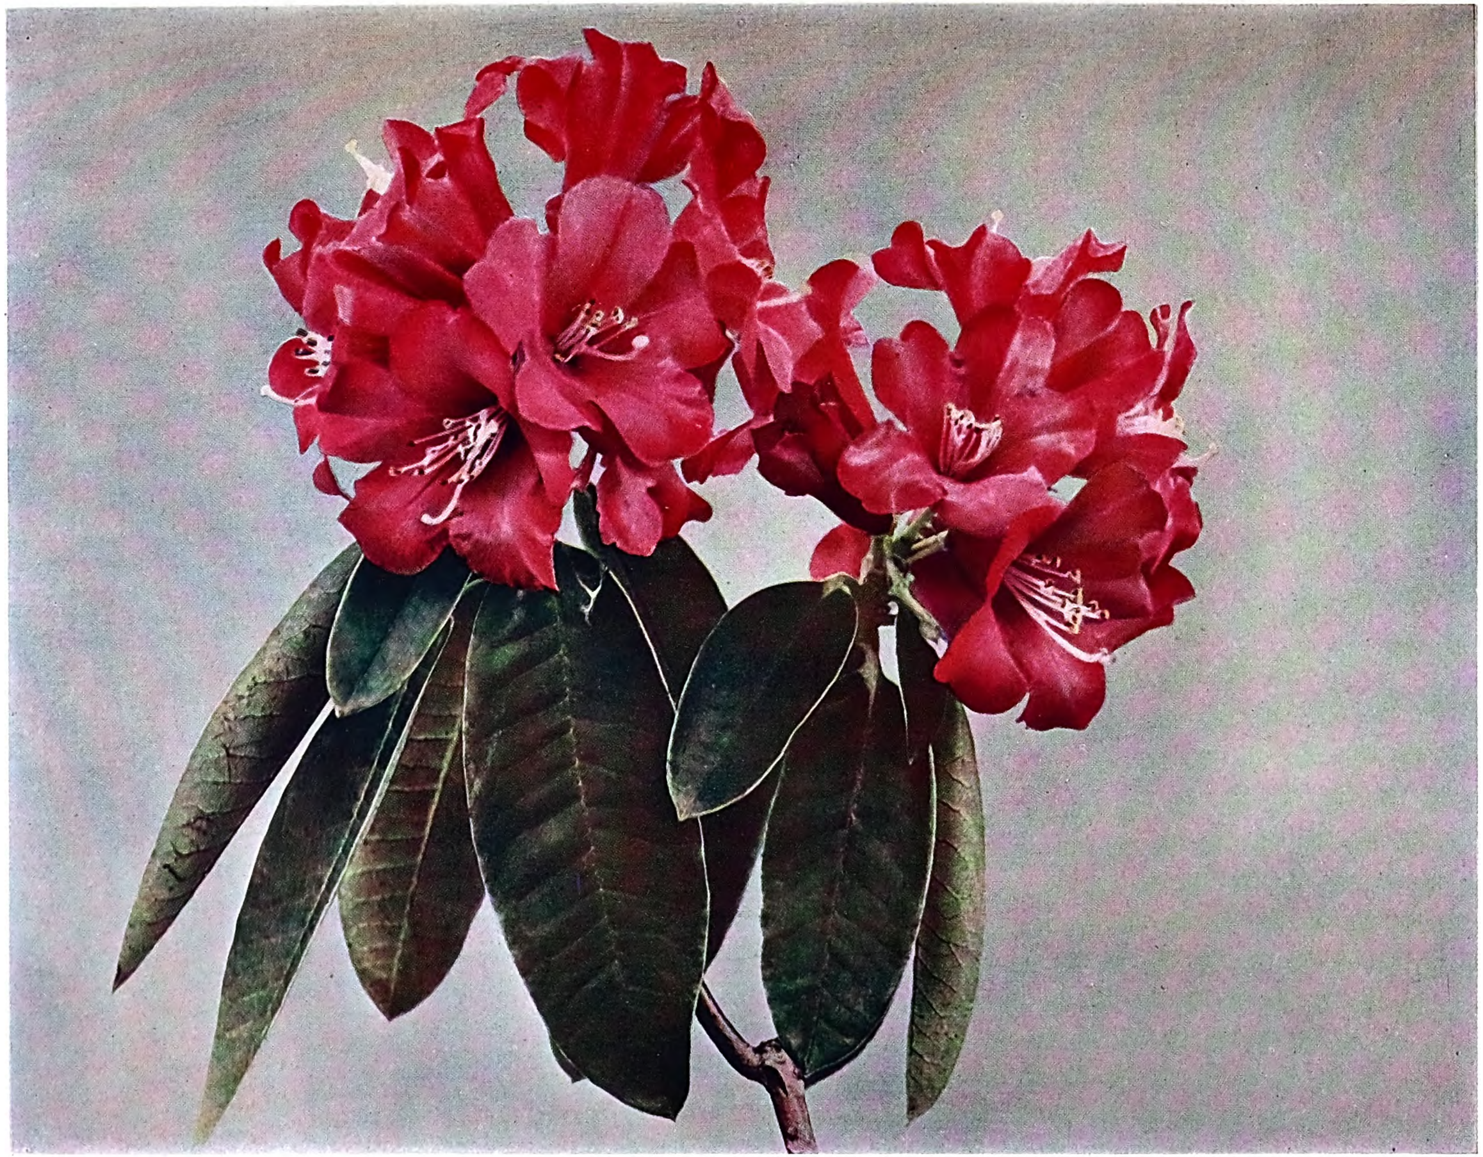
Supplement to "The GARDENERS' CHRONICLE."



RHODODENDRON KING GEORGE.

and I found 'Rose of Kaso,' flowering in mid-June at about 12,000 feet altitude. In habit and foliage it resembled 'Carmelita,' with flowers of a delicate shell-pink, like those of R. Williamsianum. This species grew scattered in dense scrub thickets of 'Sanguineum' and other Rhododendrons, and was much the rarest species on the mountain. R. repens curtained the barest rocks hard by and was common enough. I have little doubt but that the Seinghku plant was this same 'Rose of Kaso.' While there can be no question that the three plants described are quite distinct, I found the half-dozen scattered plants we collected on Kaso to vary a good deal in minor points; especially in hairiness and in pigmentation. After careful comparison, I tabulated them as shown on page 226; but in spite of these differences, which look more formidable in the table than they did in the field, I am convinced that Nos. 8,341, 8,345 and 8,363 represent one species—'Rose of Kaso.' This plant flowered at least a fortnight later than R. repens; and where the thick underscrub—which included, besides scattered plants of 'Rose of Kaso,' R. sanguineum, R. calostrotum and R. brachyanthum—thinned away, there on the exposed frontier R. repens plastered the rock—alone.

No. 8,362 is more puzzling. Is it R. repens, growing more luxuriantly in a slightly less exposed position? To admit that is, perhaps, to betray 'Carmelita,' 'Scarlet Pimpernel,' and 'Rose of Kaso.' But I do not admit it. R. repens may occasionally bear two flowers on a shoot, but that is casual and exceptional. Its nature is to bear one; and where there is more shelter, R. repens does not grow more luxuriantly; it does not grow at all, being replaced by several other species. No. 8,362 may *look* something like a transitional species, but if so, why is it not more common? It ought to occur wherever R. repens occurs; but, on the contrary, it is very rare. Is it 'Scarlet Pimpernel'?—Possibly. Or is it another species of the same set? Unfortunately there are few or no seeds of it from the Mishmi Hills, although there may be a few from the Seinghku valley, under another number.

As regards colour, this ranges from crimson-scarlet, through carmine to pink. R. repens, however, is always a fierce scarlet. The only exception I have ever seen was a solitary plant with a solitary cream-coloured flower, in the Seinghku valley. I attached a metal ticket to it, and recovered it in October. Alas! it set no seeds. As a matter of fact, R. repens seeds very poorly for a Rhododendron. Where one had seen nothing but a sheet of scarlet flame pouring over a rock in June, one may pick up half-a-dozen capsules, with luck, in October. It is always thus. 'Rose of Kaso' seeded ill in the Mishmi country, but not so badly in the Seinghku valley. 'Scarlet Pimpernel' and 'Carmelita' also set fairly well.

The 1928 season in Assam may, therefore, have been capricious. One would expect these scrub species to fruit as well as the other 'Sanguineums' among which they grow, and that is profusely. Their large, gaily coloured corollas, although apt to be partly hidden among the leaves, are well protected against rain, by inversion, and should be freely visited by insects and birds. But who is going to crick his neck, crack his skull, or tear his wings, by diving at 'Scarlet Runner'? There it lies on the ground, glowering in a red rage, and the flighty creatures just ignore it. The only insects I have ever seen inside the corollas of 'Scarlet Runner' are ants; and *they* do not cut much ice.

R. repens is now a well established plant, at least, in favourable localities, and there seems no reason why we should lose it. At Edinburgh and elsewhere it flowers freely every year, and attracts a lot of attention. This is the plant introduced by G. Forrest. 'Scarlet Runner', which may or may not prove a more accommodating variety, has not yet flowered in this country. The same is true of 'Scarlet Pimpernel,' 'Carmelita,' and 'Rose of Kaso'; all are growing strong, and there are a fair number of plants, but they have still to flower and prove themselves. The first two have been collected only once; 'Rose of Kaso' has been collected twice. Thus there is room for more gatherings if they prove all that is expected of them. It is possible that there are more of these semi-prostrate 'Sanguineums' still undiscovered. They are rare plants, and if not found in flower are almost bound to be passed over; and the appalling country which they honour with their presence has been little enough explored. *F. Kingdon Ward.*

PLANTS NEW OR NOTEWORTHY.

EMMENOPTERYS HENRYI, Oliver.

THE illustration, Fig. 130, depicts a tree of Emmenopterys Henryi, one of the most interesting and remarkable of the many new trees introduced to our gardens from China during the present century. It was first described by Professor Oliver from dried specimens collected by Prof. Augustine Henry, in Hooker's *Icones Plantarum*, Vol. XIX, t. 1,823, in 1889.

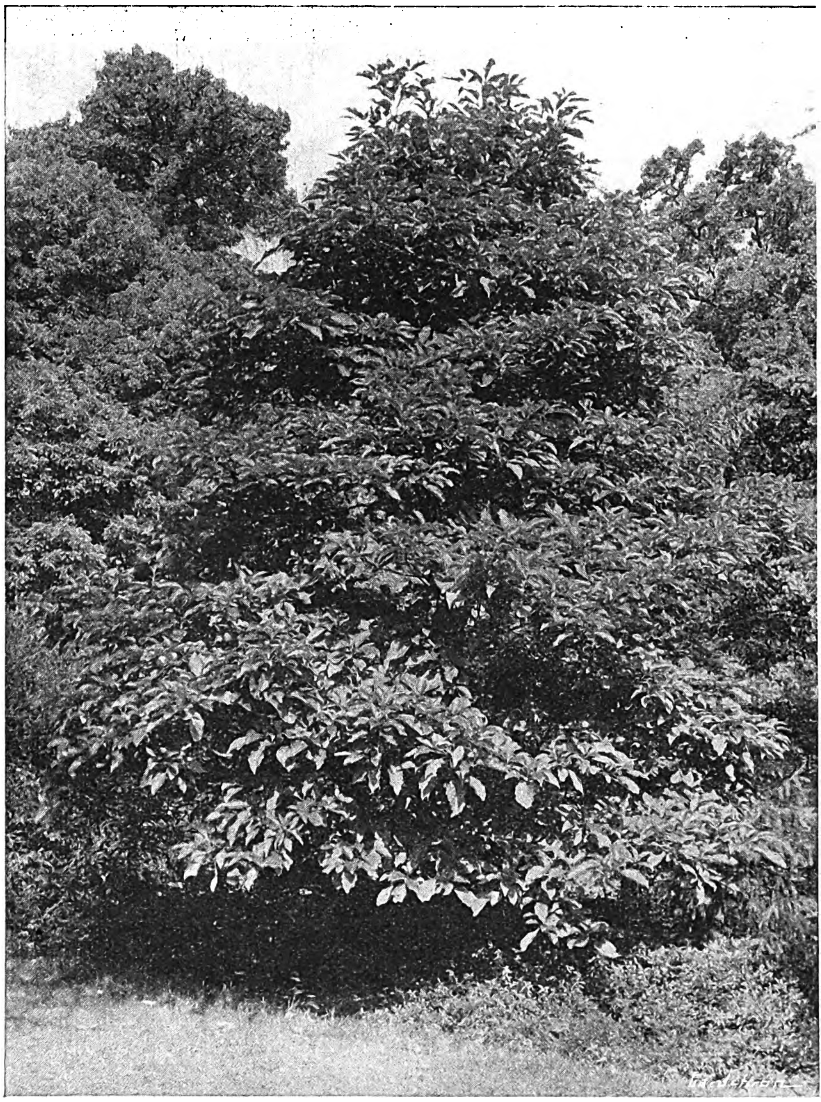


FIG. 130.—EMMENOPTERYS HENRYI.

Mr. E. H. Wilson collected specimens in June, 1900, during his first expedition on behalf of Messrs. James Veitch and Sons, but I think I am correct in stating that it was not until November, 1907, that Mr. Wilson was successful in collecting ripe seeds. It was from these seeds (Wilson No. 622) that plants were raised in the Coombe Wood Nursery. The specimen illustrated is one of these seedlings and was obtained from the nursery for Kew in 1913. It is now about twenty feet in height and growing freely.

Mr. Wilson describes Emmenopterys Henryi as one of the most striking and beautiful trees of the Chinese forests. It is a fairly common tree in moist forests on the mountains of western Hupeh and Szechuan, at an altitude of 2,000 feet to 4,000 feet. A deciduous tree with a stout trunk and abundant leafage, it attains a height of from thirty feet to eighty feet.

The leaves are up to ten inches in length, and five inches wide, dark green above, with rather prominent reddish veins beneath.

We are anxiously awaiting the development of the first flowers on the cultivated specimens. Dried specimens show that the flowers are borne at the ends of the shoots during July, in flattish to pyramidal corymbs up to ten inches wide and six to eight inches high. The flowers are white, funnel-shaped near the base, spreading towards the top into five rounded lobes, averaging an inch across.

The calyx is normally small, but a remarkable feature is that in some of the flowers one of the calyx lobes develops into a white, Cornus-like bract, sometimes attaining a length of two inches and a width of one-and-a-half inch. This persists on the fruit, gradually changing to a pink or reddish tint. The name Emmenopterys is of Greek origin, meaning persistent, and wing, in reference to the enlarged calyx lobe.

Emmenopterys is a monotypic genus belonging to the Natural Order Rubiaceae, one of the best known members of which is Luculia gratissima. During the severe frosts of last winter, and when the growth buds were swelling in spring, no Chinese tree or shrub was more anxiously watched. Except that it is growing in a moderately sheltered position, no protection was afforded, and at no time has it shown any sign of tenderness. Mr. George Forrest has also collected seeds, and plants of this origin are growing in British gardens. *A. Osborn, Kew.*

PROBLEMS OF PLANT LIFE.*

X.—Breathing Pores or Stomata.

(*Concluded from* p. 248.)

Two important questions yet remain for consideration; the first is physiological, and the other functional; in other words, what are the stomata, and what is their use? It is not enough to state that stomata consist of a pair of guard-cells surrounding an aperture which is associated with intercellular spaces or air chambers. A variety of facts come to light when we begin to examine the stomata under the microscope, by means of chemical reagents, and in other ways, and these have an important bearing on the problem of their use.

It will be clear from what has already been written respecting their numbers that the stomata are extremely small. Tens of thousands may be found on a leaf an inch square. Many years ago, a German botanist, Schacht, found that the stomata of such plants as Arbutus, Butcher's Broom, Holly, Teazle, Aloe and others, were coloured violet or blue under the action of iodine and sulphuric acid, and concluded that the guard-cells were always composed of cellulose. Since his day much new matter has come to light.

It is important to note the relationship which exists between the veins and the stomata of leaves, since the former affect the number and arrangement of the latter. In grasses, cereals and most monocotyledons the veins are straight and parallel (Fig. 131), and the stomata normally have a similar order. Contrast this with their disposition on the leaf of Sycamore (Fig. 132), Lime or Spiraea. Dr. Yapp has pointed out that the stomata in Spiraea or Meadow Sweet decrease in size but increase in number as one takes the leaves in order from below upwards. For example, while a lower leaf had some 390 stomata per square millimetre, another higher up had about 800, while near the top of the stem the numbers exceeded a thousand. Thus, three times as many stomata are found on an upper leaf as on a lower. In technical language, he regards the upper leaves of a plant of this kind as being "more xeromorphic in structure than the lower ones."

This brings us to the problem of function. Why do breathing pores or stomata exist? What end or ends do they serve in the economy of plant life? The question was the subject of heated controversy for a long time among the earlier plant physiologists. As no central orifice was at first observed, partly owing to the poor definition of the lenses in use, the stomata were taken to be glands. Grew, in his *Anatomy of Plants* (1682) held that they were either for the admission of air, or to serve as outlets for superfluous fluid. About the middle of the nineteenth century, Mohl demonstrated that they exist to give a passage to air which shall serve the purposes of inspiration and expiration. But it is not air alone that passes through these pores. It is now known that they have to do with moisture as well, and they have a most important bearing on the flow of sap, the transudation of water, and the behaviour of the plant as it is affected by drought, temperature, and other meteorological conditions.

The guard-cells or lips of the stomata are extremely sensitive, and exhibit the most remarkable fluctuations of movement under varying atmospheric conditions. These fluctuations are not merely mechanical, but are accompanied by well-marked changes of a chemical nature as well. Thus, when the stomata are closed, the guard-cells are full of starch, but as the stomata open, the amount of starch diminishes, and sugars take the place of the starch. It will thus be seen that the study is one of equal delicacy and importance, and this will account for the divergent views which are to be found in recent memoirs.

The leaf stomata are acted upon in a special manner alike by light, moisture and atmosphere. In some instances the stomata close down for the night to give the plant rest. This is not, however, by any means a universal habit. since the Cucumber, Buttercup (Ranunculus acris), and other plants have been observed to keep them open both day and night. Some plants, again, open their stomata in the morning, but soon close them again, this being particularly the case in dry climates. That fact is most suggestive, since it illustrates the relation of the breathing pores to drought, and shows that it is not the air alone which affects them, but moisture as well. When the pores are open, at least two different actions may be performed.

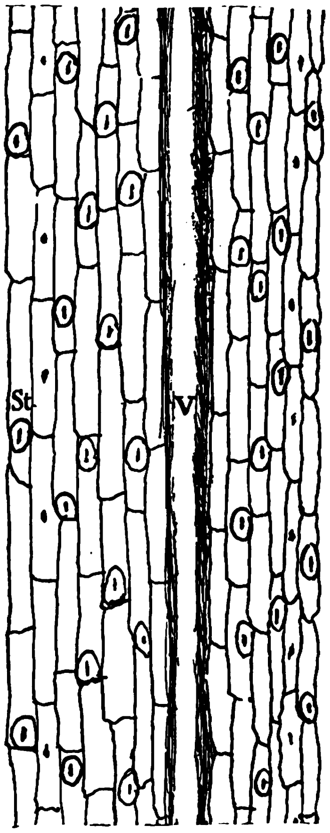

FIG. 131.—RIBBON GRASS.

(V) Vein; (St.) stomata, arranged in parallel rows.

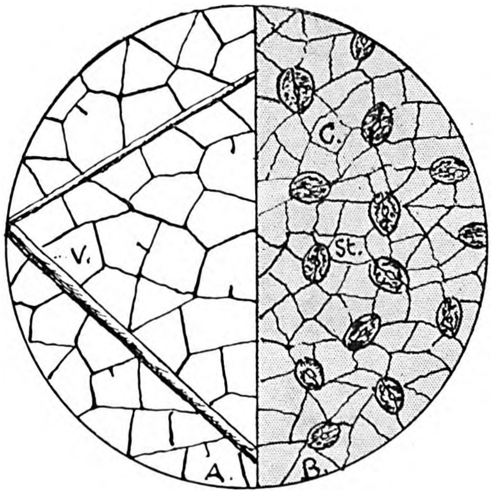

FIG. 132.—SYCAMORE LEAF.

(A) Venation; (B) cell structure and stomata.

On the one hand, carbon dioxide can be inhaled, while on the other moisture can be transpired.

It is well-known that light has a very important influence on stomata. If it is too intense it causes them to close, but most plants open them in normal daylight, and close them gradually at nightfall. Hot, dry winds also affect them, causing them to close. This is a wise provision to prevent excessive transpiration. Since plants are almost all dependent on a free supply of water it is of the utmost importance that they should be able to regulate the supply. In temperate climates, where rain falls at frequent intervals, the tendency is for plants to rely on a constant supply being furnished. Should this prove not to be the case, wilting speedily follows on the slackening of supplies. But in lands which have long periods of drought the plants tend to adapt themselves to these conditions.

It has been often pointed out that we must be on our guard against generalising too freely on subjects of this kind. Thus we have need to beware of over estimating the part played by the stomata in relation to transpiration. We have noticed, for example, that the stomata are usually open during the day. But it is just then that transpiration is the greatest. It follows that we must look on these organs as serving some other end, and recognise that they are as much concerned in the assimilation of carbon as they are in the process of transpiration. The latter function is necessary in order to keep up a constant supply of moisture from the soil, both to give turgidity to the plant and to enable the salts necessary for plant life (which are held in solution) to be well circulated among the various tissues.

I am not able at the moment to recall any experiments which have been carried out to account for one phenomenon which has more than once come under my own observation during periods of drought. It will frequently be noted that after the supply of moisture begins to run short plants will droop or wilt. If, however, no rain falls, certain plants possess the capacity to recover their turgidity and go on thriving as though no drought prevailed. To use a familiar illustration, they get their "second wind." Whether this is due to the stomata being closed, the roots modifying their action, or to the bringing into play of some reserve force whose existence we do not ordinarily suspect, is a problem which might well be investigated in our agricultural laboratories.

Although much splendid work has already been done, both at home and abroad, to demonstrate the uses of stomata, there are still problems to be solved ere we can conclude that we know all there is to be known on the subject. It may, perhaps, be as well to indicate to would-be investigators that a splendid bibliography is appended to the work of Professor Maximov, entitled *The Plant in Relation to Water* (Allen and Unwin, 1929). *Hilderic Friend.*

AN ENGLISH GARDENER IN CHILI.

(*Continued from p.* 226.)

The flora of the Chilean seaside naturally includes many species which are found inland and on the neighbouring sand hills, but there are also a fair number which I have not seen elsewhere. Of these, I think the most interesting is a shrubby Crucifer, of which I have only found two plants, although it may be more common in other localities; it forms bushes several feet through and is about three feet high. The flowers closely resemble those of a single Stock, and are white, and an inch across, while the fruits are large, flat and elliptical, about three-quarters-of-an-inch by a quarter-of-an-inch. It may possibly not be native, as there are several doubtful subjects on the coast and some, notably Ricinus, which is one of the commonest plants in some parts, were certainly introduced and have gone wild.

Another example is Eschscholzia californica, which is more at home and more plentiful in some localities than native plants; once its long, woody roots get a good hold, it will withstand any amount of sun and drought; it simply dies back to a small tuft of foliage and starts away again vigorously with the rains.

On the rocks near the sea are many succulent halophytes which I cannot place. Two of these which I believe to be Nolanas, have large, campanulate flowers, blue and white, respectively, with broad, triangular leaves. Another forms curtains over the rocks, with short, grey-green, fleshy leaves, which appear to be terete, but which are actually flattened or fluted on the undersides. This produces short, tubular, white flowers in summer.

---

* Previous studies appeared in our issues of April 13 (p. 279). June 15 (p. 446), Vol. LXXXV; July 13 (p. 30), July 20 (p. 50), July 27 (p. 71); August 17 (p. 130), September 7 (p. 187), September 14 (p. 207), and September 28 (p. 247).

Mesembryanthemum chilense, the only Chilean species, grows all along the coast, particularly on the slopes near the sea, where it receives frequent spray; the leaves are long and triangular, and the stems trail several feet. The flowers are rosy-purple, although a white form is not uncommon, and the fruits, which are edible, have a fleshy pulp not unlike that of Gooseberries.

As regards the marine flora, there are many and diverse forms, the most useful of which is that known as Cochayuyo (literally, sea plant). This plant, Durvillaea utilis, grows on the rocks close in shore, and is cast up in quantities by a rough sea. It is immediately harvested, dried and marketed, and provides a much appreciated national dish.

To return to the cliffs: One of the most common shrubs is Lycium chilense, but a rose-pink-flowered, woody species of Eupatorium covers large areas. In the crevices of the rocks grow many small shrubs and perennial plants, the majority belonging to Compositae. One of the best flowers is a Calandrinia, probably C. grandiflora, with inflorescences two feet high and large, brilliant carmine flowers. The habit and foliage closely resemble that of a Cotyledon or Sempervivum—thick, fleshy stems, branching and bearing rosettes of fleshy, succulent leaves. An Oxalis which also has thick, succulent stems, bears corymbs of primrose-yellow flowers, shown up to advantage by dark green leaves. The latter are shed in summer, and the bare stems roast on the rocks in company with Cereus and Echinocactus. In the spring, these extremely xerophytic plants are wonderfully bright, and form some remarkably effective natural rock gardens.

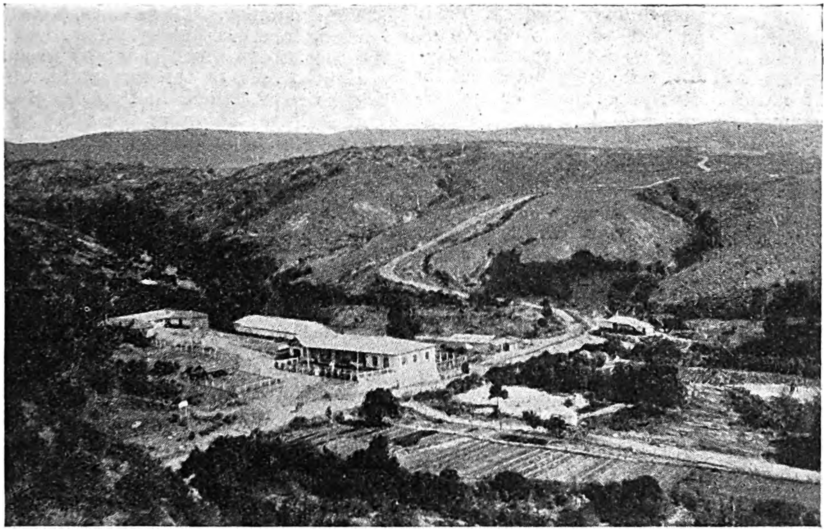

FIG. 133.—AGRICULTURAL SCHOOL, LAGUNA VERDA, NEAR VALPARAISO, CHILI.

Leaving the coast and coming to the slopes of the hills and plateaux of the coast range, we find many different genera and species, some of which are also common, on the long, comparatively level stretch which is the most fertile and productive part of central Chili, lying between the coast range and the Andes.

The surface soil of these hills is chiefly heavy loam with, in parts, clay and gravel, and the slopes, being for the most part uncultivated, for lack of water, are the more interesting from the point of view of the plant hunter. The trees are, with few exceptions, evergreen, with thick, coriaceous leaves; isolated specimens growing in the open form compact and generally very symmetrical trees, in fact, they remind one of the clipped Bays on a large scale.

Three of the most common are known as Peumo, Boldo and Litre. The first, Cryptocarya Peumus, belongs to Laurinae; it has fairly large, dark green, glossy leaves, but very small, insignificant flowers, followed by red, oval fruits, which in size and appearance might be compared to an Acorn; the pulp, which is not plentiful, is edible. The Boldo, Peumus Boldus (syn. Boldia fragrans) is, like the Peumo, comparatively slow-growing, forming a dense mass of foliage; most of the year the plants are dull, heavy-looking trees or bushes, but early in May they are smothered in white inflorescences to which the dark leaves form an effective background. The leaves are highly aromatic and are greatly esteemed by the country people, who infuse them in boiling water to make a drink like tea. Its family is Monimiaceae.

The Litre, Lithraea venenosa, is low-growing and shrubby, but in time makes a stunted, spreading tree. It is of little interest, has small, white flowers, flushed with pink in the buds, followed by quantities of light-coloured fruits, and is best avoided on account of its poisonous properties. On some people, contact with it brings out an ugly and irritating skin eruption. Its family is Anacardiaceae. In these exposed situations none of the three grows more than fifteen feet or twenty feet high, frequently with huge trunks in proportion to their size; all are used extensively for fuel, especially in the form of charcoal.

Belonging to the same family as the Litre and a close relation, although apparently not so resistant to drought, is Schinus latifolius, El Molle. In this the flowers are white, and although small, are borne in great profusion. Another tree, less common but more interesting, is the Quillay, Quillaja Saponaria, the bark of which is rich in saponin and is prepared and sold for cleansing purposes. The flowers are fairly large, but inconspicuous, while the fruits are curious; these are hard, divided into five carpels which, when mature, fold back, dehiscing by both dorsal and ventral sutures and releasing a quantity of small, winged seeds. Belonging to Rosaceae, this tree reaches twenty to thirty feet in height, and generally has several trunks arising from the same root-stock.

Another evergreen of some economic importance is the Lingue, Persea Lingue (Laurinae), which is prized for its yellowish-white wood that is easily worked, and as it stains well is used for imitating more valuable woods. Another species of Persea, not native, is extensively cultivated for its fruits, and called Paltas; this is Persea gratissima and its variety melanocarpa.

Generally, in a more sheltered situation, is found one of the most beautiful of Chilean trees, the Mayten, Maytenus Boaria; this attains a height of fifteen or twenty feet; it has the graceful habit of the Weeping Willow, and deep green foliage, which, incidentally, is used as forage in times of drought. The family Celastraceae is easily recognised by the resemblance of the fruits and flowers to those of the European Euonymus.

An exception to the general rule in that it is deciduous, is the only native Acacia, A. cavenia (A. Farnesiana), well-named Espino. The flowers are large for the genus, golden-yellow, and freely produced; the branches are close-growing and armed with strong thorns. The legume is hard and black, about two inches long, and is indehiscent. It rarely grows more than ten or twelve feet high, but sometimes has a spread of over twenty feet. There are some parts of the country covered entirely and almost exclusively with this species, and in September and October it makes a brilliant picture.

The smaller shrubs vary considerably in different localities; in some places the vegetation is chiefly composed of Berberis Darwinii, Trevoa trinervia, and Colliguaja odorifera. The first of these three is too well-known to require any comment. Trevoa trinervia is a spiny shrub belonging to Rhamnaceae; in habit it is untidy and rambling, and in summer nothing but a tangle of bare brown branches and spines, as it drops its leaves in time of drought. In winter, however, with the first rain, it produces masses of bright green, and in July quantities of close, white inflorescences. Although small individually, collectively the flowers are conspicuous at a considerable distance, the more so as it is one of the earliest species to flower. Colliguaja odorifera is also early-flowering and is an evergreen dioecious shrub with large male catkins. These are green and tinted with varying shades of red and brown, and bear large quantities of yellow pollen; the female flowers are small and appear to consist of little beyond three curling, red styles. When pollenated, these produce green, triangular fruits about half-an-inch long and as much in diameter, triocular, and with (generally) three hard, black seeds. The leaves vary between one inch and one-and-a-half inch long, are coriaceous, simple, elliptical or slightly ovate, having a serrated edge, the teeth of which are brown, giving the shrub a characteristic appearance. It grows about six feet high, and possesses the sticky, white latex so often found in the family Euphorbiaceae. *G. W. Robinson.*

(To be continued.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)
(Continued from p. 251.)

ENGLAND, S.

SURREY.—The fine show of blossom on almost every fruit tree here in the spring has not been followed by an over abundant crop of fruits. The long winter and dry, cold spring, no doubt, had a great deal to do with the deficiency. Apples are not up to average. Among the best bearers this year are Lady Henniker, Lane's Prince Albert, Stirling Castle, Frogmore Prolific, Annie Elizabeth and Bramley's Seedling. The dessert kinds have very light crops. Pears are good on walls, and orchard trees are again well laden, the perry varieties especially so; Peaches and Nectarines are very light. Cherries were poor and Plums are very scarce, although with us Victoria never seems to fail. Raspberries were very plentiful, but were effected by the drought. Strawberries were exceedingly good, but very late. Black Currants and Gooseberries were again well over the average, but Red and White Currants were not plentiful. Figs outside, also Walnuts and Filberts, are bearing good average crops. The soil is very light. *John H. Shipley, Haling Park Gardens, South Croydon.*

——Fruit trees and bushes generally withstood the drought in this district remarkably well, especially considering the nature of the soil, which is a sandy loam on a bed of gravel. Apples and Pears are rather small, due to the lack of moisture. Pears appear to be the crop of the season. Bush fruits were all very good, Black Currants exceptionally so. Strawberries in this district were practically a failure. *O. Maddock, Ham House Gardens, Richmond.*

—— Apples here are almost a failure. Standard trees in the orchards blossomed well but never set fruits. I have a few pyramids that are sheltered from north-east winds which are bearing a few fruits; Allington Pippin, King of the Pippins, Wealthy, Beauty of Bath, Charles Ross and Lane's Prince Albert are the only trees that are carrying crops. Strawberries in this district were almost a failure, although a bed of last autumn-layered plants have given a good crop. Raspberries and Black Currants carried heavy crops, but Red Currants were poor. Peaches have fruited well. Pears are lightly cropped on pyramids, and I have a very heavy crop of Quinces. The soil here is of a very light nature, on sandy subsoil. *N. Fullegar, Eastbury Manor Gardens, nr. Guildford.*

—— Crops of Apples, Pears and Plums are somewhat patchy. Some trees are bearing very well, but others are considerably below the average. The Gooseberries were poor, as they suffered from early drought. Black, Red and White Currants were exceptionally good. Strawberries were abundant and good in size and flavour, in spite of the drought; The Duke, Duchess of York and Sir Joseph Paxton do remarkably well here. Raspberries were also a good crop. The soil here is a rather light loam. *James A. Paice, Copseham, Esher.*

—— Here, Apples, Pears, Plums and Strawberries have produced the poorest crops within memory. Bush fruits, on the other hand, fruited well; Black Currants, Raspberries and Gooseberries especially so, in spite of drought. The soil here is sandy, resting on a subsoil of red sand. *Charles Marchment, Winterfold House Gardens, Cranleigh.*

SUSSEX.—Apples are the outstanding crop of the year. The set is very heavy indeed on nearly all varieties, and the fruits have developed well and are exceptionally clean; scab has been controlled very easily, but sawfly has been rather troublesome. Plums blossomed well, but some varieties were cut by frost. Others set well, but afterwards dropped their fruits badly; Czar and Belle de Lorraine are the best. Pears and dessert Cherries did not set well. Morello Cherries were a full crop. Among bush fruits, Raspberries were over average; Black Currants and Gooseberries, a good average; and Red Currants rather under average. Strawberries lost a lot of their early bloom, but turned out better than was expected. The soil here is mainly Hastings sand. *E. M. Bear, Magham Down, Hailsham.*

—— The exceptional display of bloom on all kinds of Pears was followed by a fine set of clean fruits, quite two-thirds having to be removed. Of Apples, the same cannot be written, for although the amount of bloom produced was much below the average here, a great deal of this was ruined by the late frosts, with the result that we have the lightest crop of Apples that I have seen at Gravetye for the past seventeen years. In the lower ground the Gooseberry and Black Currant crops were ruined by the late frosts, but on higher land excellent crops were produced. The Strawberry disease so prevalent in this district has undermined the constitution of the plants, with the result that both quantity and quality are lacking. Nuts are abundant. Raspberries, mostly of a perpetual or autumn-fruiting character, were, in some instances, seriously damaged by the severe winter frosts; the crop is therefore lighter than usual. *Ernest Markham, Gravetye Manor Gardens, East Grinstead.*

—— The fruit crops here are exceptionally good, having escaped the late spring frosts, through being in close proximity to the coast, and the gardens being sheltered from north and east winds. Peaches, Nectarines and Pears are bearing freely, and thinning of these crops had to be taken in hand early. Apples, Plums and Cherries are average crops, and outdoor Figs good. Strawberries bore an enormous crop of very fine fruits; the plants are free from disease, and of healthy and robust growth. Gooseberries, Raspberries and Red and Black Currants bore heavy crops of large, fine fruits. Owing to the prolonged drought, all fruits had to be watered heavily. *J. J. Thompson, Compton Place Gardens, Eastbourne.*

WILTSHIRE.—Apple crops are very light in this district, but the trees are fairly clean and free from aphis. After the heavy yields of fruits in 1927 and 1928, fruit buds were scarce. This usually occurs with us after two or three years of full crops. Pears bloomed profusely, but there is only an average crop; probably the low rainfall of the district during the early months of the year was the cause of the blossom not setting satisfactorily. Plums are an average crop and very good, Monarch and Victoria being among the best. Cherries, both Sweet and Morello, all carried heavy crops, and Peaches and Nectarines are exceptionally plentiful and good; the trees are very clean and have been very free from blister this year. Apricots are a poor crop as there was hardly any blossom on the trees. Small fruits in all cases were very good, Raspberries in particular, The Devon and Pyne's Royal bearing excellent crops. Strawberries were good in some gardens, but a failure in others, and only where a change of stock has been obtained were the results satisfactory. The soil in this neighbourhood is of a light nature, overlying chalk or gravel. *S. W. Tucker, Longford Castle Gardens, Salisbury.*

ENGLAND, S.W.

DEVONSHIRE.—Apples promised well, but drought has caused a lot of fruit dropping. Gooseberries and Red and Black Currants gave very good crops. Pears are a better crop here than we have had for some years, but Plums dropped badly owing to drought. The soil here is light loam, over shillit subsoil—not very retentive and liable to feel the effects of drought. *Charles F. Mackintosh (Horticultural Department), Seale Hayne Agricultural College, Newton Abbot.*

SOMERSETSHIRE.—With the exception of Apples and Plums, the fruit crops in this district are very satisfactory. Peaches and Nectarines have been plentiful, and Pears are a good medium crop. Raspberries fruited abundantly, especially the variety Lloyd George. Strawberries were plentiful and very fine fruits. Plums are scarce. Black, Red and White Currants carried full crops. Apples are below the average for this district. Apricots and Cherries are above the average. Nuts of all kinds are plentiful. *J. Yandell, Halswell Park Gardens, nr. Bridgwater.*

GLOUCESTERSHIRE.—Many varieties of Apples were frosted at blossoming time, especially Bramley's Seedling. Pear and Plum blossom were also frosted. Raspberries bore an excellent crop of good quality. Black and Red Currants bore good crops. Many of the canes of Loganberries were killed, with the result that the crop on these is only moderate. Early blossoms of Strawberries were frosted, and plants and fruits suffered from drought, except de-blossomed maidens for runners. *J. G. Maynard, Pomologist, Research Station, Long Ashton, Bristol.*

—— We had a very fine show of blossom on all fruits, especially Pears and Apples. The former set well, but when the fruits were about the size of Peas, by far the greater number were shed. This was owing chiefly to the prolonged drought. Much the same remarks apply to Apples, and a lot are falling now, but we hope to have enough left for an average crop. Small fruits were better than we expected, Gooseberries and Black Currants being very good both in quantity and quality. The weather has been very trying for all crops. The soil here is heavy clay. *John Ettle, 201, Henleaze Road, Westbury-on-Trym, Bristol.*

—— Fruit trees generally show little signs of the severe winter, although here and there an Apple tree was injured in growth. Almost all kinds of fruits blossomed well, the principal exception being Apricots. In most cases the fruits set well, in spite of the almost nightly frosts, but crops on Apples Beauty of Bath and Worcester Pearmain are rather light. Red Spider has been troublesome on trees of Lane's Prince Albert and Langley Pippin. Peaches and Nectarines carried better crops than they have for several years, and were wonderfully free from leaf-curl. *S. W. Dance, Williamstrip Gardens, Coln St. Aldwyns, Cirencester.*

(*To be continued.*)

FRUIT GARDEN.

ROOT THINNING AND PRUNING.

ONE of the essential conditions in the successful cultivation of fruit trees in pots is that they must be overhauled periodically, and their roots thinned and pruned. This practice, however, is not general with fruit trees grown out-of-doors against walls or on fences, on the restrictive system, and yet the conditions are very similar. These trees, whether they be cordons, fans, or espaliers, are worked on restricting root-stocks which generally produce, within a limited area of the tree stem, quantities of fibrous roots, which in time become worn out and useless. Thinning the roots of such trees is quite as important as thinning the roots of fruit trees in pots.

We frequently come across trees, however, which obviously require root pruning, which is distinct from root thinning. Peaches, Apricots and Plums, in particular, may be found in two different conditions, either producing too much wood and very few fruits, or starved, stunted and bearing inferior fruits. In the first case the tree roots have, more or less, got out of control. They have, perhaps, entered the subsoil of some well-manured border immediately in front, and in their case root-pruning is the surest method to adopt to bring the trees into a fruiting state.

With the stunted tree, however, the case is quite different. When the surface soil about the tree is removed, a tangled mat of roots all struggling for existence will, invariably, be found. Most of these roots are of little use to the tree. They should be thinned, the oldest being removed and the cleanest and most promising retained. A trench, eighteen inches wide and the same in depth, should be made four or five feet away from the stem. Work inwards with a fork to the base of the tree, removing so much of the old, exhausted soil as possible until most of the roots are exposed. When the thinning and pruning is completed, the trench should be refilled with a good nourishing compost made up of loam, a little lime-rubble, and wood ash, and a good sprinkling of bone-meal. Make the soil firm about the roots, working it in among the fibres, and bringing these nearer the surface. A little well-rotted farmyard manure added to the top three or four inches of soil will be found advantageous for encouraging root action, and for the retention of moisture next summer. The best time to carry out this work is during October when the leaves are about to fall. There is then some warmth in the soil. Wounds heal over quickly, and new roots are pushed out at once, which are more capable than the old and matted roots of obtaining nutritive matter from the soil. A good watering should be given to settle the soil about the roots, and repeated in a few days, especially to wall fruit trees, if the weather is dry.

When trees make too much growth, it is certain they will not form fruit buds, nor will the wood ripen properly. If the trees are not too large they may be lifted carefully, the roots shortened, preserving most of the fibrous ones, and the trees replanted, working into the soil plenty of lime-rubble and wood ash, and making the soil very firm by treading or ramming. *H. H. C.*

GARDEN MANURES FOR OCTOBER.

Most growers recognise in a general way the necessity of making periodical applications of phosphatic fertilisers to make good the loss which must inevitably result from continuous cropping; moreover, on certain types of soil particular crops, such as Potatos, Turnips, Peas and Beans, and some fruit crops, are particularly responsive to their application.

In the method of application of this important element a wide range of choice is offered as there are so many varieties of phosphatic fertilisers that it is sometimes difficult to select the type most suitable for a certain soil condition or for a particular crop, but, broadly, these fertilisers may be divided into two main groups, (a) those soluble in water, and (b) those insoluble in water; and it is from the latter group that the type should be chosen for use at this season of declining activity in plant growth.

The three chief types of insoluble phosphates in this group are bone-meal, basic slag and rock phosphates, and while certain advantages accrue from the use of bone-meal because of its organic origin, its extensive use in the preparation of feeding meals makes it too expensive for use as a general fertiliser. A good sample contains nearly fifty per cent. of phosphate and from four to four-and-a-half per cent. of nitrogen, but it is even slower in action than the best grades of basic slag.

Basic slag contains two fertilising ingredients, phosphoric acid and lime, the percentages of which vary according to the nature and quantity of the materials used for removing the phosphorus from pig iron in the process of steel manufacture. Owing to the form of combination of the phosphoric acid, it is insoluble in water but more or less soluble in weak acids, and the action of acid excretions from the roots of plants produces a solution in the soil water, which, being similar to that of weak organic acids, is easily capable of dissolving a greater or less proportion of the phosphoric acid contained in the various basic slags. A certain proportion of the phosphoric acid is also dissolved by water containing carbonic and ulmic acids, and is thus conveyed to the feeding roots. The degree of effectiveness of any basic slag depends, therefore, upon the percentage of its phosphoric acid which is easily soluble in weak acids, and is consequently assimilable by the roots of plants. As different forms of basic slags show material differences in solubility, the general standard adopted for measuring its effectiveness in the soil is its solubility in a two per cent. solution of citric acid, therefore in purchasing a precise guarantee of citric-soluble phosphates in the sample offered is a better guide to its probable effectiveness in the soil than a simple statement of its total percentage of phosphate.

An advantage in the use of basic slag is that there is no fear of loss through washing out by drainage; the phosphoric acid not taken up in the first year remains in the soil in undiminished availability for the use of succeeding crops, and good effects from its application have in some cases been noted for several subsequent years. Further, the lime contained in basic slag is itself of considerable value and supplies what is often a much needed base, and its effect in bringing the soil potash into solution and in promoting oxidation of the nitrogenous reserves in the soil is sometimes very marked.

Rock phosphates, particularly the relatively soft north African rock, have a higher phosphate content than any other type of phosphatic fertiliser, and samples containing over eighty per cent. of phosphate of lime are not uncommon; moreover, they are the cheapest phosphatic fertilisers available per unit of phosphate. Probably their use is more extended in the field than in the garden, but they may be used with confidence as a substitute for the best basic slags and, generally, give as good results. Like basic slag, they are slow in action, and their effectiveness depends largely on the fineness of grinding. They are usually ground so that eighty per cent. will pass through a sieve with 10,000 holes to the square inch, but some samples are ground even finer than this, and there is some evidence to show that the better results obtained from the use of this finer material more than justifies the extra cost of grinding.

It cannot be too much emphasised that in the use of all these fertilisers which are insoluble in water, thorough incorporation with the soil is an essential factor in successful treatment. Water-soluble fertilisers may be carried in solution by the soil water to the feeding roots of the plant and become absorbed, but the insoluble ingredients must be widely spread through the rooting area so that the weak acids in the soil or the acid exuded by the roots can dissolve them and make them ready for absorption. *W. Auton.*

HOME CORRESPONDENCE.

National Carnation and Picotee Society.—The information supplied to your readers on p. 210, by Mr. A. E. Amos, Hon. Secretary of the National Border Carnation and Picotee Society (Southern Section), instead of clearing any doubts at present existing in the minds of prospective members, is little less than a deliberate and unprovoked charge of misrepresentation and misappropriation against the Northern Society. Evidence supports the assertion that the only society entitled to use the title claimed by your correspondent has long been defunct; yet it is interesting to add that it was a Northern Society, operating from Manchester, and formed in 1874. During its period of existence, the Southern Society, founded in 1877, was "an ordinary affiliated society." This is merely history of yesterday, and is of little moment, but the Southern body cannot conceivably offer any advantages over the Northern Society for a resident of the Midlands or North. The latter Society lays no claim to cater better for interested gardeners out of its territory, but its members justifiably take exception to a cheap advertisement at the expense of their interests. *John A. Hewitt, Hon. Treasurer, Northern Section, Rock Street, Tilsmoor, Sheffield.*

Vegetables at Burford, Surrey.—In spite of the drought, vegetables have never been better than they have been this season at Burford. The Cabbages are very good indeed, and we were very pleased with the behaviour of that trio of spring Cabbages, Sutton's Harbinger, Sutton's Flower of Spring and Sutton's April. At the present time Summer Drumhead is a good Cabbage, but is surpassed by Kinderkopf, a marvellous, solid, green ball the size of a child's head, by Winningstadt, and by the two quintal Cabbages which are named after Auvergne and Alsace. Potatos have been uniformly good, although somewhat small. For all-round purposes, nothing beats Majestic; Red King, which we are trying for the first time, is a handsome Potato but, personally, I do not care for its flavour. In Cauliflowers, the Erfurt Market variety has been a great success; on the other hand I do not think that the much lauded Roscoff is going to do well here. This year has suited Haricot Beans very well indeed, and they promise to shell out well, both as regards colour and size. Some people think that any French Bean can be used for Haricots, but this is a complete mistake, for the tender-skinned Flageolet is the result of many years' breeding and selection. We have been pleased to find an increasing interest taken in out-of-the-way vegetables, and we have had many visits from head gardeners whose employers are interested in these vegetables. Mexican Tree Spinach is now nearly ten feet high, and is the only Spinach we are picking at the present time. The first crop of Fennel showed a tendency to bolt, but the second was excellent and produced fine hearts. We have never had so many Aubergines and Peppers; they are planted out in frames, the lights being taken off permanently towards the end of May. In Aubergines there is nothing to beat Black Beauty, and of Sweet Peppers Glory is the one to grow. Aralia raised from seeds has made immense growth and should force very well in the winter. Canteloup Melons planted out in unheated frames have cropped well and carry six to eight fruits to the plant. It is quite unnecessary to fertilise them by hand, as fertilisation is done by the bees. Cape Gooseberries are producing a marvellous crop and we hope to exhibit them at the Fruit and Vegetable Show. *William Lawrence.*

Insects that Fertilise Pansies.—It is well-known that garden Pansies, including those that are popularly named Violas, do not come true from seeds, but little is stated about insect agency, much less the actual insects that visit the flowers. During seven years no species or variety of Viola had been planted in our garden, but about two years ago a degenerate Pansy appeared, and since then hundreds of plants and thousands of flowers have been produced, and every one of them came true to colour. These flowers must have been selfed, seeing that no other was in the same or immediate gardens. Many years ago, I observed that the Silver-Y Moth (Plusia gamma) was very industrious in visiting the flowers of garden Violas during the dusk of the evening, and passing from one colour to another indiscriminately. I had considerable trouble in excluding this moth by fixing gummed paper over the entrance to the nectary of varieties that I had been crossing, for the paper sometimes got pushed aside and my work was frustrated. Butterflies occasionally visited the flowers during the day, but they were clumsy plunderers owing to the irregular structure of the flowers. Two seasons ago, I sowed seeds of the wild Viola Pesneaui (V. rothomagensis), and this year had ample evidence that hive and humble bees, chiefly Bombus hortorum, were quite expert in probing the flowers of the above species or variety of Viola lutea. Seedlings have sprung up in abundance and it will be interesting to know whether or not the flowers have been crossed with the degenerate garden Pansy. *J. F.*

Identification of Fruits.—I should be very much obliged if you could draw the attention of the readers of your paper to the desirability of giving full information when fruits are sent in for naming or identification. We invariably ask when sending in fruits, that the following regulations should be conformed with:—Of fruits, send at least three perfect specimens of a variety. Do not send until the fruits are mature, and then choose specimens representative of the particular variety. Avoid sending bruised, diseased or abnormal fruits. Include with each variety a typical shoot with foliage. Number each variety, preferably in Roman figures, by marking the skin with a hard pencil and keep a record of the tree from which it is gathered. Labels are often displaced during transit. Wrap each fruit in paper and pack it carefully and securely in wood-wool or similar material. Flimsy cardboard boxes are usually crushed in the post, while scented soap boxes taint the fruits and obscure the characteristic flavour. Give all the information you can respecting the age of the trees and how they are grown, *e.g.*, indoors or out, as cordons, bushes or standards, etc. I think you will agree with me that if a little more care by enquirers was taken, not only this Society, but many other Societies or persons asked to name or identify fruits, would be very much facilitated. *F. R. Durham, Secretary, Royal Horticultural Society, Westminster.*

Cotoneaster frigida var. fructu-luteo.—The following record of an experience in breeding this shrub may be of interest to your readers. The variety differs from the type only in the colour of its fruits, which is yellowish or creamy-white instead of bright red. In September, 1920, when visiting Stevenstone, North Devon, I obtained fruits of this variety from a single plant growing in the grounds there (Mr. Bean refers to this Stevenstone specimen in his *Trees and Shrubs Hardy in the British Isles*). From the seeds so collected, thirteen plants were raised at Roath Park in 1921, and these (growing together in a nursery row) produced flowers and fruits for the first time in 1925. Without exception, the fruits proved to be of the same bright red colour as in the type. In turn, seeds from these were sown in 1926, and nineteen of the plants so raised have flowered and fruited for the first time this season. In ten of these plants the fruits are again red, but the other nine bear the yellow fruits of the fructo-luteo grand-parent. Incidentally, it may be mentioned that in these yellow-fruited plants the foliage is of a distinctly lighter shade of green than in the type. To explain these results, it would seem necessary to assume that individual plants of C. frigida are self-sterile (which is not improbable), and that the flowers of the solitary Stevenstone yellow-fruited plant were, in 1920, fertilised by pollen from a plant of the red-fruited type growing in the vicinity. On this assumption, red would appear to be dominant over yellow. Further, to test the recessiveness of yellow, I intend next year to cross the nine yellow-fruited plants among themselves, in the expectation of raising a batch of yellow-fruited seedlings, and yellow only. *A. A. Pettigrew, Cardiff.*

Meconopsis Baileyi.—In *The Gardeners' Chronicle* for July 13, Mr. Jonathan Fiona refers to this plant as "generally supposed to have been discovered some few miles from Gangtok in the Tibetan Alps by Major Bailey." "Generally supposed," of course, commits no one, except Mr. Fiona. The facts are easily ascertained by anyone who takes the trouble to look them up—*not* in *The English Rock Garden*, published six or seven years before Meconopsis Baileyi was seen in England. Gangtok is not in the "Tibetan Alps"—wherever they may be—but is the capital of Sikkim. From Gangtok to the home of M. Baileyi in Tibet is 300 miles in an air line; but since one cannot yet fly over the Himalayas, it would give a better idea of the country and mountains to state that it is a month's hard marching by the shortest route. Surely "some few miles" is a misleading understatement—except perhaps in the American idiom! *F. K. W.*

COLONIAL CORRESPONDENCE.

DIDYMOCARPUS.

This interesting family of the Natural Order Gesneraceae is very common in Malaya. Ridley, in the *Flora of the Malay Peninsula*, mentions fifty-six species and about ten varieties. The flowers are disposed in terminal panicles or in a cyme of one or more flowers. The corolla is funnel-shaped, white, blue, yellow, purple, white streaked with violet and other beautiful shades. They are found growing in dense jungle from sea-level to 6,000 feet altitude, but they prefer the mountain forests, especially near running water.

Unfortunately, they are difficult subjects to cultivate, and a position in a shady part of the garden is essential. Some of the species, however, make excellent pot plants and may be successfully grown in the Fern house or interplanted with Ferns.

The following species are found in the Larut Hills:—D. crinita, a dwarf plant with woody stems about six inches tall; the leaves are lanceolate, pubescent above and below; corolla trumpet-shaped, pale blue, often nearly white or white with blue lobes. D. malayana is found at low elevations; it has short stems and firm, ovate leaves, the corolla is bright yellow, about two inches long and rather narrow at the base. It is known locally as the Malay Cowslip. D. sulphurea is a shrubby, pubescent semi-climber with deep green leaves which are purple and hairy beneath, and are arranged in unequal pairs, while some are large and others only half-an-inch long; the corolla is funnel-shaped, nearly an inch long, with the lower lip longest, pure yellow; a very distinct plant. D. flava is a shrubby plant nearly four feet tall, leaves lanceolate, acute, very hairy, about four inches long and one-and-a-half-inch wide; the flowers, which are rich yellow, are borne on tomentose peduncles in clusters of four or five together.

Other species are D. citrina, D. violacea and D. hispida. The last-named is very common on Maxwell's Hill, Malaya; it has funnel-shaped flowers which are white, with violet streaks in the mouth of the tube.

A compost of peat or leaf-mould, loam and a little silver sand, is suitable for them, while propagation is effected by cuttings. *F. S. Banfield, F.L.S., Malaya.*

SOCIETIES.

ABERGAVENNY SHOW.

This show is really four in one, and it was first established as a Horse Show in 1868. Since then other sections have been added, including the horticultural one. The show was held in Bailey Park, early in September; the weather was fine and the attendance good.

The horticultural section fully maintained its high reputation, the whole being admirably organised by the Secretary, Mr. H. J. Rice. There was an extraordinarily fine lot of flowers, while the large Onions and collections of vegetables attracted considerable attention. The principal class in the open section is that for trade exhibits, to occupy a space twenty feet by four feet, and in this there were five exhibits. These were of a high standard, and the judges had some difficulty in making the awards. The first prize and the Vaughan-Morgan Shield were awarded to Messrs. S. Treseder and Son, Cardiff, who staged an artistic group of Dahlias, Roses, Chrysanthemums and Gladioli; second, Messrs. W. Treseder, Ltd., Cardiff, whose display contained a meritorious lot of Dahlias; and third, Messrs. Fraser and Brown, Abergavenny, with a miscellaneous collection of Lilies, Gladioli, etc.

For a collection of Roses arranged for general effect, to occupy a space ten feet by four feet, the King's Acre Nurseries were first. Theirs was a fine effort, the whole group being most artistically arranged. There were excellent pillars of Shot Silk, Madame Butterfly, Betty Uprichard, the beautiful Lady Inchiquin and Mabel Morse, while the front contained several good Polyantha varieties, notably Edith Cavell, Marshal Foch and Elsie Poulsen. The second prize was gained by Messrs. Barham, Bessaleg, Newport, whose best varieties were Lady Inchiquin, Margaret McGredy and Elizabeth of York.

Herbaceous flowers were quite a feature, the first prize for nine distinct varieties, including bulbous plants, being secured by Col. Herbert, Abergavenny, whose best vases were of Senecio Clivorum and Physostegia virginianum.

Annuals were well displayed, also Asters and Dahlias, the dry season being responsible for the first rate blooms of the former.

All the vegetables classes were well filled, and in the open section for ten distinct kinds, Mr. T. Bowen, Aberaman, secured the Challenge Cup and first prize for finely grown produce, his Onions, Celery and Cauliflowers being especially good; Mr. F. Jenkins, Aberdare, was second.

In the amateurs' class for a collection of vegetables, competition was more keen, only six distinct kinds being required. Mr. A. P. Thomas, Abergavenny, secured the premier honours and the Challenge Cup with excellent produce, and he had fine Beans, Cauliflowers and Celery; Mr. J. Berry was second, and Mr. W. Price, third. Potatos were well shown, and the Silver Medal and first prize for a single dish were won by Mr. T. Howard James, Magor; while for a collection of six varieties, the first prize and Silver Medal were gained by Mr. F. S. Rogers, Caerphilly, with Mr. F. Bowen, second. Onions were exceptionally good, and here Mr. F. Bowen excelled in both classes—for winter and spring varieties, respectively.

This show is also remarkable for the display of fruits. For a collection of twelve dishes of hardy fruits (Peaches and Nectarines excluded), Miss Solly Flood, Crickhowell, won the Challenge Cup and first prize with fruits remarkable for their high culture and splendid finish, the Cherries, Plums, Currants and Apricots being noteworthy. Lord Treowen was second, and Miss P. Marshall, third. The Hon. Mrs. Bevan, Monmouth, was first for Grapes, and Miss Solly Flood led for six Peaches.

Non-competitive groups were also a feature of the show, and Gold Medals were awarded to the King's Acre Nurseries, for pot fruit trees; Messrs. H. Townsend and Sons, for a miscellaneous group; and Messrs. Pitt and Son, for a similar display and various floral designs. Mr. W. E. Pope, Abergavenny, secured a Silver-gilt Medal for a group of seasonable subjects, nicely arranged. Many educational exhibits were staged in a special marquee by the Monmouthshire Agricultural Institute.

CHESHIRE COMMERCIAL FRUIT SHOW.

This show was held in conjunction with the Middlewich Show in mid-September, and a special tent was devoted to it.

At the end of the marquee the Cheshire School of Agriculture had a grading machine and box-nailing press, and demonstrations were given in grading and packing. One side of the marquee was taken up with the Cheshire School of Agriculture Horticultural Department's educational exhibit. The result of the tar-distillate spraying trials were explained by means of charts and piles of Apples demonstrating increased weights from certain sprayed plots.

The lime-sulphur trial plots for scab control also had a place, and charts showing weights of fruits from sprayed plots showed that where tar distillate alone was used it seemed to increase scab, and there was more scab on these plots than on the control plots, both in the case of Worcester Pearmain and Bismarck. Manuring also was dealt with, and samples of potash starvation and nitrogen starvation were on view, together with the manures necessary to prevent such conditions. There was also a very interesting collection of insect pests and fungus diseases found in Cheshire attacking Apple and Pear trees.

On the other side of the marquee there were three trade groups. Messrs. Murphy and Son had an excellent exhibit showing the various products they sell, and a very effective feature was a Mortegg-sprayed branch and an unsprayed branch from the orchards of Mr. C. Derbyshire, Middlewich. The Warwick Saw Mills had a stand displaying Apple and Pear boxes, and Messrs. Booseys had a very good collection of Apples and Pears on view, together with maiden and two-year-old Apple and Pear trees.

There were eight competitive classes. For two half-boxes of Apples, any early dessert variety, Mr. C. Goodwin, Holmes Chapel, was first; and Mr. H. C. Croome, Guilden Sutton, Chester, second, both showing Worcester Pearmain. Mr. William Platt, Leftwich, Nortwich, was first for two half-boxes of a late dessert variety; second, Mr. H. C. Croome; while for two boxes of Bramley's Seedling, Mr. H. C. Croome led, and Mr. C. Goodwin was second. For two boxes of Lane's Prince Albert, first place was taken by Mr. H. C. Croome; second, Mr. William Platt; and Mr. Croome also led for two boxes of Newton Wonder.

The first prize for two boxes of Lord Derby was secured by Mr. William Bibby, London Road, Frodsham; second, Mr. C. Goodwin. Mr. H. C. Croome, with Bismarck, showed the best two boxes of cooking Apples, any variety, while in the class for two half-boxes of dessert Pears, first place was taken by Mr. C. Derbyshire, Mr. H. C. Croome securing the second prize.

BANFFSHIRE FIELD CLUB.

"One of the most interesting addresses ever delivered in that hall" aptly describes the lecture on the Begonia, given by Mr. John G. White, of the Aberlour Orphanage, Banffshire, before the members of the Banffshire Field Club. For well nigh three decades, Mr. White has devoted much of his leisure to the cultivation of the Begonia, and his failures and successes during that period were delightfully set forth in the course of his address.

At the outset, Mr. White stated it was really marvellous to see the Begonias of to-day, in view of the very few species from which they had sprung. In 1865, a collector, Pearce, travelling in Bolivia, sent home the first tuberous-rooted Begonia. From species discovered in Bolivia, the whole of the tuberous Begonias had sprung, and it was simply due to hybridisation, and man's careful crossing of the different varieties, they had to attribute the exquisite specimens seen to-day. As an instance of the value which was placed upon the plant, Mr. White told the story of the English grower who kept to himself for seven years the beautiful variety Lady Cromer he had produced, then sold it at 30s. per tuber, and netted about £700 from it. There has been a great improvement effected since the advent of Lady Cromer, and he regarded Lady Ann as one of the best to-day.

At this point, Mr. White exhibited a specimen of this variety on which were blooms seven inches across. Proceeding, Mr. White characterised the tuberous Begonia as the best decorative plant for the greenhouse during summer. For bedding out, Begonias were extraordinarily good, and for this purpose the moist climate of the north of Scotland suited them admirably. While not very suitable for cut flowers, they were very useful for floating in bowls. As basket plants, tuberous Begonias were unsurpassed. This season he had seen a magnificent plant grown in a hanging basket by a butcher. It had no fewer than 175 blooms on the one plant, which was of the Mrs. Bilkey variety.

Coming then to deal with his personal experiments, Mr. White confessed that to him the most interesting thing in the growing of Begonias was to secure perfume, and then he told his listeners of some of the successes and disappointments during twenty-three years experimenting towards that end. He started producing sweetly-scented single blooms from the fragrant Bolivian plant and obtained a great variety of scent—Cinnamon, Peppermint, honey, and even so strong a scent as that of Attar of Roses. The perfume was strongest in the morning; in the evening the plant was quite scentless. It was in attempting to obtain scent in the beautiful double Begonia he met with difficulty. It was not until February 26, 1907, that he got what he wanted. Out of a hundred seedlings raised, there bloomed three really good doubles, two slightly scented, the other a gem in size, colour, shape and sweetness, a counterpart, in fact, of the seed parent with the addition of perfume. He named it Double Pink Sweet-Scented. He did not claim to have raised the Sweet-scented Begonia, but he did claim in a humble way to have raised the first large-flowered, double, sweetly-scented Begonia. Nature had played all sorts of tricks with his endeavours. The result of his work in trying to get perfumed doubles was but two varieties. The first he secured, as noted, in February, 1907, and the second in 1925, and that being the year of the Aberlour Orphanage Jubilee, he called it Aberlour Jubilee.

Concluding his address, Mr. White reminded his hearers of the present mechanical age, when everything seemed to be subservient to mechanism, and said he felt sure that in years to come, in the period of robot-like figures, people would surely turn to the garden for recreation, for the garden was "the purest of human pleasures."

The Rev. Dr. Bruce, who deputised for Sheriff More, the President of the Club, in moving a vote of thanks to Mr. White, said Aberlour was becoming a centre of botanical interest, but as units they, the members of the Club, would try to follow the advice that had been given them by Mr. White, who had delivered one of the most interesting addresses ever heard in that hall. Hearty applause endorsed and carried the motion.

GLASGOW AND WEST OF SCOTLAND.

The winter session of monthly evening lectures was inaugurated on September 25, when Mr. John Cowan, Doonholm Gardens, Ayr, described the methods of cultivation which he followed in the production of vegetables for exhibition.

He regarded the preparation of the ground as one of the most important factors towards success, and this work should be done in early winter. All the ground occupied by prize vegetables at Doonholm was trenched at least two spits deep. To those with shallow or sandy soil he did not hold out much hope of success. Next to deep cultivation, good manuring was of importance. Certain varieties of vegetables, such as Carrots, Beetroots and Parsnips, could be grown quite successfully without the aid of farmyard manure. These he grew with a little artificial manure mixed in the soil and put into the holes bored for all tap-rooted vegetables, but Leeks, Celery, Peas, Onions and the various members of the Brassica family required good farmyard manures.

Mr. Cowan then proceeded to discuss in detail the culture of the various subjects which comprised a vegetable collection as staged at a show, viz., Leek, Celery, Carrot, Beetroot, Parsnip, Peas, Cauliflower, Potato, Shallot, French Beans and Parsley. Some discussion followed, and at the close the lecturer was accorded a hearty vote of thanks.

ROYAL HORTICULTURAL.

October 2 and 3.—The second of the series of Autumn Shows contained a great variety of interesting exhibits. The new Horticultural Hall was filled almost solely with the exhibits of "Ornamental Trees and Shrubs," for which the show was chiefly arranged. The general effect was good. The groups were lightly and attractively arranged, and while the brilliant foliage colour usually associated with autumn was on this occasion lacking, the many fruiting trees and shrubs were very showy. The old hall was devoted chiefly to exhibits of hardy border flowers, somewhat similar to those we saw at the first autumn show; but on the present occasion, the graceful stems of Michaelmas Daisies and the general collections of border flowers were arranged with so much taste and skill as to make a delightful picture. Dahlias and Roses were also shown in abundance in the old hall where, we were pleased to find, space had been spared for two meritorious collections of Orchids. The Orchid Committee recommended two Awards of Merit to novelties. Floral novelties were again rather disappointing, though of more interest and value than last week. Four Awards of Merit were recommended to novelties, although none could be considered of outstanding importance. The Joint Dahlia Committee met and made their usual somewhat lavish selection of novelties for trial at Wisley There were several excellent collections of growing and gathered hardy fruits, but the Fruit and Vegetable Committee had little to occupy its attention.

Orchid Committee.

Present: Mr. Frederick J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Sec.), Prince Shimadzu, Mr. Fred K. Sander, Mr. J. Wilson Potter, Mr. A. Dye, Mr. T. Armstrong, Mr. Charles H. Curtis and Mr. J. E. Shill.

AWARDS OF MERIT.

Brasso-Laelio-Cattleya Heliolata (*Cattleya Heliodor* × *Brasso-Laelio-Cattleya maculata*).—In this lovely hybrid the flowers are of beautiful texture, all the segments presenting a smoothness seldom seen. The sepals and petals are primrose-yellow with a slightly deeper yellow suffusion in the centre. The rounded, fringed lip is of similar colour, with a large central area of deep, almost orange-yellow. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Cattleya Helioglow (*C. Golden Glow* × *C. Heliodor*).—A somewhat small but brilliantly-coloured hybrid of pleasing form and golden-orange colour, with a deeper shade over the larger part of the flattish, daintily fringed lip. Shown by Baron Bruno Schröder.

GROUPS, ETC.

In the old hall, Messrs. Sanders staged a group that contained a number of good examples of Odontoglossum grande, various Laelio-Cattleyas, Cattleya Hardyana var. alba, Vanda coerulea, Coelogyne Moorei, V. teres and such quaint subjects as Cycnoches Loddigesii, one with two spikes and four expanded flowers, and one with a spike of a dozen flowers; Brassia brachiata and the tiny-flowered Stigmatostalix radicans.

Messrs. Stuart Low and Co. had a bright display wherein Cattleya labiata was well shown, together with Laelio-Cattleya Mrs. Medo, Brasso-Laelio-Cattleya Oriflamme, of light yellow colour; Oncidium varicosum var. Rogersii, Arachnanthe Clarkei, Vanda Stangeana, of brownish hue; the rare, small, but beautiful Phalaenopsis Esmeralda, with Miltonia Clowesii, and M. spectabilis var. Moreliana.

Robert Paterson, Esq. (gr. Mr. Merry), showed a fine plant of Cattleya Profusion, Paterson's variety, with five big blooms on one spike. This was of lighter colour than usual, with a pair of white blotches towards the base of the purple lip. Gus Meyer, Esq. (gr. Mr. Cottam), Woldingham, showed two species of Mormodes provisionally named M. Buccinator and M. luxatum.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mr. E. R. Janes, Mr. James B. Riding, Mr. J. T. West, Mr. Donald Allan, Mr. A. E. Vasey, Mr. C. F. Langdon, Mr. G. W. Leak, Mr. D. B. Crane, Mr. R. Findlay, Mr. Charles E. Pearson, Major George Churcher, Rev. H. Rollo Meyer, Mr. W. B. Gingell, Mr. M. C. Allwood, Mr. William Howe and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair) Mr. E. A. Bowles, Mr. G. Reuthe, Mr. F. G. Preston, Mr. C. Hiatt Baker, Lady Beatrix Stanley, Mr. L. R. Russell, Mr. R. C. Notcutt, Mr. A. Bedford, Mr. Gerald W. E. Loder, Mr. G. Yeld, Sir William Lawrence, Bt., Mr. T. W. Taylor, Mr. E. H. Wilding, Mr. Eric Marsden-Jones, and Mr. N. K. Gould, Secretary.

AWARDS OF MERIT.

Cornus Mas.—The award to this well-known hardy spring-flowering shrub was given on account of its showy bright red fruits which were borne in abundance on the branches. Shown by the Director, Botanic Gardens, Cambridge.

Ceanothus Autumn Blue.—This vigorous, bushy shrub is stated to have been derived by crossing C. thyrsiflorus with C. Indigo. In general habit the new variety is much like the former species, but shows the inflorescence of the latter in the longer-stemmed and more graceful panicles of deep sky-blue flowers. We were informed that the shrub is quite hardy. Shown by Messrs. Burkwood and Skipwith.

Chrysanthemum Lido.—A shapely market, Japanese variety of golden-bronze colour.

Chrysanthemum Mrs. Sarah Knight.—A larger, flatter flower. The mauve-flushed florets are broad, and the spathulate tips incurve slightly. Both varieties were shown by Mr. H. Shoesmith, junr.

Joint Dahlia Committee.

Present: Mr. H. B. May (in the chair), Mr. J. F. McLeod, Mr. A. Turner, Mr. D. Campbell, Mr. J. B. Riding, Mr. J. T. West, Mr. J. Emberson, Mr. A. E. Vasey and Mr. D. B. Crane.

FOR TRIAL AT WISLEY.

The following new Dahlias were selected by this Committee to be included in the Wisley Dahlia trials.

Phyllis Wheaton.—A charming miniature Paeony-flowered sort with waved, bright rose-pink petals, cream at the base. Shown by Messrs. J. Cheal and Sons, as also were the following.

Bognor Star.—An attractive flower, rich rose-pink, shaded old gold.

Felbridge Star.—Another bright Star Dahlia, golden-yellow, overlayed with orange.

Aurora.—A pale terra-cotta miniature Paeony-flowered Dahlia of good form. Shown by Messrs Wm. Wood and Son.

Albion.—An attractive, pale cream, Paeony-flowered sort. Shown, with the following, by Messrs. Burrell and Co.

Edna.—Of the same type as the above, with deep rose-coloured petals tipped with white.

Cedric.—A deep velvety-crimson Paeony-flowered Dahlia of very compact form, with reflexed, curled petals.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. J. Cheal, Mr. W. H. Divers, Mr. F. Bostock, Mr. J. C. Allgrove, Mr. E. A. Laxton, Mr. G. Kelf, Mr. J. Wilson, Mr. R. H. Hall, Mr. A, Poupart, Mr. F. Jordan and Mr. A. N. Rawes, Secretary.

No novelties of note were shown before this Committee, although many fruits were received for naming.

Awards by the Council.

Gold Medals.—To Mr. G. Reuthe, for shrubs; and to Mr. J. C. Allgrove, for fruits and fruit trees.

Silver-gilt Hogg Medal.—To Messrs. G. Bunyard and Co., for fruits.

Silver-gilt Flora Medal.—To Messrs. J. Cheal and Sons, Ltd., for trees and shrubs.

Silver-gilt Banksian Medals.—To Messrs. Alex. Dickson and Sons, Ltd., for Roses; Messrs. Maxwell and Beale, for Heaths; Mr. R. C. Notcutt, for trees and shrubs; Messrs. D. Prior and Son, Ltd., for Roses; Mr. J. B. Riding, for Dahlias; and to Messrs. R. Wallace and Co., Ltd., for trees and shrubs.

Silver Hogg Medal.—To Messrs. Laxton Bros., for fruits and fruit trees.

Silver Flora Medals.—To Mr. T. Bones, for Michaelmas Daisies; Messrs. Ben. R. Cant and Sons, Ltd., for Roses; Messrs. Dobbie and Co., Ltd., for Gladioli; The Donard Nursery Co., for shrubs; Messrs. Fletcher Bros., for Conifers and shrubs; the Gayborder Nurseries, for Michaelmas Daisies; Messrs. Robert Green, Ltd., for Bay and Box trees; Messrs. Hillier and Sons, for trees and shrubs; Messrs. G. Jackman and Son, for Clematises; Messrs. Jarman and Co., for Dahlias; Messrs. B. Ladhams, Ltd., for shrubs and herbaceous plants; Messrs. L. R. Russell, Ltd., for Clematises and other shrubs; Messrs. T. Smith and Son, for trees and shrubs; Messrs. D. Stewart and Son, Ltd., for trees, shrubs and Conifers; Messrs. Sanders, for Orchids; Messrs. R. Veitch and Son, for trees and shrubs; Messrs. J. Waterer, Sons and Crisp, Ltd., for trees and shrubs; Mr. W. Wells, junr., for Michaelmas Daisies; and to Messrs. Wm. Wood and Son, Ltd., for trees and shrubs.

Silver Banksian Medals.—To Messrs. Allwood Bros., for Carnations and Pinks; Messrs. Bakers, Ltd., for shrubs and Conifers; Mr. E. Ballard, for Michaelmas Daisies; Messrs. R. H. Bath, Ltd., for Gladioli; Messrs. W. Blom and Son, for Colchicums; Messrs. G. Bunyard and Co., Ltd., for Conifers and other trees and shrubs; Messrs. A. Charlton and Sons, for trees and shrubs; Mr. J. W. Forsyth, for early-flowering Chrysanthemums; Mr. S. J. Goodliffe, for herbaceous plants and shrubs; Messrs. Harrods, Ltd., for Box and Bay trees; Mr. H. Hemsley, for trees and shrubs; Messrs. Hillier and Sons, for Conifers; the Hollambys Nurseries, for ornamental vines and shrubs; Messrs. Isaac House and Son, for Scabious and Kniphofias; Messrs. Stuart Low and Co., for Carnations; Messrs. Stuart Low and Co., for Orchids; Messrs. Keith Luxford and Co., for early-flowering Chrysanthemums; Mr. J. H. Pemberton, for Roses; Messrs. E. J. Redgrove and Son, for herbaceous plants; Messrs. J. Robinson and Son, for rock garden and herbaceous plants; and to Messrs. Wm. Wood and Son, Ltd., for Michaelmas Daisies.

Flora Medals.—To Mr. W. J. Marchant, for trees and shrubs; and to Messrs. J. Scott and Co., for shrubs and Conifers.

Banksian Medals.—To Messrs. G. and A. Clark, Ltd., for herbaceous plants; Messrs. G. and A. Clark, Ltd., for trees and shrubs; Messrs. Wm. Cutbush and Son, Ltd., for shrubs; Messrs. E. F. Fairbairn and Sons, for Phloxes; Mr. J. Golding, for Scabious; Mr. H. Hemsley, for rock garden plants; Mr. Gavin Jones, for herbaceous plants and shrubs; Mr. John Klinkert, for clipped Box trees; Messrs. H. Langridge and Co., for Dahlias; Messrs. Stuart Low and Co., for Conifers and shrubs; Messrs. Patricks, for Conifers and shrubs; Mr. Amos Perry, for hardy plants; Mr. F. Rich, for Michaelmas Daisies; Messrs. Rich and Cooling, for herbaceous plants; Mr. Charles Turner, for Dahlias; and to Mr. W. Yandell, for early-flowering Chrysanthemums.

⁂ The report of this show will be continued in our next issue. — Eds.

The following awards have been made to the undermentioned flowers and vegetables by the Council of the Royal Horticultural Society after trial at Wisley.

Herbaceous Veronicas.

AWARDS OF MERIT.

(8) *rupestris*, sent by Messrs. John Forbes, Ltd., and (14) *prostrata* (synonymous with rupestris) by Messrs. J. Kelway and Sons; (9) *prostrata var. alba*, by Messrs. G. Arends; (19) Shirley Blue, by Messrs. Den Ouden; (21-24), *Royal Blue*, by Messrs. Den Ouden, Messrs. John Forbes, Ltd., Messrs. J. Kelway and Sons, and Messrs. Barr and Sons; (26) *austriaca*, by Messrs. John Forbes, Ltd.; (37, 38), *gentianoides*, by Messrs. John Forbes, Ltd., and Messrs. Den Ouden; and (57) *longifolia*, sent by Messrs. Barr and Sons.

HIGHLY COMMENDED.

(11) prostrata var. pallida, sent by Messrs. G. Arends; (25) True Blue, by Messrs. Barr and Sons; (30) incana, by Messrs. Barr and Sons; and (51), Blue Peter, sent by Mr. W. A. Collier.

Delphiniums.

AWARDS OF MERIT.

Ann Baker, sent by Messrs. Baker, Ltd.; *Mrs. Newton Lees*, by Messrs. Blackmore and Langdon; *Dawn*, by Mr. Spencer; *Cambria*, by Mr. Spencer; and *Sir Douglas Haig*, sent by Messrs. Blackmore and Langdon.

Perennial Gaillardias.

HIGHLY COMMENDED.

(1) Gloria, (2) Rownham's Queen, and (5) maximum var. triumphans, all sent by Messrs. B. Ladhams, Ltd.

Annual Poppies.

AWARDS OF MERIT.

(1) *Taplow Pink* (somniferum), and (2) *New Double Queen*, both sent by Messrs. Barr and Sons.

Bearded Irises.

FIRST CLASS CERTIFICATE.

Class IVb.—(372). *Souvenir de Madame Gaudichau*, sent by Messrs. R. Wallace and Co., Ltd., and Mr. G. P. Baker.

AWARDS OF MERIT.

Class II Aa(1).—(990) *Blue Chintz*, sent by Mr. F. Burton.

Class IVa.—(940) *Sir Michael*, sent by The Orpington Nurseries Co. Ltd.; (178) *Yeoman*, by The Orpington Nurseries Co., Ltd.; and (965) *Rhein Traube*, sent by Messrs. John Waterer, Sons and Crisp, Ltd.

Class IVb.—(189) *Abdera*, sent by Mr. Amos Perry; (345) *Centurion* and (640) *Lent A. Williamson*, by The Orpington Nurseries Co., Ltd.; and (997) *India*, sent by Mr. G. L. Pilkington.

Class IVc.—(327) *Romola*, sent by The Orpington Nurseries Co., Ltd.

Class Va.—(396) *Mlle. Yvonne Pelletier*, sent by Messrs. Cayeux; (414), *Norma*, by Mr. Amos Perry; (419), *Bluet*, by The Orpington Nurseries Co., Ltd.; (431) *Benbow*, by Mr. A. J. Bliss; (448) *pallida var. dalmatica*, by the R.H.S., Messrs. John Forbes, Ltd., and Messrs. R. Veitch and Son; and (904), *pallida*, *Shotsham variety*, sent by The Orpington Nurseries Co., Ltd.

Class Vb.—(439) *Harmony*, sent by The Orpington Nurseries Co., Ltd.; and (466) *Parc de Neuilly*, sent by Messrs. Barr and Sons.

Class Vc.—(484), *Aphrodite*, sent by The Orpington Nurseries Co., Ltd.; and (485) *Mrs. Marion Cran*, sent by Mr. Amos Perry.

Class VIa (1).—(574) *Nemoralia*, and (590) *Hemodus*, sent by Mr. Amos Perry.

Class VIc (1).—(656) *Lord Lambourne*, sent by Mr. Amos Perry; and (691) *Bruno*, sent by Messrs. R. Wallace and Co., Ltd.

Class VIc (2).—(672) *Mr. H. F. Bowles*, sent by Mr. Amos Perry; and (684) *Iris King*, sent by Messrs. Barr and Sons, and by Mr. Amos Perry.

Class 7c.—(831) *Rialgar*, sent by Miss Sturtevant.

Class 7d.—(747) *Flaming Sword*, sent by The Orpington Nurseries Co., Ltd.

Class 8a.—(1014) *Gold Imperial*, sent by Miss Sturtevant.

Class 8b.—(834) *Flutter-by*, sent by Miss Sturtevant.

Cabbage Lettuces.

AWARDS OF MERIT.

(60) *Unrivalled*, sent by Messrs. Middlehursts, and (61) *Market Favourite or Unrivalled*, by Messrs. Clucas (alike); (69) *Konfit*, by Messrs. Daehnfeldt and Jensen, and (76) *Yellow Longstanding*, by Messrs. Heinemann (alike); and (106, 107, 108, 109) *Continuity*, sent by Messrs. Daniels Bros., Messrs. W. H. Simpson, Messrs. Barr and Sons, and Messrs. Dobbie and Co.

HIGHLY COMMENDED.

(15) New York, sent by Messrs. Cooper; (16) New York selected, by Messrs. Finney; (18) Neapolitan, by Messrs. Dobbie and Co.; (19) Wonderful or New York, by Messrs. Clucas; (20 to 25) Wonderful, by Messrs. Dobbie and Co., Ltd., Messrs. Morris, Messrs. Webb and Sons, Ltd., Messrs. Middlehursts, Messrs. Daehnfeldt and Jensen, and Messrs. Harrison; and (26) Hercules, sent by Messrs. Dobbie and Co. (all alike); (44 to 50) May King, sent by Messrs. Dickson and Robinson, Messrs. Harrison, Messrs. Heinemann, Messrs. Clucas, Messrs. Middlehursts, Messrs. Olsen and Messrs. Zwaan and van der Molen; (52) *Paragon*, sent by Messrs. E. Webb and Sons, Ltd.; (53) Trocadero, by Messrs. Nutting, and (104) Big Boston, by Messrs. Burpee (alike); (54) White Big Boston, sent by Messrs. Burpee, and (74) Bohemia, by Messrs. Heinemann (alike); (67) Best of All, by Messrs. Heinemann; (79 to 82) Perfect Gem, sent by Messrs. R. Veitch and Son, Mr. Dawkins, Messrs. Nutting and Messrs. James Carter and Co.; (85, 87, 88), Wayahead, sent by Mrs. Burpee, Messrs. Barr and Sons, and Messrs. James Carter and Co.; (94) Defiance Long Stander, sent by Messrs. Clucas; (110) Californian Cream Butter, by Messrs. Burpee; (140, 141, 143, 144, 145), Tom Thumb, sent by Messrs. Morris, Messrs. W. Simpson, Messrs. Speed, Messrs. Olsen, and Messrs. Dobbie and Co., and (147, 148), Tom Thumb Selected, sent by Messrs. E. Webb and Sons, Ltd., and Messrs. Barr and Sons (all alike).

COMMENDED.

(91) Distinction, sent by Messrs. Dickson and Robinson; (123) All the Year Improved Round, sent by Messrs. Cooper; (124 to 133) All the Uear Round, sent by Messrs. Cooper, Messrs. Finney, Messrs. W. Simpson, Messrs. Clucas, Messrs. Middlehursts, Messrs. Cullen, Messrs. R. Veitch and Son, Messrs. Nutting, Messrs. Barr and Sons and Messrs. Dobbie and Co.; (135) All the Year Round re-selected, sent by Messrs. James Carter and Co.; (136) Criterion, by Messrs. E. Webb and Sons, Ltd. (all alike); (149) Winter Density, sent by Messrs. Nutting.

Tomatos.

AWARDS OF MERIT.

Radio, sent by Messrs. W. H. Simpson, and *Essex Wonder*, sent by Messrs. Dobbie and Co., Ltd.

READING GARDENERS'.

The first fortnightly meeting of the autumn session was held in the Abbey Hall, on Monday, September 23, when the President, Mr. Frank E. Moring, presided over a very large attendance of members.

Unfortunately, the lecturer, Mr. S. E. Smallridge, was prevented from attending by illness, but Mr. E. J. Dore, at a short notice, kindly filled the breach, and gave a very useful and practical talk on the herbaceous Calceolaria. He described very fully the treatment of these beautiful greenhouse plants from seed-sowing to the flowering period. Soils and manures, as well as diseases and pests were ably dealt with. An excellent discussion followed, sustained by Messrs. Blackwell, Gower, Cook, Reeves, Reed, Waite, Simmons, Goddard, Young, Clacy and Dearlove.

The exhibits in the two sections were quite a feature.

In the competitions arranged for the evening, the following were the results :—

For three vases of flowers, three distinct kinds, outdoor grown, the first prize was awarded to Mr. A. W. Gower, The Gardens, Calcot Grange; second, to Mr. A. Manley, The Gardens, Highfield, Heckfield; and third, to Mr. T. F. Packer, Collis Road, Reading. For a vase of Roses there was only one entry, but Mr. F. W. Rabbetts, The Gardens, Bulmershe, Earley, richly deserved the first prize awarded for the beautiful blooms staged.

In the non-competitive section, several excellent exhibits were staged, no fewer than five First Class Certificates being awarded—quite a record.

The Dowty's Rosery, Elvenden Lane, Wokingham, had a magnificent stand of Roses, all first-class blooms for so late in the season, such varieties as Shot Silk, Mrs. H. Bowles, Golden Ophelia, Etoile de Holland, Madame Butterfly, Betty Uprichard, Los Angeles, and Roselandia being prominent. (F.C.C. and congratulations of the Association). By the kindness of Mr. Dowty, these flowers were sent to the hospital after the meeting. Mr. T. Waite, Whitley Wood Lane, Reading, exhibited a collection of Michaelmas Daisies, Pompon Dahlias and Carnations (F.C.C.) Mr. A. W. Gower showed three dishes of splendid fruits namely, Sea Eagle Peaches, Coe's Golden Drop Plums and Worcester Pearmain Apples. Mr. E. Blackwell, The Gardens, Foxhill, Reading, received two First Class Certificates, one for very fine bulbs of Ailsa Craig Onions, and the other for some very fine examples of outdoor-grown Peaches, Sea Eagle and Princess of Wales.

ROYAL SCOTTISH ARBORICULTURAL.

Aberdeen Branch.

One of the most delightful and successful excursions ever enjoyed by the members of this branch took place on Saturday, September 28. The venue was the beautiful woodlands of Ballogie on Royal Deeside, Aberdeenshire, owned by Colonel R. J. Nicol. Set like a gem in one of the most beautiful districts of Scotland, Ballogie was looking its very best, the glorious sunshine and the autumnal tints on the trees forming a picture that must long remain in the memories of the visitors.

Led by Colonel Nicol and his forester, Mr. J. R. Bell, the company, numbering over fifty, was a most representative one, and included Lord Forbes, President of the Branch; Sir Sydney J. Gammell, of Countesswells; Colonel Lilburn, of Coull; Colonel A. H. Farquharson, of Invercauld; Mr. John Michie, M.V.O., erstwhile commissioner and head forester, Balmoral Castle; Messrs. James Walker, Duncairn; J. A. Anderson, Fettercairn; Johnston Edwards, Balmoral Castle; E. C. Duthie, Aberdeen; and Mr. Robert Adam, Secretary of the Branch, etc.

To the practical and expert woodman, the Ballogie woodlands make an exceptional appeal, for here are found lessons and statistics not often enough found on wooded estates. Meticulous records are kept which enable the visitor to see at a glance the history, plantings, costs, and species of trees of every wood on the estate. There are over 4,000 acres of woodlands on the estate, mostly under Scots Pine and Larch.

Starting on their tour, the members were first shown a specimen of a London Plane, supposed to be the only one in Aberdeenshire or Kincardineshire. It looked remarkably healthy and appeared well pleased with its strange neighbours and habitat. The Green Bank Wood, facing the river Dee as it meanders through the estate, was next visited; it comprises a fine, healthy young plantation, the higher parts planted with Scots Pine and the lower with Larch. The advantages derived from a fairly heavy thinning were seen at Carlogie Wood, some two hundred acres in extent. Here Colonel Nicol explained that his late father received 1s. 0½d. per foot for Scots Pine cut from this wood before the war—considered a record at that period. At Craigmore Wood was seen an object lesson on the planting activities now practised on the estate. Started in 1922-1923, 207 acres of Scots Pine, without any mixture, have been planted at a cost of £3 13s. 7d. per acre. The young trees look remarkably well. Getting on to the drive to Ballogie House, the party found several monarchs of the woodlands worthy of their admiration, including a Sitka Spruce with a girth at five feet up of fourteen feet, an increase of two feet three inches since 1912, when it was last measured. One fine Scots Pine, girthing twelve feet eight-and-a-half inches, with a clean bole of forty feet six inches, and standing 110 feet high, evoked much admiration. At this point a controversy arose as to the identity of two superb Firs. Colonel Nicol explained that when the parent society last visited Ballogie a keen difference of views arose as to what the Firs were. Then three different views were expressed, and later an outside expert was consulted by the Colonel. According to this expert, the views of all the others were entirely wrong, and he gave the opinion that the trees were, respectively, an Abies grandis and an A. amabilis. Mr. Michie, who was also present at the origin of the controversy, reiterated the opinion he expressed in 1912, that one of the trees was A. Nordmanniana.

After lunch, a business meeting of the Branch was held, when Lord Forbes expressed the great gratification the party felt at being allowed to visit such a wonderful forestry estate. There are few estates in this county or, perhaps, in Scotland, he said, where there are better preserved records, or which are so fortunate in having a proprietor who takes such an endless amount of trouble to maintain them as Colonel Nicol does at Ballogie. Lord Forbes also paid a warm tribute to Mr. J. R. Bell, the forester, for the fine part he is playing in the Ballogie woodlands. Colonel Nicol made suitable reply.

The afternoon was devoted to a ramble over the estate, visits being paid to a fifteen-acre plot set apart entirely for the cultivation of Corsican Pine, the nurseries, some fine examples of naturally regenerated Larch, etc. And thus came to an end what could truly be described as "a perfect day." These feelings Mr. John Michie aptly voiced in the vote of thanks he proposed to Colonel Nicol, and which was enthusiastically passed by the company.

Obituary.

Mrs. Edwin Beckett.—The news of the sudden and totally unexpected death of Mrs. Edwin Beckett has come as a great shock to us and to all friends who have received the sad news. Mr. and Mrs. Beckett enjoyed a short holiday at Brighton, and were just ready to begin the return journey to Aldenham, when Mrs. Beckett succumbed to a sudden attack of heart trouble. After a period of over fifty years of married life, this sudden bereavement is an almost overwhelming one for the veteran gardener and exhibitor—Mr. Edwin Beckett, V.M.H.—whose connection with the famous gardens at Aldenham House, Elstree, is a matter of general knowledge among horticulturists, all of whom will join with us in deepest sympathy with him in his sad and irreparable loss.

ANSWERS TO CORRESPONDENTS.

Fruit Tree Roots Diseased.—*J. R.* The fruit tree roots are covered with the hyphae of a saprophytic fungus, so that one cannot diagnose the real cause of the trouble. As your losses in fruit trees are so general and widespread, the cause is probably due to the soil, which appears to be sour and badly drained. The material and information submitted are so scanty that a satisfactory reply to your queries is impossible. Send further material of roots and branches taken from a slightly affected tree.

Gladioli Diseased.—*E. P. D.* The Gladioli are suffering from Fusarium wilt disease. See reply to *H. P.* in *Gard. Chron.* of September 6.

Grapes Discoloured.—*W. R.* The Grapes are infected with the fungus, Botrytis cinerea. The primary cause is the production of a static atmosphere due to faulty ventilation. The remedy is to improve upon your present method of ventilation. A constantly moving atmosphere will prevent the formation of drops of water on the berries. Remove and burn all cracked berries.

Names of Plants.—*W. W. W.* Your specimens had been packed too damp, and in consequence had heated, many of them being in a decayed condition, rendering identification impossible; many of your numbers were also detached or undecipherable through the damp. 1, Armeria plantaginea; 2, Saxifraga Aizoon var.; 3, Acaena inermis (?); 4, Thymus Serpyllum var. lanuginosus; 6, Hieracium species; 7, Lysimachia Nummularia; 8, Veronica loganioides; 9, Scabiosa Pterocephala; 13, Geranium species; 15, Artemisia species; 16, Senecio Ledebourii; 17, Eupatorium purpureum; 18, Lycopus europaeus; 19, Astilbe variety.—*D. M.* 1, Sempervivium caespitosum × S. canariensis; 2, Cotyledon species; 3 and 6, C. secunda (syn. Echeveria secunda); 4, C. secunda var. major; 5, C. clavifolia; and 7, Rhodostachys pitcairniaefolia.

Oak Twigs with Galls.—*E. D. W.* The gall on the Oak shoots is a common one, usually known as the Hop or Artichoke gall. It is set up by one of the gall wasps or Cynipidae, Andricus pilotus var. fecundator. The general health of the tree is unaffected by the presence of these galls.

Peach Diseased.—*E. P. R.* The Peach fruit is affected with a fungus disease, Cladosporium carpophilum. Pick off and burn all scabbed fruits at once, and spray the fruits soon after forming, and again in June, with Bordeaux mixture.

Plum Leaves infested with Gall Mites.—*G. R. N.* The Plum foliage is heavily infested with gall mites, Eriophyes phloeocoptes. The mites are microscopic in size so that the spiders you see running about on the leaves are in no way connected with the galls. The infested tree should be thoroughly sprayed during the first week in February with lime-sulphur, using one gallon of lime-sulphur to twelve gallons of water.

Tomato Fruits Netted.—*M. M.* The netted marking on the Tomato fruits is due to sunburn during prolonged periods of intense sunshine. Where this phenomenon occurs, the house should be shaded with limewash and varieties with dense foliage grown in preference.

Vine Leaves Scorched.—*F. G. G.* The vine foliage is free from the attack of any pathogenic organism. The cause of the burning or scalding may be attributed to defective glass, *i.e.*, glass of uneven thickness or containing bubbles, concentrating the sun's rays on certain spots. Faulty watering and ventilation will produce similar effects on vine leaves.

MARKETS.

COVENT GARDEN, Tuesday, October 1, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—The general supplies throughout this department are still very heavy and somewhat varied in quality, especially Carnations, the majority being very ordinary, although prices are on the up grade. There is a glut of coloured spray Chrysanthemums, but spray white is more limited and consists of Roi des Blancs and September White. Disbudded blooms, medium size, both white and coloured are more than sufficient for present requirements, larger white blooms being more limited; the principal sorts on offer are Almirante, Alcalde, Debutante, Delight, Pink Profusion, September Glory, Bronze Consul, Yellow King, Yellow Cranford, Pink Cranford and Sanctity. The following Roses are arriving in excellent condition:—Hoosier Beauty, Madame Butterfly, Golden Ophelia, Pink Ophelia, Roselandia, Sylvia and Richmond. L. longiflorum is the most plentiful among Liliums, L. speciosum var. rubrum and L. auratum being somewhat limited, as also is Lily-of-the-Valley. The newest arrivals in this department are single Violets Princess of Wales, but they are not recommended, the present weather conditions being against the successful carriage of the blooms. A few white Camellias are now on offer.

Remarks.—So far as the English fruit section of the market is concerned, supplies are on the heavy side, and Apples in particular are plentiful. Good fruits of dessert and cooking Apples, however, have sold well, but the quantities of medium and second grade Apples have been assuming record proportions, with resulting poor prices. Some Apples have been available from Canada and the United States, but have not sold well. Hothouse Grapes are quoted at lower rates, the competition of Belgium and Dutch Grapes affecting values obtainable for English Grapes. Some good Peaches are still available, which remain at a comparatively high price level. Plums have been plentiful, but meeting an excellent enquiry; they have not been cheap, and those available from now onwards will continue to sell well. Pears are a slightly improved trade, especially for good specimens. Some Blackberries, both cultivated and hedge fruits, are meeting a good demand. Tomatos have been a better trade, especially the best marks, which are realising improved prices. Cucumbers are a firmer market and better prices are being returned to growers. Mushrooms are available in larger quantities, but values are remaining fairly steady. There is a better tone in the vegetable market, and Peas, Brussels Sprouts and Cabbages are selling well. Salads also remain in good demand, and there is an improved tone in the Potato market, due probably to cooler weather conditions.

GLASGOW.

The tone of the cut flower market was rather steadier during the past week, and in a few instances prices were distinctly firmer. Carnations, which have been plentiful and exceptionally cheap throughout the summer, were in better demand at values ranging from 1s. 9d. to 3s. 6d. per dozen, while Roses were worth from 3s. to 3s. 6d. and Richardias from 4s. to 4s. 6d. per bunch. Chrysanthemums also yielded a better return to the producer; special blooms sold at 3s. to 6s. per dozen; disbudded. yellow, 9d. to 1s. 6d. for 6's; pink and bronze, 9d. to 1s. 3d.; white, 8d. to 1s. 3d.; and sprays (all colours), 2d. to 8d. per bunch. Other quotations were as follow:—Michaelmas Daisies, 3d. to 6d. per bunch; Dahlias, 2d. to 4d.; Asparagus, short, 3d. to 6d.; medium, 9d. to 1s. 6d.; long, 1s. 6d. to 2s. 6d.; A. Sprengeri, short, 2½d. to 4d.; medium, 4d. to 6d.; long, 8d. to 1s. 3d.; Smilax, short, 9d.; medium, 1s. 3d.; long, 1s. 6d. to 2s.

In the fruit market, Victoria Plums continued to command 6d. to 9d. per lb. for first-grade fruits, and 2½d. for second; while Damsons sold at 3d. to 4d.; Blackberries, 5d. to 6d.; cooking Apples, 2d. to 3d.; hothouse Grapes, 2s. to 3s. 6d. per lb.; and Pineapples, 5s. each. Tomatos improved to 6d. to 7½d. per lb., but Jersey produce was cheap at 2d. to 2½d.

Vegetable prices showed little movement either way. Cauliflowers realised 1s. 6d. to 3s. per dozen; Lettuces, 1s. 6d. to 2s. 6d. per box of 15 or 18; Cucumbers, 3s. to 5s.; Guernsey Beans, 8d. per lb.; Runner Beans, 2d. to 3d., and Mushrooms, 2s. 6d.

SCHEDULES RECEIVED.

Highgate and District Chrysanthemum Society.—Forty-second Annual Exhibition at the Highgate Hall, Highgate, on Wednesday and Thursday, November 13 and 14, 1929.—Secretary, Mr. W. Kiy, 16, Holmesdale Road, Highgate, N.6.

Lincolnshire County Agricultural Education and Horticultural Committees.—Potato Show to be held in South Lincs. Engineering Company's Garage, Westlode Street, Spalding, on Thursday, October 24, 1929.—Secretary, Mr. J. C. Wallace, Agricultural Institute, Kirton, near Boston, Lincs.

Taunton and District Chrysanthemum and Fruit Society.—Fifteenth Annual Show of Chrysanthemums, Flowers, Fruits and Vegetables, in the Territorial Hall, Taunton, on Wednesday and Thursday, November 6 and 7, 1929.—Secretary, Mr. W. H. Loosemore, Sundown, Kingston Road, Taunton.

Hull and East Riding Chrysanthemum Society.—Twenty-ninth Chrysanthemum Show, in the City Hall, Hull, on Wednesday and Thursday, November 20 and 21, 1929.—Joint Secretaries, Mr. E. Mennell, 10a, Spring Street, Hull, and Mr. W. O. Hartenfeld, 24, Cranbourne Street, Hull.

Sheffield Chrysanthemum Society.—Forty-second Annual Show, in the Artillery Drill Hall, Edmund Road, Sheffield, on Thursday, Friday and Saturday, November 14, 15 and 16, 1929.—Secretary, Mr. F. B. Hyde, 42, City Road, Sheffield.

Guildford and District Chrysanthemum Society.—Thirty-seventh Annual Exhibition, in the Borough Hall, Guildford, on Wednesday and Thursday, October 30 and 31, 1929.—Secretary, Mr. Walter Miles, Ashbrook, Cadogan Road, Surbiton.

Hitchin Chrysanthemum Society.—Annual Exhibition in New Town Hall, Hitchin, on Thursday, November 14 1929.—Secretary, Mr. W. G. P. Clark, 4, York Road, Hitchin.

CATALOGUES RECEIVED.

Andrew Ireland and Hitchcock, Marks Tey, Essex.—Sweet Peas, Bulbs and Roses.
H. G. Longford, Abingdon, Berks.—Bulbs, Alpine Plants, Polyanthuses, Carnations, Herbaceous Plants.
Clibrans, Altrincham.—Fruit Trees and Bushes, Fruit Trees in Pots, etc.
Clibrans, Ltd., Altrincham.—Roses.
Morse Bros., Melton, Suffolk.—Roses.
R. F. M. Wiltshire, Netley Abbey, Southampton.—Sweet Peas.
Alex. Dickson and Sons, Ltd., Hawlmark, Newtownards, Co. Down.—Roses.
William Power and Co., Waterford.—Bulbs.
Sale and Son, Ltd., Wokingham.—Roses, Fruit Trees, Hardy Shrubs and Trees, Vegetables, Flowering Plants and Bulbs.
Benjamin R. Cant and Sons, Ltd., Colchester.—Roses.
Finney's, Newcastle-on-Tyne.—Bulbs, Roses, Fruit Trees, etc.
John Waterer, Sons and Crisp, Ltd., Twyford.—Rhododendrons, Azaleas, Conifers, Shrubs, Climbers, etc.
William Watson and Sons, Ltd., 31, Nassau Street, Dublin.—Roses.

FOREIGN.

Albert and Emile Jahandiez, Carqueiranne (Var) France.—Cacti, etc.

GARDENING APPOINTMENT.

Mr. Ralph E. Arnold, formerly gardener at Kiftsgate Court, has been appointed gardener to Captain Claude Robinson, M.C., Moor Wood, Cirencester, Gloucester. [Thanks for 2s. for R.G.O.F. Box.—Eds.]

The Fig Tree.

Ever since the first lady made the first abbreviated skirt from its leaves, the Fig tree has filled a considerable place in the history and affections of the human race. Its economic importance is considerable, especially in warmer countries than our own, but even with us the fruits grown under glass realise good prices in the market, while as an item in a choice selection of dessert fruits, a " first ripe Fig " is a *bonne bouche* for many people. During the present year Fig trees have enjoyed the sunshine, warmth and dry atmosphere experienced, so that even bush trees in the open—the old Brown Turkey variety—have not only yielded fruits in plenty but have ripened large numbers, as in the case of a group of small trees we have noticed in the Boston Manor Park, a former residence of the Clitheroe family, and now the prized possession of the citizens of Brentford. A few folk dislike Figs, but those who have enjoyed fully ripe fruits, plucked and eaten at just the right moment, desire a frequent repetition of that experience. The late Mr. A. F. Barron, when Superintendent of the Royal Horticultural Society's Gardens at Chiswick, knew what was good among fruits; although his sense of smell was almost negligible, his sense of sight was good, while his sense of taste was in excellent order, as shown by his careful selection of the right fruits of the right variety at the right time from among the Figs, of which the Society then had an unique collection grown in pots. His particular favourite was Bourjassote Grise and the fruit must have a " tear in its eye " to be perfect. Our own appreciation of Figs dates from an association with Mr. Barron. But although the Fig tree may not bear its wonted fruits, it is, nevertheless, a useful tree or shrub for the garden, its broad, rich green leaves making it a handsome foliage subject, while its grey-green stems add a note of distinction. Moreover, despite its eastern origin, the Fig tree is wonderfully hardy, and for garden decoration it asks no favours. There is a tall specimen of fine appearance on the railway embankment at the beginning of a deep cutting (going westward) that leads to Earls Court Station on " the Underground " ; it could hardly be in a worse position, yet it flourishes, although whether it fruits or not is known only to the railwaymen. Then, also, further evidence of the hardiness and beauty of the Fig tree as a town plant is to be found along the front of the National Gallery, overlooking Trafalgar Square, where many trees are trained close to the wall and provide a fine screen of foliage year after year. We believe that as a town tree and as a decorative garden plant the Fig has not received the honour due to it. Mr. W. J. Bean, in his *Trees and Shrubs Hardy in the British Isles*, is not kind to the Fig. He tells us that " in the open at Kew the fig gets to be a shrub 6 to 10 feet high, according to the mildness or otherwise of successive winters. The severest frosts cut it to the ground, whence strong young shoots spring up the following summer. Only once or twice in twenty years has it borne palatable fruit." And yet, across the River Thames, a couple of miles north of Kew, quite unsheltered, Fig trees have withstood the rigours of the past winter and the drought of the summer uninjured, and all will agree that 1929 has provided a severe test of hardiness.

Linnean Society's Annual Dinner, 1929.—The Linnean Society will hold its Annual Dinner at the Criterion Restaurant, Piccadilly Circus, London, on Thursday, October 31, at 7.15 p.m. Fellows and Associates may invite friends, and must obtain tickets for the dinner, price 8s. 6d. each (exclusive of wine and attendance, but including coffee), from the Assistant Secretary, not later than Monday, October 28. A Reception by the President, Sir Sidney F. Harmer, K.B.E., F.R.S., will be held in the Rooms of the Society, Burlington House, at 9 p.m. on the same evening.

Orchid Competitions for Amateurs.—At the Royal Horticultural Society's special show for Orchids and other stove and greenhouse plants which will be held on Wednesday and Thursday, October 23 and 24, 1929, the following cups and trophies are offered for award to amateurs :—The Schröder Challenge Cup, presented to the Society by Baron B. Schröder, and offered for award to the best exhibit of Orchids shown by an amateur (groups entered for this cup must be distinct from those entered in competition for the Orchid Challenge Cup presented by the Orchid trade for groups of limited area); a Challenge Cup presented by the Orchid trade for the best group of Orchids staged in a space not exceeding sixty square feet, by an amateur who employs not more than three assistants in his Orchid houses, including the head gardener; a Silver Trophy, presented by the Orchid trade for the best twelve Orchids, not more than two of one genus, exhibited by an amateur who employs not more than two growers, including the head gardener, in his Orchid houses; and a Silver Trophy presented by the Orchid trade for the best six Orchids exhibited by an amateur who employs not more than one Orchid-grower or gardener. Entries for these competitions must reach the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1, not later than by the first post on Wednesday, October 16. At 3 p.m. on the first day of this show, October 23, a lecture on " Orchid-growing for Beginners" will be given by Mr. H. G. Alexander, V.M.H., who for many years had charge of the late Sir George Holford's famous collection. As it is impossible for Sir Jeremiah Colman, Bt. (Chairman of the Orchid Committee), to be present on this occasion, the Chair will be taken by Mr. Charles H. Curtis, F.L.S.

Fowey Woods, Cornwall.—The beautiful Fowey Woods, which form so delightful a setting to The Headland, at Fowey, have been purchased by the Fowey Town Council, and will be dedicated to the use of the public by the Lord Lieutenant of the Duchy on October 17. As the Headland is already public property, the addition of Fowey Woods will complete and preserve to the public one of the most delightful scenes along the Cornish coast.

Horticultural Conference at Sutton Bonington.—At a recent horticultural conference, held at the Midland Agricultural College, Sutton Bonington, Loughborough, Mr. L. N. Staniland, A.R.C.Sc., of the Long Ashton Fruit Research Station, gave an address on "The Pests and Diseases of the Strawberry Crop." After describing the normal life of the plant, the speaker lucidly described the diagnostic features of the diseases known as Red Plant, Cauliflower, and Blindness or Multiple-crown, and the symptoms of aphis and red spider attacks. The production of small leaves is the chief sign of an unprofitable plant, and in the great majority of cases this has been brought about by aphis attack. It was stated that once severely attacked, the plant never recovers. The speaker then pointed out the practical means of overcoming serious damage. The beds should be rogued at the flowering time and again about October ; all runners should be dipped in nicotine solution before planting, and beds should be sprayed with nicotine or given a dry dusting after the fruits are gathered. A prolonged discussion followed, after which a hearty vote of thanks was accorded Mr. Staniland.

A Proposed Rock Garden Society.—A meeting will be held in the Fruit Committee Room, on the second floor—reached by both lifts—of the new hall of the Royal Horticultural Society, on Wednesday, October 23, at 4 p.m., to discuss the desirability of forming a Rock Garden Society; everyone interested in the subject is invited to attend.

The "Select List of Roses."—Rose growers in general will welcome the publication by the National Rose Society of a new edition of the invaluable *Select List of Roses and Instructions for Pruning*, issued now, instead of in March next, in the hope that it may prove of value to growers intent upon making fresh plantations this autumn. The book has been brought up-to-date, and all new Roses included in the list have been grown by some member of the Publications Committee.

New Jersey Orchids.—The Pine Barrens of New Jersey would appear to be a veritable happy hunting ground for lovers of the fascinating terrestrial Orchids, if one may judge from the extremely interesting, and well-illustrated account, by Mr. J. Fletcher Street, of "The Orchids of the New Jersey Pine Barrens" in the *Year Book* of the Academy of Natural Sciences of Philadelphia, for the year ending December 31, 1928. Mr. Street states that the two elements which seem, with few exceptions, to be necessary for the proper development of these plants, namely, abundant moisture and a high degree of soil acidity, exist almost uniformly throughout that area of New Jersey known as the Pine Barrens. Here are almost uninterrupted Pine forests and large swamp areas bordered with Cedar and deep with Sphagnum-moss—an uncultivated and neglected expanse wherein flourish some twenty or more distinct Orchids. The first to bloom, in May, is Cypripedium acaule, " to be looked for in any Pine woods where the needles lie thick and deep," while in early June, in swamps in the upper part of the State, and in association with Royal Ferns, the rare Showy Lady's Slipper, Cypripedium reginae, is to be found after much searching. The rosy-purple-flowered Arethusa bulbosa, stated to be not uncommon in some of the bogs bordering the coastal marshes, produces its butterfly-like blooms also about the beginning of June, to be followed in about fifteen days by the more common Grass Pink, Limodorum tuberosum (Calopogon pulchellus), which is stated by Mr. Street to prefer moist, sandy situations and the drier edge of Cranberry bogs. The Rose Pogonia, Pogonia ophioglossoides also flowers at this season, and is to be found in swampy Sphagnum-moss beds, while two others of this race are also stated to occur in the Pine Barrens, *i.e.*, Pogonia divaricata and Isotria verticillata, the former limited to the southern areas and the latter only occurring locally, although it is more common further north. The Southern Twayblade, Listera australis, and Loesel's Twayblade, Leptorchis Loeselii, also occur locally. August would appear to be the most important month for the Orchid lover. The most beautiful of the indigenous flowers, namely, Blephariglottis (Habenaria ?) blephariglottis, the White-fringed Orchis, opens its blooms at this season. It is apparently quite common, and asks no more than "wet feet and an open sky." Less common than this are the yellow-flowered species, B. cristata and B. ciliaris, but where these all grow in association there is a tendency for them to hybridise, with the result that B. Canbyi and B. bicolor are likely to be found. The green-flowered species, B. lacera, with its finely-fringed lip, occurs on the borderland of the seashore, where the Pine Barrens and salt marsh merge. Gymnadeniopsis integra occurs occasionally, while G. clavellata, the Green Wood Orchis, is generally distributed, but is seldom found in large colonies; its flowers are cream coloured. The Snowy Orchis, G. nivea, is found in only one locality in the State, and does not flower until the first week in September, when it produces racemes two inches in length of greyish-white blooms. The shy-flowering Rattlesnake Plantain, Peramium pubescens, delights in rich mould in the Pine forests. Four Ladies' Tresses, species of Gyrostachys, are found within the Pine Barrens. G. vernalis and G. Beckii, small-flowered species, prefer rather dry, sandy soil; G. praecox is found in wet bogs, while G. cernua, the latest to bloom and the most beautiful, is discovered by the Orchid-hunter when roaming through "Gentian meadows."

Protection and Prohibition.—An effort to limit the powers of the U.S.A. Secretary of Agriculture to the legitimate sphere of preventing the admission of injurious pests into the United States, has met with failure. As this effort was made by a considerable body of nurserymen, it is evident that Dr Marlatt's prohibitive measures do not find favour with all his countrymen. Prohibition of the kind adopted by the Federal Board is a two-edged weapon, as the American growers would quickly discover if European countries cared to adopt similar measures in regard to the importation of pests on American fruits. We have reason to believe that foundations for such measures are being prepared—on purely protectionist grounds, of course.

Rothamsted Lectures.—The authorities at Rothamsted are again prepared to give a series of winter lectures. These lectures are especially arranged for the benefit and information of Chambers of Agriculture and Horticulture, Farmers' Clubs and similar organisations who may desire to avail themselves of the facilities thus offered. Certain conditions are laid down, but these and all other information regarding the subjects of the lectures may be obtained on application to the Secretary, Rothamsted Experimental Station, Harpenden, Hertfordshire. Mr. H. V. Garner will be the lecturer on Manures and Manuring (eight lectures); Mr. H. G. Thornton will deal with Soil Bacteria, etc., and Mr. D. W. Cutler with the Biological Aspects of Partial Sterilisation of Soils; Dr. W. E. Brenchley deals with Agricultural Botany; Dr. E. M. Crowther, with Agricultural Chemistry, and Dr. B. A. Keen with Soil Physics. Dr. A. W. Imms and Mr. D. M. Morland lecture on Entomological subjects, while Dr. W. B. Brierley, Dr. J. Henderson Smith and Mr. R. H. Stoughton are the lecturers on Plant Diseases.

Mr. Alexander McBean.—Although still a young man, Mr. Alex. McBean, gardener to the Marchioness of Tweeddale, Yester, Gifford, East Lothian, has been a particularly successful exhibitor of fruits during recent years; he has won over fifty first prizes in the past four years at Glasgow, Edinburgh and Southport. In 1928, he won the Southport Hotels Trophy for a table of dessert fruits at Southport; the *Glasgow Herald* Cup for a table of fruits, at Glasgow; and The Thomson Trophy and Gold Badge for six bunches of Grapes, at Edinburgh; during the present year he repeated all three successes and, in addition, won the R.H.S. Silver Medal and the *Gardening Illustrated* Medal—a splendid record. After leaving school, in 1908, Mr. McBean served his apprenticeship at Cantray Gardens, Inverness-shire, and remained there as journeyman, completing a period of five years. His next post was at Altyre Gardens, where he remained in the glass department until, in 1915, he joined the Royal Field Artillery and served for over three years on active service in France. After demobilisation he went to the famous Keir Gardens at Dunblane, where he became foreman under Mr. T. Lunt—a famous Grape-grower. Then followed a period at Sandringham, where he was promoted to fruit foreman, and remained three-and-a-half years before receiving his appointment at Yester in 1924.

MR. ALEX. McBEAN.

National Rose Society's Exhibitions in 1930. During 1930 the National Rose Society will hold a Summer Show in the grounds of the Royal Hospital, Chelsea; a Provincial Show at Nottingham; a Spring Show at Westminster; a Show of New Roses at Westminster, and an Autumn Show at Westminster. The actual dates are not yet forthcoming.

John Cypher Memorial Fund.—The following amounts have been received (up to October 8), and acknowledged, on behalf of the John Cypher Memorial, by the Hon. Secretary and Treasurer, Mr. Charles H. Curtis, 5, Tavistock Street, Covent Garden, London, W.C.2.—Mr. C. H. Cook, Windsor, £1 1s.; Alderman C. Aveling, Southport, £5; Mr. R. Findlay, Wisley, £1 1s.; Mr. W. B. Cranfield, Enfield Chase, £2 2s.; Mr. T. H. Cook, Sandringham, £1 1s.; Mr. G. Benstead, Richmond, Yorks., £1; Mr. W. Greenfield, Leamington Spa, £1; Mr. R. Kitching, Warter Priory, 5s.; Mr. J. Hathaway, Baldersby Park, Ripon, 5s.; Mr. Edwin Beckett, Aldenham, Elstree, £1 1s.; Mr. H. J. Chapman, Wylam-on-Tyne, £1; Mr. T. Pateman, Brockett Hall, Hatfield, 10s. 6d.; Mr. R. Windsor Rickards, Usk Priory, Usk, £2 2s.; Mr. W. J. Mitchell, Westonbirt, Tetbury, 10s. 6d.; Mr. Robert Hayes, Grasmere, £1 1s.; Mr. T. G. Weston, Chatsworth, £1 1s.; Miss A. B. Moore, Bourton-on-the-Water, £2 2s.; Mr. J. J. Guttridge, Sefton Park, Liverpool, £1 1s.; Mr. S. Barker, Clumber, Worksop, £1 1s.; Mr. A. J. Cobb, The University, Reading, £1 1s.; Dr. F. W. Stansfield, Reading, £2 2s.; Messrs. G. H. Richards, Ltd., Borough High Street, S.E.1, £2 2s.; Mr. Roland D. Smith, Weston Hall, Shifnal, 10s. 6d.; Mr. J. Wood Fitzroy Street, W.1, £2 2s; Mr. Amos Perry, Enfield, £2 2s.; Sir Jeremiah Colman, Bart., Gatton Park, Reigate, £5; Miss E. Perkins, Stratford-on-Avon, 10s.; Mr. A. J. Macself, 148, 149, Aldersgate Street, E.C.1, £1 1s.; the Proprietors, *Amateur Gardening*, 148, 149, Aldersgate Street, E.C.1, £5 5s.; Mr. T. Turton, Sherborne, 10s. 6d.; Captain J. Denton, Long Preston, Yorks., £1 1s.; Mr. A. Mason, Newby Hall, Ripon, 4s.; Mr. W. H. Stansfield, Southport, £1 1s.; Mr. E. Wills, Shirley, Southampton, £1 1s.; Mr. H. Hicks, Manchester, £1 1s.; Messrs. Dickson and Robinson, Manchester, £2 2s.; Mr. Ben Ashton, Wolverhampton, 10s.; Mr. F. Jordan, Ford Manor, Lingfield, £1 1s.; Mr. D. M. Campbell, Regent's Park, £1 1s.; Mr. W. H. Wilson, Worcester, 10s. 6d.; Mr. W. Clark, Hesketh Park, Southport, £1 1s.; and Mr. N. F. Barnes, Eaton Hall, Chester, £2 2s. The Hon. Secretary and Treasurer will be glad to receive the fulfilment of the numerous promises made, and donations from the many personal friends of the late Mr. John Cypher and from others who admired his handiwork at the leading horticultural exhibitions, or received some kindness or advice from him during his long career. Cheques should be crossed "John Cypher Memorial Fund."

The Late Mrs. E. Beckett.—Mr. Edwin Beckett, V.M.H., Aldenham House Gardens, Elstree, writes that he has been overwhelmed with letters of sympathy from the host of friends who saw the announcement of Mrs. Beckett's death in *The Gardeners' Chronicle* of October 5. As it is quite impossible for him to reply to all these letters, he hopes the writers will accept this acknowledgment of their expressions of sympathy.

German Horticultural Appointments.—Some very important changes of positions in the official horticultural world in Germany will be of interest to our readers. The chief manager of the well-known nurseries of L. Späth, in Berlin, Herr Maurer, receives the title of Professor, and is to become Director of the Horticultural Science and Experimental Station, Dahlem, Berlin, a position held for so many years by Professor Th. Echtermeyer. Director Kunert, who for many years had charge of the greenhouse department at Sanssouci, Potsdam, retired with a pension on October 1, and Herr Paul Kache, teacher at Dahlem, will fill the position thus vacated. Herr Erwin Barth, the Director of the Parks and Open Spaces of Berlin, has been appointed Professor of Gardening at the Berlin College of Agriculture. This appointment has given great satisfaction among gardening circles in Berlin, as showing that the Minister of Agriculture is determined that the staff in the horticultural department of the college shall be thoroughly versed in the practical, so well as in the theoretical, side of the work.

Casuals and Caterpillars.—Instead of earning a night's board and lodging by stone-breaking, wood-chopping, Oakum-picking, or similarly usual methods, the Berkhamsted authorities recently set their "casuals" the task of gathering caterpillars from the large areas of green vegetables under cultivation in the district. It is reported that bushels of caterpillars have been gathered and destroyed, but whether the men prefer hunting caterpillars to chopping wood does not appear.

Rain.—Over the greater part of our dried-up country rain has fallen in goodly quantity, and the thirsty earth rejoices. Unfortunately, the needed moisture has not always come like "the gentle rain from heaven," for there have been many storms. Nevertheless, gardeners and nurserymen are looking more hopefully to the planting season, although much more rain is needed to thoroughly moisten the soil about the roots of trees and shrubs. Londoners were highly amused at the beginning of the week, when after heavy rains, and indeed, while rain was falling, the Metropolitan Water Board gave notice of its removal of the ban upon the use of water for gardens.

Friday Street Preservation Fund.—Following upon an appeal made through the columns of *The Times*, the sum of £6,152 has been subscribed towards the £8,500 required for the purchase of the Severells Estate, Surrey, Friday Street as a public open space. The property was to have been offered for sale on Monday, September 30, but the owner, Sir Frederick Richmond, extended the option he had given to the organisers of the Friday Street Fund until October 3. As the required amount was not then forthcoming, he again extended the option for another fortnight, by which time it is hoped that the remainder of the £8,500 required will have been subscribed.

Legacies to Gardeners.—The Right Hon. Sir Charles Ernest Swann, Bart., of Hope Lodge, Westbourne Road, Birkdale, who died on July 13, left £50 to Mr. Henry Rimmer, gardener, if still in his service.—Mr. Philipp Ludwig Robert Martin, of Braidley Road, Bournemouth, who died on July 2, left £300 to his gardener, Mr. L. Gage, and an annuity of £52 to Mrs. Cooper, widow of his late gardener.—Mr. Herbert Melville Beddington, of South Audley Street, Mayfair, London, who died on July 22, left £100 to his late gardener, Mr. Langley.—The Rev. Edward Gepp, of Aston Grays, Knowle Road, Bournemouth, who died on July 31, left an annuity not exceeding £40 to his former gardener, Mr. James Redman, and his wife.

The Drying of Potatos.—The Ministry of Agriculture reports in its *Journal* for October, that, at the instance of the Scottish National Farmers' Union, over 2,750 tons of Potatos have been sliced and dried at the Cupar Beet Factory belonging to the Anglo-Scottish Sugar Beet Corporation. The experiment took place late in the season when the Potatos were not in very good condition, owing to the prolonged storage period, and on that account the experiment was not quite so successful as it would otherwise have been. Over two hundred tons have also been successfully treated at the Eynsham factory belonging to Messrs. Sugar Beet and Crop Driers, Ltd.

Orchid Culture in Ceylon.—The cultivation of Orchids in tropical countries is not necessarily attended with that ease which growers in temperate lands might expect; difficulties have to be surmounted, even in Ceylon, as shown by an illustration of an Orchid house at Kandy, reproduced in the current issue of *The Orchid Review*. The majority of Orchids require protection from tropical sunshine, and in the instance under notice this protection is afforded by constructing a house of rope-netting which is covered by the climbing growths of Asparagus plumosus and similar plants.

Popularising Potato Arran Banner.—With a view to extending the popularity of Potato Arran Banner, Messrs. Dobbie and Co., Ltd., held a special competition for this variety at their headquarters at Edinburgh. Five tubers were required and these had to be of uniform size and shape and approximately ten ounces in weight; 2,000 entries were received from growers all over England, Scotland and Ireland, and the competition proved a great success. The first prize (£15) was awarded to Mr. Walter Underwood, The Cliff, Nearchington, Stafford; second price (£10) to Mr. H. T. Boxer, Oakslea, Hawkinge, nr. Fellton; and third prize (£5) to Mr. T. Moffat, Alston, Cumberland.

Dahlia Show at Haarlem.—This year, from September 19 to 22, the eleventh annual Dahlia Exhibition was held at Haarlem, the great success which attended it being partly due to the suitability of the place in which the exhibits were arranged, namely, the big market hall of the Krelage building. The show was opened formally by the Burgomaster of Haarlem, and several speeches were also made, by Mr. E. Th. Witte, the President of the Netherlands Dahlia Society, and Mr. E. H. Krelage, President of the General Bulb-Growers' Federation. The exhibits were numerous, and comprised a very large number of different varieties.

Royal Horticultural Society's Vegetable Exhibition.—The Vegetable Show held in the Royal Horticultural Society's old Hall, Vincent Square, on October 8 and 9 was a good one, and remembering the difficulties imposed by hot and dry weather, the produce exhibited afforded a fine demonstration of cultural skill overcoming unfavourable climatic conditions. Limitations of space compel us to defer our report of this show until next week.

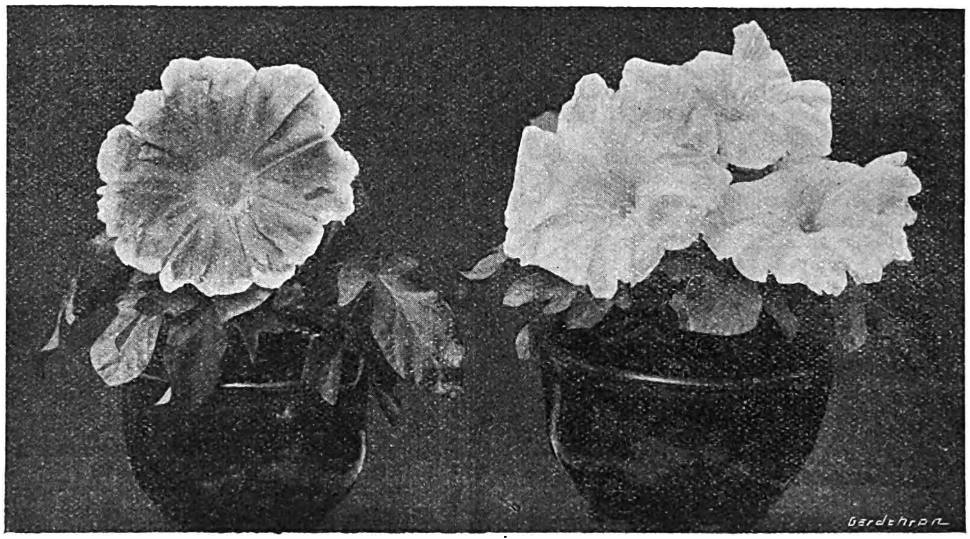

FIG. 134.—JAPANESE MORNING GLORIES.
Left, first prize single-flower plant; right, first prize three-flower plant; at Nagoya Show, July, 1929.
(see p. 282).

Appointments for the Ensuing Week.—MONDAY, OCTOBER 14: Birmingham and Midland Counties Gardeners' Association's lecture. TUESDAY, OCTOBER 15: Winchester Horticultural Society's meeting. THURSDAY, October 17: Ipswich Gardeners' Association's meeting. FRIDAY, OCTOBER 18: Manchester and North of England Orchid Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Sulphur and Water, with a little Lime in it v. Mildew.*—In a small vinery here, thirty-four feet long, two vines were planted, one at each end; three shoots were trained horizontally from each other alternately. At the end of five years the shoots from each had nearly reached the opposite ends; they have been spurred and have borne abundant crops every year, a little fire-heat has been used, and the fruit ripens generally about the middle of August. In June, 1852, although it will be observed the vines were trained horizontally, mildew made its appearance in spots all over the house; a little sulphur was used, but the disease increased over every shoot, leaf and bunch, and the Grapes were nearly all useless. Again in June, 1853, the mildew made its appearance, sulphur was more liberally used, but the disease increased, although checked a little and the bunches were all affected. This year, 1854, early in February, the house was washed with lime-water with a little sulphur in it, every available piece of plaster and brickwork, the flue included, being operated on; in June, the same suspicious spots of mildew made their appearance; in the evening, when the flue was just hot enough to bear the hand on it, it was done over with a mixture of sulphur and water, with a little lime in it, and again repeated at a week's end. The mildew entirely disappeared, and the Grapes ripened at the usual time, an excellent crop. The idea of washing the flue with sulphur was taken from an article in your volume for 1853, and I think it is an invaluable receipt. *D. S., Woodbridge, Suffolk. Gard. Chron., October* 14, 1854.

Publications Received.—*Proceedings of the California Academy of Sciences*, XIII, "The Escallonias in Golden Gate Park, San Francisco, California, with Descriptions of New Species;" and XIV, "Studies in the Flora of Lower California and Adjacent Islands," by Alice Eastwood, Curator, Department of Botany. Published by the Academy at San Francisco (no price).—*Journal of Genetics*, August, 1929, Vol. 21, No. 2, edited by R. C. Punnett, M.A., F.R.S. Cambridge University Press, Fetter Lane, E.C.4, price 15s. net.—*El Jardin Botanico Municipal de la Ciudad de Buenos Aires*, by Don Carlos L. Thays, Buenos Aires, Argentine.—*A Guide to the Flora of the Cape Peninsula*, by M. R. Levyns, pp. 284, with 199 illustrations, three in colour. Messrs. Juta and Co., Ltd., Cape Town, South Africa, price 15s. 6d.—*Garden Trees and Shrubs*, by Walter P. Wright, pp. 355, with seventy-four illustrations, twenty-four in colour; Messrs. George Allen and Unwin, Ltd., Museum Street, W.C.; second edition, price 15s. net.—*The Anatomy of Dessert*, by Edward A. Bunyard, pp. 134; Messrs. Dulau and Co., 32, Old Bond Street, W., price 10s, 6d. net.—*Index Kewensis*, Supplement Seven, pp. 260; Oxford University Press, price £3 15s. 0d.—*Report*, 1927-1928, of the Rothamsted Experimental Station, Harpenden, price 2s. 6d.—*Photography as an Aid to the Study of Plants and Plant Problems*, by William C. Davies; Banks Lecture, 1928; Messrs. Whitcombe and Tombs, Ltd., Wellington, N.Z.—*A Survey of the Soils and Fruit of the Wisbech Area*; Research Monograph No. 6 of the Ministry of Agriculture and Fisheries, pp. 71 with three maps, price 3s. 6d.—*Proceedings of the Academy of Natural Sciences of Philadelphia*, Vol. LXXX, 1928, pp. 640, illustrated, and with thirty-one plates; the Academy of Natural Sciences of Philadelphia (no price).—*Year Book of the Academy of Natural Sciences of Philadelphia*, 1928, pp. 90 and eleven plates; Philadelphia (no price).

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Oncidiums.—Specimens of the warm-house, bulbless Oncidiums, such as O. Lanceanum, O. carthaginense, and others, which have just passed out of flower may now require some attention at the roots. Those that require fresh compost or larger receptacles should be repotted now so that the roots may become established in the new compost before the short winter days set in. Clean, well-drained receptacles should be used, and a compost of chopped A.1. fibre and Sphagnum-moss pressed firmly among the roots, keeping the base of the plant just above the pot rim. Pieces of charcoal should be inserted as the work proceeds in order to ensure quick passage of the water, which is required in ample supplies during the growing season. During the winter months, after leaf-growth is complete, only small quantities of water at intervals are required at the roots to keep the leaves in a plump condition until growth commences again in the spring. At this season, these strong-leaved Oncidiums require all the available light and should be grown either suspended from the roof, or in a position near, but not in contact with, the roof glass. If the leaves of this or any other Orchid come into contact with the glass they will quickly become damaged. Oncidium Kramerianum and O. Papilio are warm-growing species, and specimens should produce flowers for a considerable time in succession; if the spikes are allowed to remain it is advisable to remove the scape after four flowers have opened, even on the strongest plants, or they become exhausted and require a very long time to become vigorous flowering plants again; overflowering is often the cause of great loss of plants. Other Oncidiums, such as the sweetly-scented O. tigrinum, O. varicosum and its varieties, O. Forbesii and others of the crispum type, thrive well in an intermediate house, in a position where plenty of light and air can reach the plants. Many are now producing flower scapes, and if slugs are troublesome will require some protection to keep the spikes safe. Various traps should be set and examined regularly—Lettuce-leaves, bran and cut pieces of Potato are good for this purpose—while the plants may be stood on inverted flower pots placed in a saucer of water. Bands of cotton-wool may also be used around the spikes, but these need frequent changing to keep a rough surface. Again, only strong, robust specimens should be allowed to carry flower spikes, as small plants soon become weakened. Plenty of moisture is required while the plants are growing and until the flowers have expanded. After the flowering period is over and growth is complete, only sufficient water is needed to keep the plants in a normal state. The sweetly-scented, small growing O. cheirophorum opens it flowers well in a position near the glass in the cool house, where the blooms will remain perfect for a long period.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Root-pruning.—The roots of trees may be divided into two groups, the strong main roots which serve as anchors to the trees, and hold them firmly in their positions against storms, and the fibrous, feeding roots which are to be found at the extremities of the smaller roots. The strong, main roots, if allowed to grow on unchecked, are generally conducive of rampant top-growth. To bring about fruitfulness in fruit trees, however, it is desirable that these thick roots should be checked in some way, and energy directed to the production of feeding roots. This is the first step towards the formation of fruit buds, flowers and, under favourable weather conditions, fruits. Various methods are employed to bring about this check to exuberant top growth. One of the principal, if not the oldest, is the judicious pruning or shortening of these thick roots. This operation, which is best carried out during October and November, is performed by making a trench eighteen inches wide and the same in depth at a distance corresponding to the spread of the branches. Gradually work away the soil towards the stem with a garden fork to well below the line of the lowest roots. Cut back all thick roots which appear to be travelling for a considerable distance from the tree, and secure all the fibrous feeding roots to be laid in again as the trench is refilled. In cutting back the strong roots the operator should stand in the trench with his back to the tree and, with a sharp knife, make all the cuts in an upward and outward direction. The roots resulting from this cutting will be formed on the upper side and nearer the surface soil. The aim of the cultivator should be to keep the feeding roots as near the surface as possible, where they may obtain air. This can be done by keeping the best feeding material near the surface, and also by top-dressing. A ball of soil, proportionate to the age and six of the tree, should be left intact to cause as little unnecessary check to the tree as possible. But in the case of strong-growing Pears, Plums and Apples on free or Crab stocks, a search should be made beneath the base of the tree for any tap-roots which may have penetrated straight down into the subsoil. These should be cut well back. In the case of young trees, it may be found more economical to lift and replant them, shortening any long roots while doing so. Only when the trees are making rampant growth is this necessary to bring them into a fruitful condition. With large trees, however, it is advisable to spread the operation of root pruning over two seasons by making a trench half-way round the tree the first season, and cutting the roots on that side, and leaving the other side until the following season. Return the same soil to the trench, making it quite firm about the roots, with their tips pointing upwards. If it is considered necessary, a few inches of fresh soil may be put on the surface as an encouragement to the roots to keep there; and a mulching of half-decayed manure to the outward spread of the roots will be found advantageous during the following spring and summer. Root pruning checks excessive growth, equalises the balance of strength between roots and branches, and brings the tree into a fruiting condition earlier than would be the case if left to itself.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Primula sinensis.—Where these plants have been grown in cold frames, the time has now arrived for them to be placed in an airy house where a minimum temperature of 50° can be maintained. These Primulas, when approaching their flowering stage, resent a cold, damp atmosphere, therefore it is wise to transfer them to a house and allow a little gentle heat to circulate through the pipes, and to admit air on all possible occasions. It is not wise to crowd the plants, and where the receptacles are well filled with roots they should be fed with liquid manure obtained from the cowshed; failing this, place cow manure in a bag and allow it to soak for several days before using the liquid. Weak soot-water makes an excellent change of food for this subject.

Euphorbia pulcherrima.—Perhaps better-known as Poinsettia, specimen plants should, by this date, have filled their receptacles with roots, and may now be given a light application of liquid manure, which should be placed in the house in which the plants are growing some hours previous to using it. These plants need some care when applying moisture to the roots, for although they should not be overwatered, it is imperative they should not suffer through lack of moisture, otherwise a loss of foliage may result. A temperature of 60° to 65° should be maintained at this stage of growth. Euphorbia fulgens requires much the same treatment as the above.

Francoa ramosa.—Plants of the Bridal Wreath which have passed out of flower, may need some attention with regards to dividing the roots and repotting. If the work is done now the plants should have time to form roots in the new compost before the shortest days arrive. Francoas require cool treatment at all times, and if the plants are stood in a cool house or frame where frost is excluded, such conditions should suit them. The compost should be of a light nature containing sufficient sharp sand to ensure a free passage of water. After potting, they should be kept close for a short time.

Regal Pelargoniums.—The Regal Pelargoniums which have been cut back and given a slight rest, should have most of the soil shaken from their roots and be repotted into the smallest receptacles that will accommodate them, and in which they may remain during the dull winter months, potting them on into their flowering pots so early as possible in the New Year. Cuttings that have been rooted recently should be potted on so soon as they have formed sufficient roots. After potting, they should be grown in a cool house near the roof-glass, and when roots are active again in the new soil the growths may be pinched back to induce a bushy growth. Aphides are very partial to these Pelargoniums, but if the plants are sprayed or dipped occasionally in Quassia extract they will be kept quite free from this pest.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

The Orchard House.—With the exception of a few late Plums and Pears, the trees in this house will now be clear of fruits, and the season being so favourable for ripening the wood, all the trees should have been removed to the open air. Peaches, Pears, Cherries, Plums and Apples which have ripened their wood should withstand any reasonable amount of frost, so long as they remain dormant, hence the advisability of giving them the fullest exposure. The trees should be protected against birds, and worms prevented from entering the pots, and when, later, placed in position, the spaces between the pots should be packed with Bracken or litter to prevent the soil drying out and the pots being broken by frost.

Potting.—Late trees may still be reduced and potted, picking out the old compost from among the roots with a pointed stick and repotting them in fresh compost. Roots being plentiful, they should fruit well after severe handling, provided they are not to be forced. Young trees which were lifted last autumn, pinched, and specially prepared for potting, may now be taken up and placed in pots varying from eight to ten inches in diameter. All stone fruits and Pears and Apples like fairly heavy calcareous loam, well supplemented with burnt earth, old lime rubble, bone-meal and soot in preference to animal manure of any kind. This compost can hardly be made too firm by ramming if the soil is in right condition. The trees should receive one good watering before being plunged in the open.

Early Pot Figs.—These being liable to injury from cold, they should be placed in a cold house or frost-proof shed when all the leaves have fallen. In this position, if the pots are protected, they may be left for months without water and suffer no injury.

Pot Vines.—The vines in pots intended for starting at the end of November may now be shortened back to their proper length and placed in a position where they can be kept quite cool and sheltered from heavy rains. Any loose surface soil may be removed and when the soil is moist they may be top-dressed with good loam well enriched with bone-meal.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Tree Paeonies.—The Tree Paeonies are rather neglected plants, yet they are quite hardy, although the early young growths are often cut by late spring frosts. Their proper place is in sheltered nooks in the shrubbery or pleasure grounds, where their young, brightly-coloured leaves and gorgeous blooms can be seen to advantage in early spring. The same remarks as to the preparation of the soil apply to these as to the herbaceous sorts, the Moutan Paeonies being even grosser feeders than the herbaceous sorts. Being of slow growth in their young state, patience is required until they become a reasonable size, when they will flower freely, provided the buds escape damage by late frosts.

Routine Work.—Owing to falling leaves, worm casts and decaying flowers, it is now difficult to maintain neatness in ornamental grounds, but as little enjoyment can be derived from an untidy garden, every effort should be made to do so while the fine weather continues. The bright weather we have had during the past few weeks has infused a degree of brightness into the flower beds that has not been exceeded the whole season, and endeavours should be made to maintain this so long as possible. Tender plants that have been used for bedding and which are to be preserved for stock for another year, and which cannot yet be lifted without spoiling the general effect of the flower garden, should be covered every night with some light protecting material. The propagation of plants for use in the flower garden for another year still requires attention. The more tender subjects have been attended to in this respect before this, and the young plants ought now to be in safe quarters, as frost may be expected at any time. Cuttings of such hardy bedding subjects as Calceolarias, Violas and Pentstemons will root freely and winter well—indeed, best—if inserted in a cold frame.

Rambler Roses.—If not already done, cut out all shoots of Rambler Roses that have flowered during the season if there is sufficient young shoots of the current year's growth to furnish the plants for next season, if not, retain the best of the old growths that have flowered this season, and prune back the lateral growths to two or three buds in spring. Tie in all shoots securely now, to prevent damage by autumn and winter storms. Long shoots of dwarf or standard Roses may also be shortened to half their length during the month, to ensure the plants against damage during stormy weather. Many varieties of Roses may be increased readily from cuttings of the current year's growth. These should be taken off with a heel and inserted in a prepared bed of sandy soil, preferable at the base of a wall facing north, where they ought to remain for a year.

Carnations.—Border Carnations that were layered late and were not ready for planting in their permanent places during September, should now be severed from the parent plant and potted either singly into three inch pots or two in a larger pot. A compost that suits them is four parts good, sweet, maiden loam, one part leaf-soil, and one part sharp sand. Place them in a cold frame, water, and shade for a week until they have made some fresh roots, afterwards admitting abundance of air on every favourable occasion.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

French Beans.—Where these are growing in pits or frames they must receive careful attention if satisfactory results are to be obtained. Ventilate the house or frame on bright days, closing it early in the afternoon. Syringe the plants overhead and maintain a growing temperature; support the plants by means of small canes in preference to Birch twigs.

Asparagus.—So soon as the foliage has died down, clean the Asparagus beds thoroughly before applying a mulch of well-decayed farmyard manure or, if that is not available, a mixture of decaying grass and leaves.

Cabbages.—If the spring Cabbages have not been planted, no time should be lost in attending to this work, so as to give them an opportunity to become established before the cold weather sets in. Dust around the plants with soot, lime or spent carbide, to ward off snails, which are troublesome during wet weather.

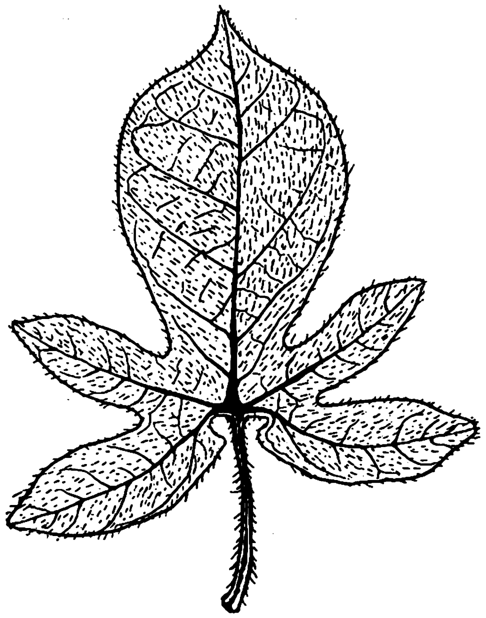

FIG. 135.—JAPANESE MORNING GLORY; LEAF OF THE SEMIBA STRAIN.

(see p. 282).

Tomatos.—Late plants in pots that have been growing outside should now be taken indoors. If four or five trusses of fruits have set pinch out the points of growth to encourage the fruits to swell, and give an application of Clay's fertiliser.

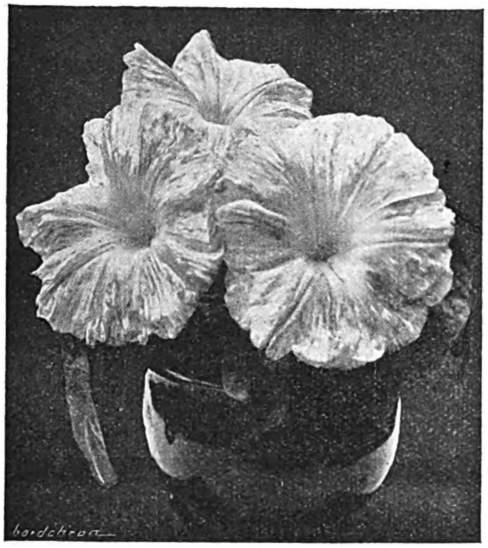

FIG. 136.—JAPANESE MORNING GLORY SEIHA.

An example of the Bonzo-tsukuri training.

(see p. 283).

Winter Spinach.—During dry weather, this crop should be encouraged by frequent stirring of the surface soil between the lines, and make sure the plants are not too close in the rows.

Peas.—If these have finished cropping, the beds may be cleared and the ground dug and planted with Lettuces and Endive, which should prove useful during the early spring months. Late Peas are filling up well and should be assisted with applications of liquid manure every week.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Onions.—Bulbs in process of drying should be looked over occasionally, and all those in a fit state picked out and stored for the winter. It matters little whether they are suspended in bunches or strings, or laid out in a dry loft, so long as dry, cool and airy conditions are maintained. Under such conditions a touch of frost will do no harm; heated structures for storing Onions in should be avoided, as in such premature growth is sure to be encouraged. Under proper conditions transplanted Onions should keep until February, and those sown *in situ* until March or April. Only the loose skins should be removed from the bulbs, along with the roots and part of the tops, as over-cleaning is worse than too little. Any decaying bulbs should be removed directly they are noticed.

Root Crops.—These have now reached maturity, and a dry day should be taken advantage of to have them stored. Carrots, in most cases, may be drawn from the ground without injury, but Beet should be lifted more carefully or bleeding may take place. A spade or digging fork should be used and every care exercised that no roots are fractured in the process. Any soil adhering should be scraped off with the back of a knife or a large wooden label, and the tops removed well above the crown. After an hour or two to dry in the open air they may be stored in a frost-proof shed and covered with fairly dry sand. The cooler the store is kept the better the roots will keep, provided frost is excluded. Salsify and Scorzonera should be treated in like manner, but Parsnips are much better if lifted from the ground as required; when frost threatens, a quantity should be lifted for use until the ground is workable again. Late Potatos should be lifted and stored as severe frosts may be experienced at any time now. Choose a dry day for this work, and pick out all small and diseased tubers as lifting proceeds, leaving the ware Potatos to dry for a few hours, if possible. The tubers may be stored in a cool frost-proof shed if air and light can be kept from them, but if in large quantity, a pit is much the best and safest place for them.

Watering.—As the houses are filled with plants from frames and out-of-doors, extreme care should be taken in watering from now onwards. Soft-textured plants, such as Primulas of all kinds, Cyclamens, Cinerarias, etc., should never be allowed to become very dry at the roots, and when water is given it should be in sufficient quantity to wet the ball of soil completely. All watering should be done before mid-day, and as the days shorten, care should be taken to have no superfluous moisture about the house. A little fire-heat may be employed while the house is open, to dry it up, but, other than during frost, the use of fire heat should be avoided, and a little top air admitted, according to the weather, even during the night. Young growing plants of Schizanthus, Clarkia or other annuals should be sprinkled gently early in the day, when the weather is fine, but the foliage should be kept dry during the night. These and all growing plants should be kept close to the glass, shelves being ideal for this purpose.

Digging and Trenching.—As ground is cleared of crops, plans for the succeeding crop should be made, and the ground treated accordingly. One can hardly go wrong in working the ground deeply for all vegetable crops, but in the application of manure it is different. Where the subsoil is heavy, double digging should be practised, working in opening material of any description at hand, but if sufficient depth of good soil is found, trench by all means. For next year's Onion crop the ground should receive a heavy coating of cow or horse manure, according to the texture of the soil, and if sufficient quantity is available, both spits may be manured; if not, place the manure in the top spit, leaving the surface rough or ridged for the winter.

INDOOR PLANTS.

BRUNSVIGIA JOSEPHINAE.

(The Candelabra Plant.)

Having read with interest various notes in *The Gardeners' Chronicle* on this plant, the following information regarding its cultivation, etc. is written in the hope that it may be of value to those who have experienced difficulty in persuading the bulbs to produce flower spikes. In 1926, six bulbs were secured from a consignment imported direct from South Africa. Strong, healthy foliage was produced in each season of growth, but despite careful attention to watering, feeding and resting, no spikes were produced in 1927 or 1928.

During the autumn and winter of 1928-29, the foliage produced was again exceptionally good, no doubt due to the weekly applications of liquid manure which the plants received. The plants had been growing in a temperature of 60° to 65°, but when the foliage commenced to turn yellow, they were removed to a cooler house where the temperature was 50° to 55°, and placed on a high shelf, about three feet from the glass. From this time onward no water was given.

The first spike appeared during the third week of June, and eventually produced its red, Amaryllis-like flowers, about three weeks later. Four out of the other five bulbs flowered in succession, the last spike being at its best at the end of August.

The main stems of the flower spikes varied from twenty inches to twenty-four inches in height, and the pedicels, carrying single flowers, were from twelve inches to fifteen inches in length. The best plant carried forty-one blooms and was a splendid specimen; it received an Award of Merit at the Royal Welsh Show, held in Cardiff, on August 7, 8 and 9, of this year.

Seed-pods have formed, and some of the seeds appear to be quite sound. Photographs are enclosed of one of the flowering plants, and also of the best specimen, showing the seed-pods.

The grower who has been so successful with this interesting plant is Mr. H. Watkins, gardener to Mrs. Folland, Llynderwi, Blackpill, Swansea, who is well-known in this district as a grower of vegetables for exhibition. *Glam.*

[The photographs were good and portrayed fine plants, but are not reproduced as illustrations have appeared recently.—Eds.].

ARISTOLOCHIA BRASILIENSIS.

This very singular plant is not easily described and perhaps one cannot do better than quote G. Nicholson, who states (under its synonym of A. ornithocephala): "This species may be said to have the head of a hawk and the beak of a heron, with the wattles of a Spanish fowl, which, however, are grey, netted with brown; head of the same colour, veined; and the beak grey."

As I recently saw this plant, draping the roof of a corridor, with its handsome, ample foliage and with numerous flowers—large and grotesque—it is indeed a quaint subject, handsome and pregnant with interest; the cordate, almost reniform, obtuse leaves are quite ornamental and the flowers are produced freely and for a long period during summer and autumn.

A tropical species, the plant thrives in an ordinary warm greenhouse, and like all its family, it loves sunshine, plenty of moisture when growing, and a rich soil. During the winter just sufficient water should be given to prevent the soil from becoming dust-dry, and hard pruning should closely follow the flowering period.

Planted out or grown in a large pot, this weird Aristolochia should invest a structure with interest and with beauty of a somewhat quaint order. A. brasiliensis was introduced from Brazil in 1838. *Ralph E. Arnold.*

LABELLING EXHIBITS AT SHOWS.

If it be permitted to a mere amateur to criticise a show so excellent as that held at the new hall of the R.H.S. on October 2 and 3, there is much that he would like to write upon one aspect of it—namely, the labelling of exhibits.

All the exhibitors deserve praise for the interesting and beautiful collections shown, but many of them cannot be congratulated upon the care with which their labels had been prepared. Apart from the question of following the nomenclature of the Kew *Hand Lists* (upon which they may have their own views), there surely can be no excuse for the carelessness which led to the following labels being put up—and these are just a few noted at random, without any determined search for mistakes :—

Taxus fastigata aurea,
Thuya Lobbi,
Hippophae rhamoides,
Berberis Wilsonii,
Berberis Thumbergi,
Berberis staphina,
Berberis vulglis purpurea,
Pyrus hibrida,
Pyrus tungoides transitoria, and
Liriodendron tulipiferum.

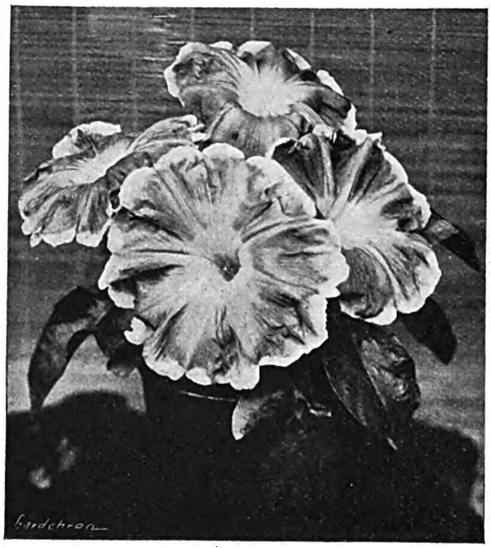

FIG. 137.—JAPANESE MORNING GLORY.
Awarded First Prize at the Nagoya Morning Glory Society's Show.
(see p. 283).

The cream of them all, however, was the label "Viburnum opulus sterile" attached to a glorious clump of fruiting branches of Viburnum Opulus! In justice to the firm responsible, however, it must be stated that the label was at once removed on the mistake being pointed out to them, but as the show had then been open six hours, there is no knowing how many people had been misled.

Generally, the legibility of the labels left a good deal to be desired. Some firms, it is true, employed labels which were beyond reproach for clearness of lettering and for being written in waterproof ink which did not run or smudge as a result of watering. Others, however, had used ordinary ink, and their labels were well-nigh unreadable on the second day, especially where, as was too often the case, the lettering was cursive and not in capital letters. Again, some firms' labels were inscribed in lettering so minute as to be difficult to read at three feet, even to a person of normal sight.

In one case labels were in very plain and bold writing—but in pencil, not ink. As a consequence, they gave rather an unfinished look to the whole exhibit. One particularly interesting exhibit of uncommon shrubs had extremely neat labels, done on a typewriter; but, unfortunately, the ink had run badly after watering, which quite spoilt their pristine beauty.

As it is, plant nomenclature is a big enough problem to the amateur without its being made more difficult by carelessly-prepared labels at shows, and by the attempts of some exhibitors to ruin his eyesight with their curious lettering! It is, therefore, suggested to the Royal Horticultural Society, in all seriousness, that they insist that labels used at shows under their jurisdiction be written in characters easily legible, and in an ink which will not be liable to smudge when the plants are watered. After all, waterproof ink costs very little more than blue-black! *R. C. B. G.*

JAPANESE MORNING GLORIES.

The Japanese Morning Glory, or Asagao, is one of the most popular flowers in our country where Ipomoea hederacea (syn. Pharbitis Nil) was introduced, in small, simple-flowered form, from China some thousand years ago, for medicinal purposes. Since then it has been greatly improved as an ornamental flower and is much appreciated. There are many old poems composed in praise of the Asagao. In the Bunka Era (1804-1817) the Morning Glories became extremely fashionable all over Japan. "Morning Glory fever" spread to all the classes, from the aristocracy and lords to the petty merchants and workmen, each man striving to outdo his neighbour in meritorious varieties and skill of culture. Certainly this "fever" helped to develop the Morning Glories and their culture. But, consequently, the "fever" had attendant ills, as in the Tulip mania in Holland, and the feudal government often cautioned people. In those days and afterwards, the double-flowering varieties, which have considerable interest to the pathologist and others, aroused much attention, and many curious and interesting double forms were raised. They are not now so popular as the large-flowering, single varieties. Thirty or so years ago, the large-flowered, single varieties became very fashionable in Nagoya, where the modern methods of culture and many varieties grown in these days owe much to the enthusiasts in the city. The Semiba strain, which has the largest flowers, originated among them. This epoch-making strain soon overshadowed all others, as it provided vivid colours, selfs or stripes, with a white, broad throat and five-lobed leaves (Fig. 135). The Semiba strain is broadly divided in two groups, namely, those with green leaves and those with yellowish leaves; the former is more vigorous than the other, but the latter is easier to cultivate because it is moderate in growth. Chidoriba, Kuwagataba and many other strains are not so much cultivated now as the superior Semiba strain has taken their place.

There are three well-known styles of training, namely Bonyo-tsukuri, Ando-tsukuri and the style invented among the members of Kyoto-Asagao-Kenkyukai. The first and third are now most popular among lovers of Morning Glories.

Bonya-tsukuri training was invented in Nagoya many years ago and developed by the members of Nagoya Asagao Kai, a leading Morning Glory Society. The methods of culture and training are as follow :—Generally, the seeds are sown between May 5 and 8, in a pan four to five inches in depth, filled with sifted soil that has been used for Chrysanthemum culture; this is surfaced with one-third-of-an-inch of fine, pure sand. The early sowing often fails because of the cold weather. The seeds should be sown one-third-of-an-inch deep, and they will germinate in four to six days, and the day after germination takes place the cotyledons should expand, and that is the time to prick out the seedlings, placing them singly in the flowering pans. Selection is very essential; those having roundish cotyledons with rounded apices should be retained. The potting compost is a mixture of three parts loam, two parts leaf-mould and five parts sand, the last being essential to ensure the free passage of water; every kind of manure should be avoided in the compost, as it damages the root and possibly the cotyledons soon fall—the enthusiasts exercise great care to retain the cotyledons until flowering time.

The potted plants should be exposed to the sun immediately after watering; those that wither are not worthy to be grown; during all stages of their cultivation they should be given sunny, airy conditions, with ample supplies of water, and the resulting growth should be firm and sturdy, which is very important when dealing with the Asagao. If the plants become too firm and sturdy, then an extract made by boiling fishes (avoiding the fatty ones) should be given. Artificial manures are not recommended for the Asagao.

When the Asagao, a climber by nature, has attained a length of several inches and carries seven or eight leaves, and the lower two buds have formed shoots of about two-thirds-of-an-inch in length, the points should be removed, allowing one leaf to remain. This is called the nutriment-absorbing leaf. By stopping the shoots at different times the flowering season is lengthened. Generally, at each axil of the shoot, beginning at the second axil, a flower bud forms. Ten or so days after the first stopping, four leaves are retained on each shoot and the rest are cut off, or five leaves may be allowed to remain provided the flower bud, which forms in the axil of the second leaf, is removed. In the latter case, larger blooms may be expected; in each case the axillary bud of the top leaf should be allowed to develop until the flower bud has attained a moderate size, when the latter should be rubbed off, but the petiole retained. Manuring follows the second stopping; we use a manure called Tamagoe—eight parts of pulverised Rape-cake and two parts pulverised dried bonito are mixed, adding a small quantity of water, and kneaded into pellets as large as a finger's end. That is kept in a tin box until used. Two Tamagoe should be pushed in the pan, just below the surface of the soil. After applying Tamagoe, liquid manure should be given, according to the conditions of growth. The liquid manure is prepared as follows:—In a large bottle or pot, pour twenty litres of water and two litres of Rape-cake; this should be kept sealed up tightly until used. One part of this manure mixed with twelve parts of water should be given every other day at four o'clock in the afternoon.

The first flowers should be expected in two months after seed-sowing. When four flowers on a plant are finished, both shoots should be cut off, retaining the first bud which is formed in the axil of the first leaf on the shoot. Each bud remaining on the shoots soon grows and should be cut back in the same way as already mentioned, retaining four or five leaves. By repeating this method, generally four times, sixteen very large flowers should be produced on each plant. Blooms less than seven inches in diameter are, by the Bonyo-tsukuri training, regarded as unworthy of admiration, but the striped flowers are considered good if they are six-and-a-half inches in diameter.

In the early stages of their cultivation watering once a day is enough, but in mid-summer water should be given twice a day—morning and afternoon—and the soil always should be surfaced thinly with Sphagnum-moss.

The enthusiasts exercise much patience in endeavouring to secure flower buds within the edge of the pan. The photographs (Figs. 136 and 137) show the typical styles of the Bonyo-tsukuri training as practised by well-known experts.

A style now known as the Kyoto-Asagao-Kenkyukai-Shiki was first invented by Mr. Shigejiro Okuda some twenty years ago, and improved by Mr. Eisaburo Gibe, whose enthusiasm and cleverness made this style one of the most popular. Desiring several flowers on a plant at the same time, Mr. S. Okuda, the Hon. Secretary of the Kyoto Morning Glory Society, invented the style, which may be called an improvement on the preceding. The soil recommended is a mixture of five parts leaf-mould, five parts loam and two parts of sand of the size of a large Cyclamen seed. Straw-ash should be added in small quantity. The seeds are sown in the way already mentioned, but at two or three different times, beginning at about May 5, and then once a week afterwards. The very day, or the day after, germination takes place, the seedlings should be planted (ascertaining whether they are true to the colour by means of the young stems) in their flowering pots, not earlier than four o'clock in the afternoon. The first stopping is done when the plants produce eight or nine leaves, retaining six leaves; while if the shoots in the axils of the first and second leaves are vigorous, retain four leaves. The upper leaf in both methods is the nutriment leaf, and its axillary bud is rubbed off. The plant produces three shoots, which should be cut back when they have five or six leaves, retaining two leaves; thus, altogether, six leaves are retained and produce six shoots from their axils, and these may be reduced to three, four or five according to the form one wishes. Retain three or four flowering buds and the top leaf on each shoot, and remove the rest. These shoots should be cut back to the first bud when flowering is finished. The new buds soon develop when the method of stopping just mentioned should be repeated. In this way the second period of flowering is secured. The manures are prepared and used as follow:—Ten parts Rape-cake, two parts Rice-bran, and one part straw-ash are mixed, adding a small quantity of water, and kept in a tin box until required for use. The manure is used when the first stopping is finished, giving a small quantity just under the surface of the soil, but not near the stem. More is applied, according to the condition of the plant, when the second stopping and also the stopping of flowering shoots is finished. When the flower buds show colour very slightly the supply of liquid manure should be stopped. In all stages of their cultivation, rubbing off the unnecessary buds should not be neglected.

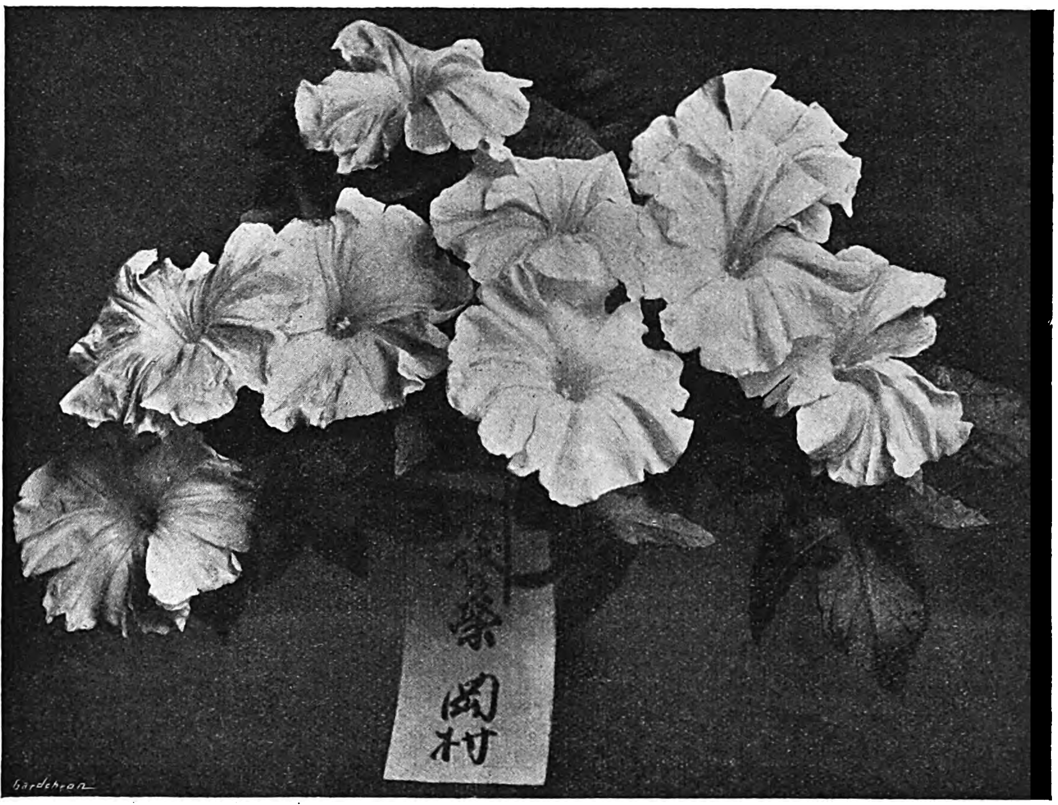

FIG. 138.—JAPANESE MORNING GLORY MIYO-NO-SAKAE.

Awarded First Prize at the Kyoto Morning Glory Society's Show.

The Morning Glory Miyo-no-Sakae (Fig. 138), grown by Mr. Kisaburu Okamura, shows the Kyoto Morning Glory Society's style of culture.

When the large blooms have been admired in their several periods, according to the number of stoppings, the plants are placed in a bed or retained in their pots or pans for seeding. Several tall Bamboo stems are used, and the new shoots allowed to climb up them. These give the blooms from which seeds are saved.

The following are a few of the best varieties cultivated:—Kato-no-Homare, white, beautifully striped with clear crimson, one of the very best; Genroku-Bijin, soft pink, broadly bordered with white; Miyo-no-Sakae (Fig. 138), crimson, streaked with white; Okina-no-Tomo, white, striped with brown; Kumoi, ultramarine; Kwa-O, Cherry-colour, bordered with white; Haku-O, pure white; Uji-no-Tsuki, clear light brown; Fujibakama, lilac; Hinotsukasa, vivid crimson; Ide-no-Tsuki, yellow; and Seiha (Fig. 136), light blue, streaked with white—one of the greatest favourites.

The Ando-tsukuri method of training is popular in Osaka. In the two styles already indicated the climbing nature of the Asagao is suppressed, but in the Ando-tsukuri training the climbing habit is appreciated. Several Bamboo stems, three feet to four feet tall, are placed in each pot and fastened with three wire rings; the plants climb these supports and are stopped when ten to fifteen flower buds have formed. Cutting back the shoots is repeated in due course. Large blooms are not expected, and cultivation is much easier by this method than by the two described.

In our gardens the Asagao is also cultivated as an ornamental climber, supported by Bamboos.

My best thanks are due to Mr. Shigejiro Okuda, of Kyoto, and Mr. Suzuki Yusoan, of Nagoya, well-known experts, for much information on the culture of the Asagao. *K. Yashiroda, Tonosho-kyoku, Kagawaken, Japan.*

TREES AND SHRUBS.

A DWARF GENISTA CINEREA.

Under cultivation, the above species grows rapidly and ultimately attains a height of eight to ten feet, although in a wild state it varies from sixteen inches to two feet eight inches. It is a native of France where it grows on the sides of calcareous mountains. It also inhabits the Iberian Peninsula, Italy and North Africa.

Some time ago I had a branch of this Genista from Miss Willmott, Warley Place, who said it did not exceed three or four feet in height, although of some considerable size. Judging from the branch, it looked aged, for the twigs were densely crowded, and thickly covered with their yellow flowers. These are not borne in racemes as in many of this group of Leguminosae, but in axillary clusters of two to four along the greater part of the length of the twigs. Possibly this may be a dwarf form of the species, which is not unlikely, when the nature of the habitats of the wild plant is considered. The value of the species in gardens is enhanced by its flowering during June and July, after most of its congeners are over. *J. F.*

BERBERIDOPSIS CORALLINA.

Berberidopsis corallina is certainly one of the most beautiful flowering shrubs which have yet been introduced from Chili; moreover, this plant has attracted a considerable amount of interest in recent years, since it has been planted so frequently as to test its hardiness under widely different conditions, unfortunately, only too often with disastrous results.

The name is distinct and well-chosen, indicating its similarity to some of the Barberries, and giving some idea of the colour of the flowers. In fact, Berberidopsis corallina is the only plant of its genus, and may be so closely allied to Berberis as to necessitate a change of name at some future date, a fate which has overtaken so many garden plants in the past. At present it is placed in the family Bixaceae, together with, among others, the Azaras. Incidentally, both these genera are Chilian, and both are present in Valdivia, from which province the subject of this note was introduced nearly seventy years ago.

The growth of B. corallina is inclined to be rambling, the stems being somewhat thin and wiry, and sparsely set with thick, leathery, ovate or heart-shaped, alternate leaves. These leaves are provided with sharp marginal spines and equally sharp, acute apices; they are one-and-a-half inch to three inches long (occasionally longer), and three-quarters-of-an-inch to two inches broad at the base. The flowers are borne in July, August and September, in clusters or singly, in the axils of the leaves near the ends of the long and sometimes contorted stems. The individual flowers are coral-red in colour, globose in shape, and about one-third to one-half inch in diameter, with a double row of segments, varying in number, but the outer ones lying almost flat, while the inner segments are incurved over the stamens and style. Each bloom hangs pendant from a stalk one inch to two inches long and of the same colour as the flower.

Unfortunately, B. corallina, like so many Chilian plants, lacks absolute hardiness, but it can be grown on a south or south-west wall, or in a cool glasshouse. It appears at its best against a grey stone wall, and should not be planted with a background of red brick where the glossy green leaves and bright red flowers do not show to advantage. The species does, however, occasionally become thin, losing the lower leaves, and such specimens may be induced to make more growth by judicious pruning, but this should not be overdone and, in fact, should be avoided if possible, as the plant is naturally a straggly, woodland rambler, climbing by means of its spiny foliage. As a rock garden plant in very mild localities, B. corallina is very beautiful, and it should be allowed to ramble at will down some great rock where there is plenty of room for the long stems. The writer has even seen B. corallina in the southern counties growing (but not luxuriantly) over a large boulder facing due north; the situation was completely sheltered from the cold north-easterly winds, and it flowered each year, but not profusely. It is not exacting as regards soil, provided the latter is well-drained, and although it will not tolerate lime, peat is not essential when the plant has reached maturity. For that matter, it is doubtful if peat is necessary at any stage, although a peaty compost helps to induce a compact ball of roots in readiness for planting out, owing to its own fibrous nature.

B. corallina may be propagated by layers in autumn, or by cuttings of young wood in spring. Propagation may also be effected by seeds, but the latter are not freely produced in this country. *L. B. C.*

ESCALLONIA IVEYI.

Among the more recent of hybrid Escallonias, the subject of this note deserves a prominent position. A young specimen of some three or four feet in height proved its mettle here last winter by surviving the very severe frost without injury, and it has grown with that freedom which suggests a good and vigorous constitution.

E. Iveyi is believed to be a natural hybrid between E. macrantha and E. montevidensis, and it certainly looks like perpetuating the best qualities of both its parents. The large and leathery, dark green, glossy leaves suggest those of E. macrantha, as does the somewhat heavy, bushy habit of growth, but the flowers, instead of being red, are pure white with a stain of crimson at the base of the corollas which imparts a rosy flush to the truss. Individually, the blooms are about half-an-inch across; they have the waxen texture of those of E. macrantha, and are borne in bold, outstanding panicles. These blooms are later than those of the last-named species and earlier than those of E. montevidensis, which means that we have in E. Iveyi a shrub that should make its mark as an evergreen flowering shrub for the latter half of summer.

E. Iveyi promises to be hardier than either of its parents, and it should prove to be a good wall plant, even for those who dare not risk Escallonias in the open. This interesting novelty made its first appearance at Chelsea in 1926, when it was granted an Award of Merit. *J.*

POTENTILLA FRUTICOSA VAR. MANDSHURICA.

Farrer, in the appendix of his *English Rock Garden*, gives an attractive vision of what we might expect from the forms of Potentilla fruticosa from Tibet. Some of these are already in commerce, but he tells that there are shades of cream, yellow, amber and orange which are still to be offered to tempt us to add them to our gardens. The various sizes and habits, also, which these plants appear to assume will give us varieties dissimilar to those we have at present, while the hybridiser will, no doubt, get to work to raise varieties of this most valuable shrub.

One of the best and most distinct of the forms of P. fruticosa at present in cultivation, and one, too, which will not easily be ousted, when once in a garden, because of its beauty, is the variety mandshurica, which is stated to be not uncommon in the semi-arid valleys of western Szechuan. It has received the hall-mark of quality from the Royal Horticultural Society by the Award of Merit given to it, and I make bold to state that no one who has grown it will cavil at this distinction.

It is, perhaps, the most distinct form of P. fruticosa if we limit our choice to the smaller forms best suited for the rock garden, of which there are many. It is an ideal rock garden plant, and forms close carpets of lovely, silvery leaves thickly studded with wonderfully large white flowers resembling those of P. f. var. Veitchii, but looking delightful among the silver foliage and in the surroundings supplied by the rock garden. It is delightful trailing over a bank or a boulder or covering a level terrace, and its apparent indifference to the ordeals through which it passes in a climate such as ours tells convincingly of its value.

P. f. var. mandshurica is a real gem and does not seem to resent the wettest winter we are likely to have or the coldest one on record. It may be grown, too, from seeds or cuttings. It blooms for several months during the summer, and far into latest autumn it dares the frosts of the season and gives delight by its snowy blooms. *S. Arnott.*

BULB GARDEN.

COLCHICUM VARIEGATUM.

The finest of the tessellated Colchicums so far known is C. Sibthorpii, but, unfortunately, it does not appear to be so hardy as we would like, and, to the best of my knowledge, it is not at present procurable from the trade. I had it at one time but lost it during a winter of little more than average severity. It has not been offered by any of the larger bulb dealers for some years. It is a great beauty, with large flowers of rather pale lilac or purple, regularly tessellated by darker markings. It is C. latifolium, of Sibthorp and Smith, *Fl. Graeca*, Fig. 350. According to Mr. Baker in *The Colchicaeae and Abberant Tribes of Liliaceae*, the form × variegatum, of Sieber, is a variety, but is not C. variegatum of Linnaeus, which is the subject of this note.

This is not so attractive as C. Sibthorpii, but but is very distinctly tessellated and the colouring is much deeper. It was known to Parkinson, and appears in his *Paradisus*, 155, 156, Fig. 5, under the name of C. Fritillaricum Chiense. In the *Botanical Magazine* it was called by Hooker, fil. C. Parkinsoni, and was figured in t. 6,090 of that work. The name of Linnaeus C. variegatum has priority, and according to Baker, this Colchicum is figured under that name in the *Botanical Magazine*, t. 1,028, and this name is supported by other authorities. It has also been known in gardens as C. chionense. It is rather a small-flowered species compared with such Meadow Saffrons as C. Bornmuellerii or C. speciosum, and is of moderate height, and when in bloom in autumn a small clump looks exceedingly well, with the dark flowers with sharp-pointed segments. From two to three flowers are produced by one corm. The leaves are produced in spring and are more pointed than those of C. autumnale. One advantage of this Colchicum is the comparative short tube, which enables the flower to withstand stormy weather without suffering so much as do those with long tubes. I have found C. variegatum much hardier than C. Sibthorpii. It comes from Asia Minor and the islands of the Levant.

July is probably the best month in which to plant the corms, which are then at rest, but I have planted them much later and also in spring, and, with care, they did not appear to suffer from removal at an unpropitious season. This Colchicum was shown as C. Parkinsonii at the recent Autumn Show of the R.H.S. *S. A.*

HARDY FLOWER BORDER.

EUPHORBIA SIKKIMENSIS.

This is a very beautiful Spurge with large heads of brightly-coloured blossoms, individually of good size; the deep, butter-yellow is slightly, almost elusively, suffused with green, an added charm to a very fine plant.

The young growths and stems are vivid scarlet, and so this plant is a notable ornament of the hardy flower border for a goodly portion of the year; it thrives in a good ordinary soil and is palpably a good dry-weather plant. A mingling of this and Salvia turkestanica was, a short time ago, a fine feature; quietly coloured, perhaps, but undeniably beautiful. I know little of the origin of this species, but I believe Mr. Elwes collected seeds of it in the Himalayas. *Ralph E. Arnold.*

ALPINE GARDEN.

ERODIUM MACRADENIUM.

The Erodiums are among the most valuable of our rock plants, and fill a place all their own. Although they are nearly allied to the Geraniums and Pelargoniums, they have yet about them a grace and elegance which we cannot find in these other indispensable plants. They are of the highest importance for the sunnier places in the rock garden, and thrive well in similar positions in the moraine. Apart from their charming flowers, almost all of them have foliage of delicate Fern-like aspect, and even when out of bloom are decidedly fascinating.

Of the numerous species, many of which are in cultivation, E. macradenium is one of the best for general culture in the rock garden. Although a native of the high mountains of the Pyrenees, it does not absolutely require lime in our gardens, and the writer is at present cultivating it in a lime-free soil. In this medium it is apparently happy, and has been in flower practically all the summer, and even in these autumn days bears freely its charming blooms. Farrer distinguishes it from E. Choulletianum by its being "green and smooth, glandless and bald, except sometimes for a few spreading hairs." Another point of difference is in the flowers which, in the case of E. Choulletianum, are "reported violet and equal-petalled," while E. macradenium has the upper petals smaller than the others and their paleness is emphasised by the presence of black blotches which add much to the charm of the blooms. The foliage is aromatic, which adds to the interest of this Heron's Bill.

E. macradenium grows only four or six inches high and looks well on the level, from a chink in the rock garden, or in the moraine; while it does not absolutely require lime, some may be added to the soil if convenient to do so. It is propagated by seeds or cuttings.

Its date of introduction is given as 1856. It is figured in the *Botanical Magazine*, t. 4,554, and its colour is given in various works of reference as "purple," while it is stated to be synonymous with E. glandulosum, which is evidently an error. E. macradenium is hardy with me, and survived last winter. *Dumfries.*

CYANANTHUS.

There are not many of these charming Campanulads at present in cultivation, but what few we have are well worth growing and one or two of them are so supremely lovely as to be worth every effort needed to make them thoroughly at home.

C. Delavayi I do not find mentioned in any of my books; it is a hairy little plant of trailing growth, frequently set at the ends of the shoots with rather pale blue stars; it is not one of the most beautiful, but is well worth a place in the moraine, either limestone or granite, but care should be taken to protect it from the ubiquitous slug, which pursues this, as well as the other Cyananthus species, with an unholy zest.

C. lobatus is a gem. From a fat, central crown it sends forth radiating and trailing shoots, thickly set with small, white-haired leaves, and each terminating in due season in a single, large blue flower, similar to a Periwinkle in shape and colour. The calyx is large and baggy, and should be split open after the glories of the flower have faded, as it tends to hold moisture and rot the seeds before they are properly set. C. incanus is similar in all its parts to C. lobatus, but frailer, and with rather more starry flowers, and the calyx has tawny fur, rather than the stiffer bristles of C. lobatus.

I find C. Forrestii, C. pedunculatus, C. integer and C. microphyllus all lauded by Farrer in *The English Rock Garden*, but, alas, I know them not, so will pass them by until I am fortunate enough to have plants from which to describe them.

C. incanus var. leiocalyx I have just found, to my horror, according to Farrer, should be yellow! This sounds too good ever to be true who ever dreamt of a yellow Cyananthus? At any rate, the plant I have growing under this name is a jewel beyond price, almost the best of this lovely race. In habit it is similar to C. incanus, but much stronger, for the sturdy, trailing stems flop afield to a distance of nine inches or so, and the terminal flowers are a glory of deep, deep violet blue, with the loveliest imaginable beard of delicate violet hairs in the throat.

The glory and pride of the Cyananthus race, I have left until last to describe; as yet it has no name, being known merely as K.W. Sp., and if Captain Kingdon Ward never introduced another plant, he could own his laurels well-earned by this incomparable beauty. It is larger and stronger in all its parts than any of the foregoing, the leaves and stems are perfectly glabrous and a soft green in colour, but the flowers—I feel the need of Farrer's eloquence fittingly to do them justice. Fully an inch-and-a-half to two inches across, these purest violet-blue glories are borne in solitary state, each at the end of a far-trailing shoot; the petals are more waxy in texture than most, and seem, as they glisten in the light, almost to radiate the perfect colour.

All these species and varieties are of the easiest culture, provided a few broad rules be followed. They strongly object to too much wet during the winter months, as do most of the alpines from the high mountains of India and China; I find it advisable to spare them a pane of glass during the wettest months, thus at least ensuring plenty of flowers the following season. They all flower about July-August, and most of them are now sending forth a second crop of flowers, smaller than the first, but still lovely; this is no doubt due to the abnormal season, as they are usually thinking of retiring for a well-earned winter's rest by this time (end of September).

Propagation is simple, either seeds or cuttings providing a good method. Soft tips inserted before flowering commences make strong plants the same year, but care should be taken, as they damp-off readily, so they should not be kept too close; I find they root well in the open if kept shaded.

I believe there are a good many other members of this precious genus, so valuable for the scree, yet to be introduced to our gardens; I could almost wish that some one would give the alpines of the high Himalayas and China the attention they deserve, and perhaps give the Primulas and Rhododendrons a little rest, although we still have some lovely Primulas to come, either as newcomers, or re-introductions, even although some of them are such miffy subjects, best left to those who are fortunate enough to have gardens in Scotland, where the climate seems so nearly like that of their own native habitat. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

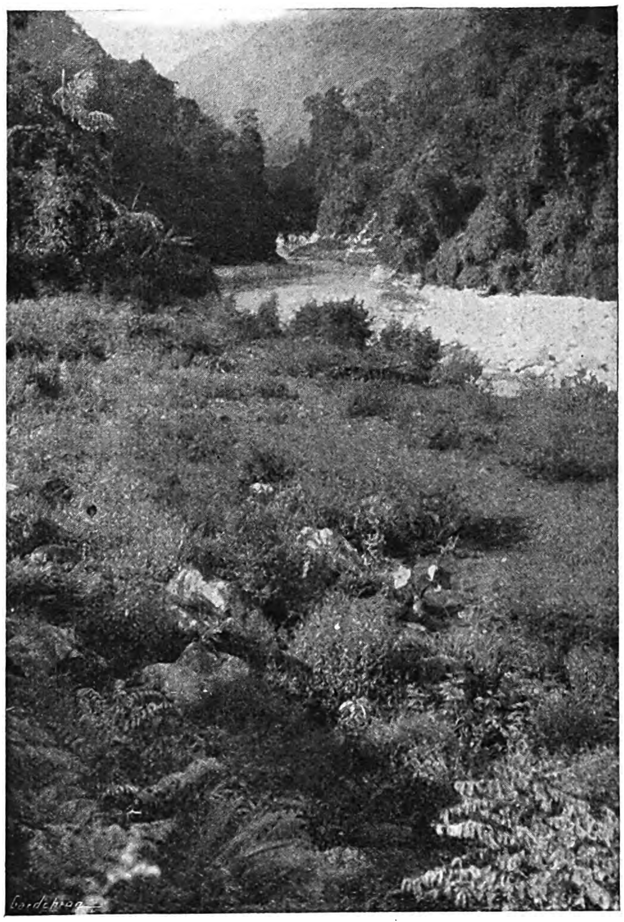

FIG. 139.—A HILL STREAM.

Mr. F. Kingdon Ward's Expedition.

FLOWER GARDEN.

ADLUMIA CIRRHOSA.

Not the least attractive effect this season has been a low fence clothed with this North American climber; of somewhat delicate appearance, the plant is a mass of slender, twining stems and small Maidenhair Fern-like leaves, and the purplish-rose flowers are produced freely on axillary peduncles, usually four-flowered; the leaves are triply-pinnate and of fresh pale green colour.

A biennial, this charming plant may be raised from seeds sown in spring in a shady position; it enjoys a warm, rich soil and in favoured districts perpetuates itself by self-sown seedlings, but it is, I think, seen at its best when grown in a cold greenhouse.

Sometimes known as Corydalis fungosa—the plant is, indeed, lucidly described as a climbing Fumitory. A. cirrhosa was introduced so long ago as 1788. *E. A.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXII.—The Riddle Solved.

SEPTEMBER was the foulest month of all, so far. It rained incessantly, and both Buttercup and I were laid up for several days. There was no point in attacking Polon until the weather improved, as we could not possibly see our way along the ridge; and besides, the steep faces were so slippery that we could scarcely get up them at all. The assault was put off day after day, and still the mist rolled up, and the rain came down in sheets. After the middle of the month I was busy collecting seeds of the forest Primulas. Several times I climbed to the first alpine top, and further along the ridge, but it was always to explore the high gullies, where I hoped to find the red Primula; and each time I was disappointed. However, on the 27th I decided to attack Polon again, whatever the weather, and Buttercup's foot being better, he announced his intention of coming too. Making an early start, we reached our previous furthest point in three-and-a-half hours. Now we divided our forces, and while I started to hack a path through the thick scrub, chiefly Bamboo and Rhododendron, which covered the ridge, Buttercup followed a faint trail which plunged steeply down the shoulder.

After half-an-hour, having made fair progress along the ridge, I came to a cliff, and things looked hopeless; there was not and never had been a path here, at any rate. So I shouted to Buttercup, and presently discovered that he was below and ahead of me, apparently moving parallel to the ridge; our voices, however, were strangely distorted by the mist or the mountains, now coming from one direction, now from another, so that it was some time before we connected. Finally I made my way down a boulder scree overgrown with tall herbs, and found Buttercup on a path which traversed the face below the cliff. He had followed the faint trail, which in spite of a most deceptive descent for five hundred feet, turned out to be the hunters' path after all; a little further on he had discovered quite a snug cave, whence the path climbed sharply up the face again; and the way to the alps was at last clear. We had no time to explore further that day, but we spent half-an-hour here before turning back, and I collected a few seeds of Primula prenantha, and some plants in flower, including a big purple Thistle, or Cnicus, and a Saxifrage. As already remarked, the boulder slope was covered waist deep with tall plants, Geranium, Astilbe, Panax, Polygonum, Strobilanthes, Rheum, and many others; but the face, as a whole, was still clothed with Bamboo and Abies and Rhododendron forest, chiefly the 'Falconeri,' 'Keysii' and 'Thomsoni' species of the latter, which herald the approach to alpine conditions.

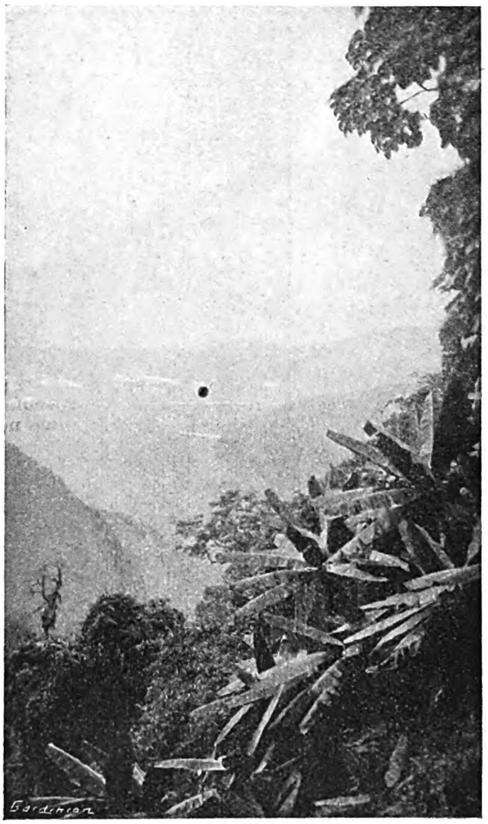

FIG. 140.—THE ASSAM VALLEY FROM THE FIRST TIER OF HILLS; LOHIT RIVER IN THE DISTANCE.

Returning along the ridge, I noticed that several shrubs had coloured well, including a small Viburnum (claret-red) and two Rhododendrons. Of the latter, R. tephropeplum had turned orange and flame-coloured, while the odious little yellow epiphytic monstrosity, about which I could find no good word to write, had turned stark scarlet, with vermilion fruits. There are not many Rhododendrons of my acquaintance whose claim to distinction is based on autumnal colours. A form of R. yunnanense collected at Muli some years ago, coloured well; and there are several species of the 'Roylei' and 'Souliei' types—'Orange Bill' and 'Yellow Peril' from Tibet spring to memory—whose young foliage has by autumn taken on a fine glaucous or verdigris-green. But these two plants, R. tephropeplum and the yellow epiphyte, would be worth growing for autumn effect alone—and R. tephropeplum is a good plant anyway. I remarked, however, that it was only at comparatively high altitudes—10,000 to 11,000 feet, and in exposed positions on the ridge, that the correct colour effect was produced. This applied especially to the epiphyte, which was common at 9,000 feet, in thickets, growing on boulders; and there it had not coloured at all, although the thin fruits reddened well.

Along the open ridge there grew a dwarf Ilex, with small, matt-green, Box-like leaves and tiny scarlet berries. It formed a semi-erect, massive undershrub, and would make an excellent dwarf bush for the rock garden. At lower altitudes, among the big-leafed Rhododendrons, it was replaced by a larger bush species with shiny leaves, which looked as though it would make a good hedge. These two, the dwarf Ilex Pernyi, a species rather like I. Aquifolium with unpolished leaves, a broad, leathery-leafed species which recalls I. dipyrena, and the queer I. nothofagacifolia, were the only species of Ilex met with in the high forest. Four species of Acer were collected, including A. pictum; but only one of them coloured in autumn.

At the end of September, I made a day's excursion to the gulley where the woodland Primulas grew, and collected more seeds of them, besides the Nummularia; and from the sunny side of the ridge I gathered seeds of the magenta Impatiens. By this time I had seeds of about twenty-five species, and the problem was how to dry them. There was no sunshine, our camp in the forest was always wringing wet, and nothing would dry in my tent. In the end, I was reluctantly compelled to dry them by the fire. Three days after our discovery of the route to Polon, on October 1, I determined to carry out the final exploration, and reach the alpine region. It was a terrible day, pouring with rain before dawn, and breakfast by candle light was a chill and dreary business. However, once away and thoroughly soaked, I made good progress up the now too familiar trail. The cave was reached in three-and-a-half hours, which was good going on such a day; here I dumped some tins of pemmican. The day was still young, and I started up the steep trail towards the ridge, full of confidence. In half-an-hour, I was in the sub-alpine region of scrub Rhododendron—'Sanguineum,' 'Roylei' and 'Coals-of-Fire.' There was a dwarf Rose here, too, and a Pyrus with bunches of snow-white berries. Now I was climbing up a steep rock scupper, which spouted water as the rain descended in sheets; and all along the edge the Gamboge Primula was in ripe fruit, hundreds of plants! I had to go slowly here, collecting seeds as I went, but always going steadily up. Now the trail turned across the face again, slanting towards the ridge, and the alpine plants increased in number. There was the tall, yellow Gentian in fruit—I did not see this at Kaso—and a small, blue Gentian in flower; but mostly the rocks were covered with thickets of crouching Rhododendron.

Suddenly I came out into the open, no more trees, no bushes even, just steep alpine meadow, with outcrops of rock, and escarpments beneath which clumps of Rhododendron huddled, and dwarf shrubs, Rose and Lonicera, pressed into crevices. On the first rock slope, I found the pallid, yellow 'Nivalis' Primula, and then, pushing up the slope through the dying meadow, at last the red 'Sikkimensis' Primula! So I went on up towards the ridge, in the stinging rain, collecting fruits of Rosa and Lonicera (which has fragrant white flowers like a Daphne, and fat, translucent, blood-red berries, dangling on long stalks), and of Primula. At last, I reached the very top of the ridge, and knew I was close to the peak of Polon; but I could see nothing in any direction, so thick was the cloud. It was chilly here, too, the altitude being nearly 13,000 feet. I noticed that the slopes were mostly covered with alpine flowers, an Aster, several Saxifrages, a pink Polygonum, and a few others being still in bloom. The leaves of a small Euphorbia formed bright scarlet patches; and among several plants in fruit were the red Nomocharis, Anemones, Caltha, dwarf Umbelliferae and Phlomis. But there were very few dwarf Rhododendrons, the commonest being the purple 'Saluenense'; over the ridge, too, were gnarled bushes of the beautiful species with wash-leather leaves and speckled pink or yellow flowers, suggesting Rhododendron lanatum.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; September 7, 14, and 28, 1929.

More seeds were collected during a tour of the face, and I spent some time hunting for the red Primula, which was rather widely scattered, and hard to see, being only about a foot high, with very slender capsules. About three o'clock I started for camp with a fine lot of stuff. There was a brief lull in the storm, and the clouds lifted sufficiently to reveal the ridge, but not the peak. However, it was soon raining again as hard as ever, and I reached camp soon after nightfall, the climb having taken eleven-and-a-half hours.

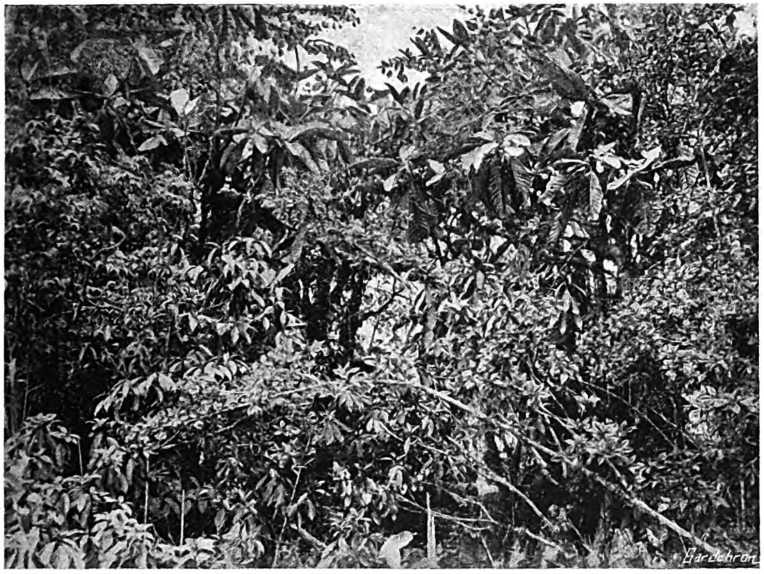

FIG. 141.—TANGLE OF FOREST.
9,000 to 10,000 feet altitude.

I have mentioned that I had dumped several tins of pemmican at the cave; also a tin of biscuits. This pemmican was Buttercup's idea, his experience in the Arctic having taught him its value; and in March he had written to England for some. It arrived with our last supply—40 lbs.—just in time to be of the greatest service. Indeed, it saved the situation. Already we had been obliged to knock off our Rice ration, as we found that there was barely enough to suffice Luso until the middle of October; and for the remainder of our time in the Mishmi hills we lived almost entirely on flour, chocolate, and pemmican, the latter making a very rich and sustaining soup. The advantage of this pemmican was its concentration, a pound tin, with a few biscuits and two slabs of chocolate being sufficient food for one man for four days. Thus it was exactly what was required for the Polon and Kaso climbs we had in prospect. Either of us could easily carry a week's food, a cooking pot, and a little extra warm clothing in a rucksack; if both of us went, we could do ourselves quite comfortably — although Buttercup's foot was bad again, and I realised that he would probably be unfit for the climb. Still, there was Hubble; he had behaved better since his return to the fold, and might be of some use.

In view of the assault on Polon, which was fixed too optimistically, for October 8, I thought it advisable to form a small food dump at the cave; hence, the pemmican. The only other incident of mark in September was the arrival of a mail, or rather the bye-product of one; for a Mithan had doubly distilled it en route during the night. *F. Kingdon Ward.*

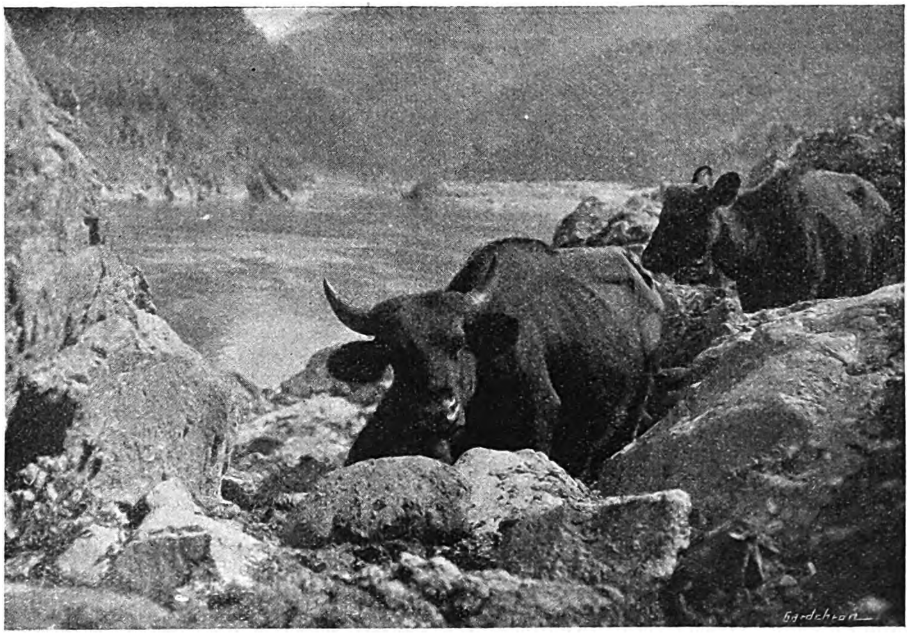

FIG. 142.—MITHAN: THE COW THAT ATE THE MAIL.

NOTICES OF BOOKS.

Fungi.*

THE above is one of the books of Benn's Sixpenny Library, which deals with all sorts of subjects, the present being No. 68. The author, apparently, considers that Fungi are neither plants nor animals, but are related to the former by the fact that they obtain their food in solution by osmosis through a membrane, and reproduce themselves by spores in the case of the higher fungi, just like vascular cryptogams. On the other hand, they have no chlorophyll, cannot build up their own carbohydrates by photosynthesis, and in this respect resemble animals. This would postulate that plants possessing chlorophyll must have existed prior to animals or fungi. After discussing the views that have been held about the origin of fungi, the author states that an opinion becoming more generally accepted is that fungi were originally derived from colourless flagellates, related to the green ones which gave rise to algae. This would imply a very ancient origin, but the geology of the rocks does not help us much owing to the perishable nature of the fungi.

The whole subject is dealt with in seven chapters, which are packed with interesting facts, including chapters on structure, fungi and man, plant pathology, symbiosis, fungi and insects. The dormant bodies, known as sclerotia, which enable fungi to tide over the winter or any other conditions unfavourable to growth, vary in size from that of a small seed to that of a boy's football. Many large sclerotia are eaten by natives. The dry-rot fungus is mostly confined to worked wood in buildings. Some idea of the enormous wastage of spores may be gathered from the fact that the giant puff-ball (Lycoperdon Bovista) is computed to produce seven million millions of spores, which would soon cover the globe, if all were effective. One spore, however, can produce a fairy ring, and that is effective during the life of the ring, whether that is a few years or centuries. In the chapter on fungi and man, it is stated that the poisonous fungi probably do not exceed five per cent. of all toadstools.

The making of wine from Grapes, cider from Apples, and perry from Pears is due to fermentation, caused by minute fungi, known as yeasts, which are of many species. By the ancients, these alcoholic beverages were made by exposing fruit juices to the air, but the modern brewer and baker depend upon pure cultivated strains. Yeasts of different species are known to inhabit the bodies of insects, and are not known to have an independent existence. Parasitic insects extract juices from plants and the juices are fermented by yeasts. In the discussion of mycorrhiza or fungi on the roots of plants, it is interesting to note that a species of Phoma penetrates the roots and ascends the stem, leaf and fruit capsule of Calluna vulgaris, so that the seed coat probably gets infected from that source and the seed is enabled to grow. Fungi share with bacteria the breaking down of all organic matter in the soil, making it fertile for the higher vegetation.

The book runs to eighty pages, including two of enlarged illustrations of parts of fungi, which should be of considerable assistance to beginners in the study of the subject. A careful study of this introduction should induce the reader to go further in some branch of mycology.

---

* *Fungi, an Introduction to Mycology*, by J. Ramsbottom, O.B.E., M.A., British Museum (Natural History). London: Ernest Benn, Ltd., Bonverie House, Fleet Street, E.C.

Agricultural Entomology.*

It would be a mistake, by judging from the title of this book, to imagine that it deals only with agricultural entomology; for it applies to field and gardens, large or small, and to domestic animals in considerable variety. Part I deals with the structure and classification of insects, which should interest the entomologist, as well as those who desire to glean an acquaintance with the insects that infest their crops; while Part II is termed the economic section, and runs from page 45 to page 314, including a good index. This latter deals with injurious insects, their prevention or remedies, and, incidentally, would interest the naturalist, in the life histories of insects, their metamorphoses, and migrations in order to complete their life-cycle.

The Collembola or springtails are small, degenerate insects that one would not readily suspect to be injurious to plants, yet some of them are accused of attacking Mangels, Sugar Beet, Currants and Apples. One hundred species of thrips are known in the British Isles, and Onion thrips are peculiar in having a bladder on each foot, which it is capable of inflating at will. The best-known thrips are those of Pears, Onions, Peas, Beans and Grasses, and some of them are stated to fertilise the flowers of Beet. The Pea and Bean thrips (Frankinella robusta) burrows several inches into the soil to pass the winter, yet it was formerly recommended to burn the Pea sticks. It is highly destructive, and stated to be impossible of eradication by spraying, yet gardeners think they can destroy it by repeated spraying with soft soap, if taken in good time. The above is the third scientific name that has been given it to our knowledge.

Rhynchota is here given as a general name for plant bugs, capsids and aphides, instead of Hemiptera, because they all agree in having a long proboscis or mouth parts for extracting the juices of plants, whereas the structure of the wings varies considerably in this large group or class of insects. It is here calculated that the uninterrupted breeding of ten generations of aphides would equal the bulk of the population of the Chinese Empire. Happily, their special foods would fail them long before this could happen, independently of many other natural checks. Aphides are suspected of spreading the virus diseases of Potatos. The leaf-curling Plum aphis is highly destructive, yet hundreds of the gardening fraternity never notice it until long after the damage is beyond remedy, while even market growers suffer it passively, many of the public generally attributing it to some mysterious effect of the weather. Among other remedies, preparations of vegetable poisons, such as Derris root (Leguminosae) are effective against this aphid. The woolly aphis has been found feeding on the Apple, Elm, Hawthorn, and a similar or identical one on the Pear. It lays one winter egg on the Elm. Aphis rumicis, such a scourge to Broad Beans, Runner and Dwarf Beans, feeds on a great number of plants, migrating from one to the other. It reaches maturity in a week or so, and five generations are calculated to number a hundred millions, if unchecked. No details are given of the mealy Cabbage aphis, yet acres of Cabbages and other Brassicae are being rendered useless by it at the present time in the east of England; and the pest ruins the plants being grown for seeds in Essex occasionally.

Capsid bugs, white fly, scale insects, caterpillars, ants, bees, sawflies, craneflies, true flies, red spider, eelworms, millipedes, snails and slugs are all passed under review and remedies given in some detail. A chapter is devoted to insecticides, with their composition and application.

The book is amply illustrated throughout with line drawings and reproductions of photographs. Altogether, it is highly informative and should be on the shelves of every cultivator. Paper, printing and editing are excellent.

PROBLEMS OF PLANT LIFE.*

XI.—The Significance of Bloom.

Our problem now is to discover the part played by bloom in the economy of plant life. In the early days of spring, with the first appearance of the Celandine's gold-enamelled blossoms, it greets us, and remains with us in ever-varying form throughout the remainder of the year.

We are taking the word "bloom" in its widest sense. It embraces not merely the enamel of the Buttercups or the waxy film of the Grape, but all those forms which, whether they occur on stem or leaf, blossom or fruit, tend to throw light on our subject. Fully to understand the matter we must include the delicate pile of the Sugar Cane knot or node, the velvet of Peach and Apricot, and the hairs of the Gooseberry and Bogbean, as well as the gloss on evergreens, and the glaucous coating of a Cabbage leaf. It may be found on almost every part of the plant above ground, and is not limited to fruit or flower, whether wild or cultivated, but occurs in connection with plants of the desert and the seashore as well as the wildings of our fields and hedgerows and the choicest products of the East. We use the word figuratively as a synonym for what is youthful, healthful and beautiful; and when bloom is seen, whether on the face of a damsel, the coat of a horse, or the cheek of a Plum, it gives pleasure and delight.

As varied as are the forms it assumes and the parts it adorns, so varied are the ends which it serves. The old teleologists, seeing it on the ripened fruit, would have said it was designed to give it beauty. If we can hardly go so far to-day, it is not unreasonable to suppose that it serves the same end as colour in relation to birds, and gives them timely notice when the fruits upon which they feed are ready for their services as seed-distributors. In the case of wild fruits, such as Sloes, for example, it would be to the advantage alike of the bird and the plant that there should be some indication when the fruit was at its best. In this way we may still find some justification for the old doctrine of design. It is not altogether out of harmony with what the newer theories of evolution have taught us.

It will be seen that when we speak of bloom we are not using it in the sense of blossom, although both ideas are ultimately traceable to the same stock. The word blossom or bloom has branched out in two directions, and so has come to mean both the flower itself, and that delicate something which beautifies the various parts of the plant, although it is not an organ, and serves a variety of ends. Although it has for ages been observed that bloom occurs, the problem of its significance is a modern one. This we gather from a study of its history; and we have only to turn to the writings of Charles Darwin—that tireless investigator of every problem relating to plant life, to see how little was known about bloom before his day. If we take, for example, such a well-known work as Robert Brown's *Manual of Botany*, published in 1874, we shall look in vain for any guidance in the matter of bloom. No reference is made to it when the various fruits are described, and when the leaves are discussed the following sentences are the only ones which bear upon the subject.

"*Leaf-excretions.*—Of this nature we are inclined to regard the resinous substance seen on the buds of many plants, the sugary substances which cover the Sycamore leaves in the course of summer [Qy. Honey-dew ?], the fragrant resinous substance covering the leaves of the Cinnamon Laurel (*Ceanothus velutinus*) of North America, . . . the wax of the leaves and stems of the Candleberry Myrtle (*Myrica cerifera*), and the layer of wax which covers the Wax Palm (Ceroxylon andicola). Of a similar nature are probably the excretions given off by the hair-like structures of the leaves of Drosera."

Clearly, we have advanced a good deal in our knowledge since this paragraph was penned. Three years earlier Balfour's *Class Book of Botany* had appeared, and here again, while bloom is almost unknown, wax is spoken of as follows:—

"Wax is found in the tissues of plants, and it frequently occurs as a secretion on the stems, as in the Wax Palm, and on the surface of fruits, as in the bloom or glaucous secretion of the Plum and the Candleberry Myrtle. Wax (he adds in a footnote, p. 36) forms a layer on the fruit of Croton sebiferum, Lornia sebifera, Rhus succedaneum, leaves of Enkephalortos, bracts of Musa paradisaica and Strelitzia formosa, and stem of Ceroxylon andicola. Chinese vegetable tallow is procured from the seeds of Stillingia sebifera, and Shea or Galam butter from a species of Bassia." But neither Brown nor Balfour attempted to solve the problem which we have in view.

It was just when these volumes were being placed in the hands of students of plant life that Darwin "sought some explanation of the waxy coat or 'bloom' and layer of fine hairs upon leaves and fruits" from Sir J. D. Hooker, at that time Director of Kew Gardens, and from the letters which passed between them, and the notes of their biographers, some of the following facts have been gleaned. To men of Darwin's type of mind the mere accumulation of facts and phenomena means nothing. The vital question is— What do these things mean ? His researches into the meaning of the bloom or waxy coating found on fruits and leaves, although left unfinished, resulted in the amassing of a large quantity of notes. Some of these, concerning the relation between bloom and the distribution of stomata, appeared in 1886 in the *Journal* of the Linnean Society. He sought help in every direction, and his correspondents included Dr. Asa Gray, Sir Thomas Farrer and Sir W. Thiseleton Dyer.

One of the first and most obvious explanations was that bloom on leaves, flowers and fruits kept water from settling on them and so proving injurious. Injury might result in various ways. There was the question whether drops of water acted as burning glasses. He pressed this question on all his friends, but in 1877, while stating that he believed that bloom prevents injury from pure water resting on the leaves, this is as yet "the most doubtful and the most interesting point in relation to the movements of plants."

Then came the question of transpiration. In 1850, Garreau had noted that bloom is a check on the action of leaves. Darwin worked independently on the subject, and both he and Tschirsch published identical results with those of their predecessors. But while this was true of leaves, what of fruits ? Here, too, it has been found that bloom serves a great end. Let me quote from the Rev. Hugh Macmillan:—

> "You have all, I am sure, got some time or other, a newly gathered bunch of Grapes from a hothouse. You have noticed what a beautiful bloom there was on each berry, and how it set off the rich glowing purple hue of the Grapes by the contrast of its grey colour. You have touched this bloom very lightly and it vanished. Had that berry been growing on the vine when you touched it and thus rubbed off the bloom, which serves an important purpose in the economy of the fruit, regulating its temperature, the berry would not be able to resist the forces opposed to its welfare, and it would soon decay, and in the place of the beautiful bloom would come the grey unsightly mould of a destructive fungus."

Thus the bloom not only checks transpiration and regulates the heat, but acts as a shield against invasion by microbes, yeasts, ferments, bacteria and other insidious aggressors. One writer informs us that the bloom of the Grape is due to a thin, waxy coat which, unfortunately, is not sufficient always to protect the berries from fungi. It is a question, however, whether the spores of fungi could ever germinate on the bloom while it remains perfectly intact. I have just examined a specimen and find that the bloom resembles a thin, even wash of grey water-colour which may readily be smudged away. The Grape was covered with microscopic matter, invisible to the naked eye, but one could find no sign of germination. If, however, germs are brought into contact with an abrasion or wound, they soon begin to grow. The bloom of the Grape, Plum, Sloe and other fruits seems to be the most delicate form of secretion or protection. In the Peach and some other fruits it takes the form of a pile or coat of velvet; then we pass to such forms as the Gooseberry, where we find the hairs greatly elongated, and the more delicate bloom wanting. In such fruits as the Apple we have something approaching a layer of cork, while crystals of different kinds are found in other fruits and leaves, suggesting that insect and other foes have to be met and checked. *Hilderic Friend.*

THE GENUS PRIMULA.

(*Continued from p.* 250.)

ROYLEI (Balf. f.). Royle's P.
(Petiolaris-Roylei).

A VERY beautiful, perennial species from the Himalayas, with a stout rootstock which produces numerous, erect, oval-pointed scales one-and-a-half inch to three inches long, coated with yellow meal; these scales surround the flower stem at flowering time. The congested rosettes of leathery leaves have oblong, blunt blades contracted into strap-shaped, broadly-winged stalks dilated and clasping at the base, in all from three to five inches long; margins furnished with sharp, irregular teeth as though gnawed by insects; both surfaces clothed with minute, capitate, meal-producing hairs. Flower stem four to seven inches tall, more or less mealy and bearing an umbel of about two dozen purple, violet or pink blossoms with a deep purple or nearly black eye surrounding the yellow mouth of the tube; a cream-coloured form has also been recorded. Corolla about one inch across, slightly concave, with spreading and overlapping, oblong or egg-shaped lobes, retuse at the tips; tube funnel-shaped, slightly longer than the calyx, with a ten-lobed ring in the mouth. Flowers from May to August.

Grows in alpine pastures, at times in shade, near Jongri, Sandakphu, Tari and Megu, in the Sikkim Himalayas, at from 11,500 to 14,000 feet above sea-level., also near Kanglanamo, in the Nepal Himalayas, and in south-eastern Tibet, at 15,000 feet above sea-level.

Var. acaulescens (Balf. f.). A stemless form with elongated flower stalks about four-and-a-half inches long, and longer leaves. Sandakphu, Sikkim Himalayas, at 10,000 to 12,000 feet. Flowers in May and June.

The type has been in culture since 1887 under the name of P. obtusifolia (Royle) and P. obtusifolia var. Roylei (Hook. f.). The type is illustrated in the *Bot. Mag.*, t. 6,956 under P. obtusifolia.

Culture: As for P. petiolaris.

RUFA (Balf. f.). Rusty P.
(Bullatae).

A robust, sub-shrubby evergreen species more or less covered, with the exception of the corolla, with minute, rust-coloured hairs. The woody, branching, rootstock is clothed with the dried remains of the previous seasons' foliage, and the fragrant leaves are produced in dense tufts and have elliptic, blunt blades from one-and-a-half inch to two-and-a-half inches long, gradually tapering to a winged stalk, dilated at the base, about one inch long; margins edged with broad, rounded, regular teeth; upper surface slightly bullate, underside covered with golden meal. Flower-stem erect, six to nine inches tall, non-mealy, bearing a many-flowered umbel of golden-yellow blossoms with their tubes more or less covered with yellow meal. Corolla about five-eighths-of-an-inch across, with rounded, bifid lobes; tube about half-an-inch long, nearly twice as long as the calyx. (Illust. in *Trans. Bot. Soc. Edinburgh.*, Vol. XXVI, 1913.)

Grows in the clefts of rock and on the ledges of cliffs, on the mountains near Heechanmen, in Yunnan, western China.

Culture: As for P. bullata.

RUPESTRIS (Balf. f.). Sticky Chinese P.
(Sinensis).

A rather small-flowered, perennial species with the whole of its foliage, stems, calyces and blossoms covered with long or short, viscid, glandular hairs. The tufts of dark green leaves have elliptic-oval or almost circular blades from three-quarters- to one-and-a-half inch long, rounded at the tip, heart-shaped at the base, borne on a rounded stalk from two to three-and-a-half inches in length, slightly expanded at the base; margins usually divided into seven unequal, rounded or truncate lobes ending in a red tooth; underside prominently veined, more or less red. Flower stem from four to six inches tall, bearing one or two superposed umbels of about half-a-dozen white, lilac or rose-coloured blossoms with a greenish-yellow eye; the slender, reddish stalks are from three-quarters- to one-and-a-half inch long. Corolla flat, three-eighths- to half-an-inch across, with rounded, heart-shaped, deeply-notched lobes; tube cylindrical below, dilated upwards, about twice as long as the calyx. In cultivation in 1916.

Grows in clefts in dry limestone cliffs in the Ta-Pa-Shan, in Szechuan, western China, at elevations up to 8,000 feet above sea-level.

Culture: As for the typical P. obconica.

RUPICOLA (Balf. f.). Boulder P.
(Souliei).

This rather dwarf, perennial species produces numerous tufts of thin foliage from the same rootstock, which is clothed with the dried remains of that of previous seasons. The leaves have oblong-lance-shaped or narrowly egg-shaped blades about one inch to two inches long, gradually tapering to a winged stalk two to four inches long; margins somewhat sinuate, coarsely and irregularly toothed or bi-dentate, edges fringed with fine hairs; both surfaces moderately downy; underside, when mature, sparsely coated with yellow meal, densely so when young. Flower stem three to seven inches tall, more or less downy or mealy, bearing an umbel of about eight deep purplish-blue or rose-coloured blossoms with a yellow eye, on erect stalks. Corolla about three-quarters-of-an-inch across; segments spreading, egg-shaped or broadly heart-shaped, bifid at the tip; tube cylindrical, dilated upwards, with a ring in the throat, white, veined purple, larger than the calyx. Flowers in June and July. In cultivation in 1922.

Grows on boulders and in open, stony pastures on the mountains of the Yangtze bend, in Yunnan, at 12,000 feet above sea-level; also on the shady ledges of limestone cliffs and among scrub, near Muli, in south-western Szechuan, at 13,000 feet above sea-level.

Culture: Gritty loam and peat mixed with limestone chips in an open or half-shady situation, with protection from damp in winter, should suit it.

RUSBYI (Greene). Rusby's P.
(Nivales).

A beautiful, slender perennial species of tufted habit with broadly lance-shaped, rather blunt, membranous leaves three to five inches long, tapering to a narrowly-winged stalk about equalling the blade in length; margins finely or coarsely toothed; both surfaces smooth, non-mealy. Flower stem slender, four to nine inches tall, mealy among the flowers, bearing an umbel of six to ten nodding blossoms of a bright rose-red or crimson-purple colour with a darker ring at the base and a yellow throat. Corolla about three-quarters-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, slender, more than twice as long as the calyx. Introduced in 1881. *Bot. Mag.*, t. 7,032.

Grows in the damp ledges of cliffs usually facing north, on Mount Mongollen, in New Mexico, and Mount Santa Rita, in Arizona, U.S.A.

Culture: Plant it in fibrous loam, peat, leaf-soil and sand, in a cool, damp spot in the rock garden, with protection from damp and severe frost in winter.

RUSSEOLA (Balf. f.). Russet-leaved P.
(Nivales).

An extremely robust and very handsome species with stout, mealy resting buds and tufts of elongate leaves with oblong-oval, blunt or sub-rotund blades, tapering to a long, membranously-winged stalk, in all from nine to twelve inches long; margins furnished with minute teeth; upper surface pale green when young, turning russet colour when mature, underside finely coated with white meal. Flower stem stout, nine to fifteen inches tall, slightly mealy, bearing a many-flowered umbel of fragrant, deep navy-blue or rich purple-rose, grey-eyed blossoms on stalks about one inch long, coated with white meal. Calyx brownish-purple. Flowers from June to August. In cultivation in 1925.

Grows in moist, stony pastures and in crevices of damp, cool cliffs in shady valleys, on the mountains around Muli, in south-western Szechuan, at 11,000 to 12,000 feet above sea-level; also at Kagwrpu, near Tsarong, in south-eastern Tibet.

Culture: As for P. nivalis.

SAPPHIRINA (Hook. f.). Sapphire P.
(Soldanelloideae).

A very beautiful little species of densely tufted habit, with rosettes a quarter- to half-of-an-inch across, of minute, egg-shaped, spathulate or wedge-shaped-spathulate, blunt leaves narrowed to short stalks; margins pinnatifidly toothed; both surfaces covered with white, scattered hairs. Flower stem one inch to two inches tall, very slender, bearing one to four stemless, nodding flowers of a bright or pale sapphire-blue colour. Corolla funnel-shaped, about a quarter-of-an-inch across, with oval, notched lobes; tube short, broadly funnel-shaped, very little longer than the calyx. Flowers in May. Introduced in 1887; soon lost. *Bot. Mag.*, t. 6,961.

Grows in rocky alpine pastures, flowering on the edge of melting snow, in the Sikkim Himalayas, at 12,000 to 16,000 feet above sea-level.

Culture: Grow it in gritty loam and peat, in a damp, cool spot, with protection from damp in winter, or treat it as a cold frame plant.

SATANIENSIS (Balf. f.). Satanee P.
(Cortusoides).

This rather handsome perennial plant is a sub-species of P. polyneura (Franch.); it produces a tuft of thin leaves with heart-shaped blades about three inches long, borne on distinct hairy stalks about five inches in length; margins very deeply cut into ten or twelve blunt, obscurely toothed lobes; both surfaces sparsely clothed with glandular down. Flower stem nine to fourteen inches tall, bearing an umbel of about half-a-dozen almost stalkless, purple-rose blossoms with a tube that is longer than the calyx.

This species is found in shady places on the Satanee and Gahoba Ranges, in Tibet.

Culture: Good, friable loam and Oak or Beech leaf-soil, in a cool, moderately damp, shady spot, are the conditions suggested.

SAXICOLA (Craib). Himalayan Rock P.
(Petiolaris-Sonchifolia).

A dwarf, tufted, deciduous perennial species with a rosette or tuft of membranous, green, usually smooth leaves with blades varying from oval to spathulate or spathulate-elliptic, wedge-shaped, heart-shaped or truncate at the base, tapering to a more or less winged stalk, in all from two-and-a-half to four-and-a-half inches long; margins lobulate, lobes edged with sharp teeth. Flower stem not developed; flower stalks one to two inches long, slender, downy with glandular hairs, each bearing a solitary blossom the colour of which has not been recorded, but is in all probability purple. Corolla about one inch across, with egg-shaped or egg-shaped-wedge-shaped, trilobed segments; tube about three-quarters-of-an-inch long. Not in cultivation.

This species is found at Kulu and in the Châchpur Valley, in the north-western Himalayas, at about 5,000 feet above sea-level.

Culture: Good, rich, fibrous loam mixed with Oak or Beech leaf-soil and a cool, damp situation in the rock garden should suit this species.

SCAPIGERA (Craib). Tonglu P.
(Petiolaris-Sonchifolia.)

This deciduous, perennial species, which was formerly considered to be a form of P. petiolaris, has a short, thick rootstock, which produces a tuft of membranous or Papyrus-like, smooth leaves with oblong-spathulate, oval, oblong-elliptic or oblong blades, widely wedge-shaped, truncate or heart-shaped at the base, contracted into a short, broadly or narrowly winged stalk, in all from three to six inches long; margins somewhat thickened, edged with irregular teeth. Flower stem almost obsolete or equalling the foliage in length, frequently much surpassing the leaves when in fruit, very stout and bearing a few- or many-flowered umbel of large blossoms, on stout stalks one to two inches long; the colour of the blossoms is usually some shade of purple. Corolla over one inch across, with bilobed or trilobed, irregularly-toothed segments; tube cylindrical, about three-quarters-of-an-inch long.. In cultivation in 1920.

This is apparently a common species near Tonglu, in the west Sikkim Himalayas, at 7,000 to 10,000 feet above sea-level.

Culture: As for P. saxicola. *A. W. Darnell.*

(*To be continued.*)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)
(*Continued from p.* 270.)

ENGLAND, S.W.

Gloucestershire.—I have heard no good reports on the Apple crop in this district. Most of the trees blossomed very well but failed to set fruits; a few trees, however, have a fair crop. Pears are very good; the fruits have been severely thinned, and the trees look well. We had heavy crops of bush fruits, but Strawberries were very poor, which is unusual here. The soil, is friable, overlying old red sandstone. The rainfall here for the six months ending June 30 was only 7·23 inches. *John Banting, Tortworth Gardens, Falfield.*

—— The Apple crops are somewhat below the average. Bramley's Seedling suffered through the buds being frozen before they opened; other varieties flowered well, but many fruits fell after setting. Pears, on the whole, are a fair crop. Plums are patchy; in some places the trees are cropping heavily, especially Purple Pershore, Victoria and Czar, but in others the crop is light. The Blaisdon Red, which is largely grown in the Severn Vale, is rather over half an average crop. Crops of Gooseberries constituted a record, both for weight and quality. Black Currants and Raspberries were good, where they were not injured by frost. The first Strawberry blooms were killed by frost, and the crop, as a whole, cannot be called satisfactory. *G. H. Hollingworth, Shire Hall, Gloucester.*

Herefordshire.—There was a good average crop of all bush fruits in this district, but owing to the drought, Strawberries were small and the season for them short. Apples are patchy, some trees having heavy crops, others very light indeed; Warner's King has the heaviest crop, while Cox's Orange Pippin trees are practically barren. Peaches and Nectarines carried heavy crops, the fruits being of first quality. Pears vary a good deal, and on the whole are a light crop, while Plums also are variable. The soil in this garden and district consists of heavy clay. *J. B. Cooke, Ledbury Park Gardens, Ledbury.*

Shropshire.—The crops of hardy fruits are far from satisfactory, especially so in the cases of the more important kinds, particularly Plums, which are a complete failure, although there was abundance of blossom. Morello Cherries were the most prolific of stone fruits. Apricots are clean and healthy and vigorous, and it is not easy to explain why the blossom failed to set. We are favoured here with a heavy loam soil on a subsoil of clay. No fruit trees suffered from drought, except Cherries. *Roger F. Jones, Oteley Hall Gardens, Ellesmere.*

—— Owing to the dry season, Strawberries were a very light crop. Black Currants, Red Currants, Gooseberries and Raspberries all carried good crops, also Peaches, Apricots and Figs out-of-doors, but Apples are below the average; such varieties as Newton Wonder, James Grieve, New Northern Greening and Worcester Pearmain had good crops, but many other varieties have no fruits at all. Pears, Plums and Damsons also are below the average, although the fruits are of good quality. *J. Clark, Sansaw Gardens, Clive, Shrewsbury.*

Worcestershire.—The Apple crop generally in this district is a very poor one, after a good show of blossom which, however, did not set well, owing, I think, to the very severe, dry winter and lack of rain in the spring. Caterpillars have been very destructive in most of the older orchards that were not sprayed, and some of the trees are nearly devoid of foliage, and the fruits punctured where there are any. Pears are a very good crop here. Plums are a fair average crop, also Damsons. Peaches, Nectarines and Apricots have carried good crops outside. Black Currants, Gooseberries and Red Currants, and Raspberries produced abundant crops of good quality. Cherries were very good. Strawberries were poor owing to disease, and Nuts are very scarce. Our soil is very light, overlying gravel. *H. T. Cheeseman, Strensham Court Gardens, nr. Worcester.*

—— The Apple crops are variable, being very good at fairly high elevations but nearly a failure in low, damp situations, subject to frosts at night; Pears and Plums are similar to the above. Cherries bore fairly good crops but the fruits were small owing to continued low temperatures and frosts at night. Peaches, Nectarines and Apricots were average crops. Small fruits were up to average, but rather late, Strawberries suffered considerably owing to the continued low temperature and cold winds, the fruits being of inferior quality. *William Crump, V.M.H., Oakridge, Richmond Road, Malvern Link.*

(*To be continued.*)

THE EDITORS' TABLE.

THE EARLHAM MONTBRETIAS.

We recently received from Messrs. Barr and Sons some grand sprays of several varieties of the Montbretias raised by the late Mr. Sydney Morris, of Earlham Hall, Norwich, and which both in size of flower and colouring, are vast improvements on the old type of Montbretia. They are very attractive when used for table decoration. Messrs. Barr and Sons have made a speciality of the Earlham Montbretias, as evidenced by the several bright displays of these set up by this firm at the recent fortnightly meetings of the R.H.S.

The varieties they sent us included His Majesty, probably the best, with huge, dark velvety-scarlet, gold-shaded blooms, dark crimson on the reverse; Fiery Cross, glowing fiery-orange, with a large primrose-coloured eye, stated to be a vigorous grower; Kathleen, with large blooms of good substance, broad, apricot-scarlet petals and a primrose-yellow eye, with small, maroon blotches; Red Knight, with large, star-shaped flowers of rich red shaded gold, and dull crimson on the reverse, and Queen Alexandra, rich yellow, flushed apricot, with blotches of crimson at the base of the petals. Several of these Montbretias have received Awards of Merit from the R.H.S., while the variety His Majesty has been honoured with the R.H.S. First Class Certificate.

AMARYLLIS BELLADONNA VAR. ROSEA MAXIMA.

Messrs. Barr and Sons very kindly forwarded to us a grand inflorescence of the lovely Amaryllis Belladonna var. rosea maxima, which was cut from a bulb which had not been planted and which flowered in their warehouse, without the aid of soil or watering. The colour of the blooms, of which there were seven, with three unopen buds, was not so intense as in blooms developed on plants out-of-doors, but they demonstrated well the remarkable vitality of this Amaryllis.

A. B. var. rosea maxima is much more robust and of richer colouring than the type, and is extremely fragrant.

HOME CORRESPONDENCE.

National Carnation and Picotee Society.—I am sorry if my original communication has roused the ire of the Hon. Treasurer of the Northern Carnation Society, but I have not the time, intention or desire to enter into correspondence on the subject. The down-to-date *facts,* which I am more concerned with than out-of-date history, were given in my letter and these are amply confirmed by the records of the National Carnation and Picotee Society in my possession, also by details given in the various horticultural directories. If further confirmation is needed, and I doubt whether it is, I would emphasise the fact that the Northern Carnation Society is affiliated to the N.C.P.S., that it pays the ordinary annual fee for this purpose, and is entered in our records under the title of Northern Carnation Society. Such an affiliation would be unnecessary if it was part of the N.C.P.S. I would remind Mr. Hewitt that there has been no break in the continuity of this Society's activities during recent times, whilst his own became defunct years since, and the present organisation (Northern Carnation Society) was only started in recent times. Mr. Hewitt has evidently had no experience in the organisation of a National flower society, if he thinks such a body cannot offer more advantages than an ordinary affiliated society, and I would point out that the N.C.P.S. has held exhibitions in the provinces and will do so again in a similar manner to other National flower societies. For Mr. Hewitt's information, the N.C.P.S. (not section, although for economy's sake we are still utilising some of the old stationery) is not out for cheap publicity. *A. E. Amos, Hon. Secretary, N.C.P.S.*

FOREIGN CORRESPONDENCE.

HUNNEMANNIA FUMARIAEFOLIA.

Hunnemannia is a monotypic genus named in honour of John Hunnemann, an English botanist who died in 1839. The only representative of the genus—H. fumariaefolia—is a native of the xerophytic regions of Mexico. It is known by the name of Mexican Tulip Poppy, and is one of the most satisfactory flower garden annuals available for use in the eastern United States. I have referred to this plant as an annual because it is always grown as such—at least in regions where winters are at all severe—although in its native country and in such favourable climates as that of California, it persists for several years.

To obtain good results, the seeds should be sown early, for the plants are extremely slow-growing in the young stages. Seedlings may be raised in pans and transplanted later, or a better plan, perhaps, is to sow three or four seeds in a small pot and thin out the resulting seedlings, leaving only the strongest, for, like most members of Papaveraceae, the Tulip Poppy resents disturbance at the roots. Grow them on in full sunlight, gradually harden off, and after all danger of frost is past, plant them in the open ground, allowing the same distance between the plants as would be considered satisfactory for Antirrhinums. Once the plants are established in their permanent positions growth is rapid; they revel in hot, sunny weather and rather dry conditions.

The plants are bushy in habit, from two to three feet high, and possess beautiful, feathery, glaucous-blue foliage. They are very floriferous, plants from early sowings commencing to bloom in late June and continuing right on until hard frosts cut them down. This is a valuable characteristic in this portion of the world, where so many of the familiar half-hardy annuals cease to flower either temporarily or permanently during the hot weather we are accustomed to expect during August.

The flowers of this subject are of the clearest possible lemon-yellow, resembling in general appearance (as does the whole plant) a large Eschscholzia, but having more substance. They are produced on erect stems, and each is two or three inches in diameter. During bright weather they are expanded, but in dull periods and in the evening they are partially closed, when they appear very much like a yellow, early-flowering single Tulip.

In addition to its value as a flower garden subject, the Tulip Poppy is excellent as a cut flower, and may be used with good effect in decorative work. Unlike the majority of Papaveraceous subjects, it stands well when cut, and will last in good condition for several days in water. An extraordinary amount of cut bloom is obtainable from a bed of Hunnemannia. The colour blends delightfully with the rosy-purple of Verbena venosa. Hunnemannia is also grown to a considerable extent in beds in greenhouses to help to supply the ever increasing demand for cut flowers. *T. H. Everett, Pleasantville, N. Y.*

STRAWBERRIES AND STRAW.

J. W. Morton, in your issue of June 15 states it is essential that Strawberries be marketed clean, otherwise they are worthless Personally, I quite agree with him, but here in the U.S.A. growers of Strawberries never seem to consider the matter of strawing down the plants, despite the fact that violent storms are apt to be frequent during the fruiting period. I have not seen a commercial field strawed down, nor have I ever bought berries that were free from grit. As a rule, it is necessary to wash the berries!

The general custom of Strawberry-growing here, even in gardens, is to allow the plants to become a dense mat; as a result one never sees really large berries, and seldom have they any real flavour; indeed, some berries sold more resemble mealy Potatos. Due to the wide area from which the fruits come, we, in the east, are able to buy Strawberries from February until July, the early crops coming from Florida. All the fruits are packed in smart punnets, these being shipped in crates holding about one hundred, in refrigerated cars. The earliest fruits generally make about 35 cents. a punnet, and the cheapest, about 15 cents. It is rare that one can buy a basket of fruits of even size, unless the salesman, usually the grocer in the smaller towns, picks them over himself and grades them. This is almost always necessary, as a matter of fact, if the berries are grown in some distant state, for such fruits are apt to be several days old and some mushy or mouldy specimens have to be removed.

Some years ago, I tried out a dozen varieties, but did not find one to suit my taste, and since the birds took heavy toll, no netting being available, I hoed out the lot. This season I am trying a batch raised from English seeds, but it is yet too early to state how they will turn out. The few that have fruited were only of moderate size, but the plants are healthy and have made runners freely. I do not, however, intend to adopt the matted system of culture, and hope next season to prove or disprove the statement that English Strawberries are of no service here. *T. A. W., New Jersey.*

SOCIETIES.

ROYAL HORTICULTURAL.

SECOND AUTUMN SHOW.

(*Concluded from p.* 274.)

Trees and Shrubs.

The Viscountess St. Cyres (gr. Mr. Honess), Walhampton Park, Lymington, Hants., sent an interesting collection of some of the less common shrubs. There were fruiting sprays of Umbellularia californica, Pittosporum Ralphii and Actinidia chinensis, while long trails of Araujia sericifera bore both flowers and fruits. Tecoma grandiflora, Clematis nutans and Salvia farinosa were represented by splendid flowering shoots. Gerald W. E. Loder, Esq., Wakehurst Place, Ardingly, Sussex, showed exceedingly floriferous sprays of Lagerstroemia indica, for which he received an Award of Merit in 1924, and of the interesting Pileostegia viburnumoides which received an award ten years earlier.

One of the most attractive exhibits in the hall was the circular Heath garden, so well arranged by Messrs. **Maxwell and Beale**. This charming group was well placed in the centre of the new hall. The very many species and varieties of Lings and Heathers were pleasantly broken by small specimens of Picea pungens var. Kosteri, Cupressus Fletcheri and Cedrus Deodara, and by little groups of various fruiting Berberises and Pernettya mucronata. The chief Ericas were E. vulgaris var. H. F. Beale, E. hybrida var. Williamsiana, E. vagans var. rubra and Daboecia polifolia.

Very good collections of Clematis were arranged by Messrs. **L. R. Russell, Ltd.**, and by Messrs. **Geo. Jackman and Son**. The former included plants of Crimson King, Lady Caroline Neville, Marie Boisselot, Gipsy Queen, Star of India, Beauty of Richmond, Jackmanii superba and tangutica var. obtusiuscula. The chief varieties shown by Messrs. **Geo. Jackman and Sons** were ascotiensis, The President, Gloire de St. Julien, W. E. Gladstone, Crimson King, Jackmanii, Beauty of Worcester and Princess of Wales.

Near the entrance, Messrs. **R. Wallace and Co.** had a large and effective group in which the glowing colour of a batch of Berberis Prattii placed in one corner held the eye, while in another there was a trained plant of Vitis vinifera var. purpurea bearing many bunches of little purple Grapes. Golden colour was provided by several shapely Cypresses, and the ripening leaves of a tall, slender Ginkgo biloba. Other trees and shrubs worthy of note were Rhus typhina var. laciniata of good autumn colour, Rosa Moyesii bearing numerous brilliant hips, Pyruses in variety, and Ceanothus azureus and Lespedeza Sieboldii in flowering sprays.

In the interesting group of Messrs. **J. Cheal and Sons** the shrubs in flower included various Clematises, particularly Nelly Moser, Lady Betty Balfour and Ville de Lyon, Elsholtzia Stauntonii, Kalmia rubra and Desmodium pendulifolium. The baskets of fruits of many Crabs attracted very much attention, and there were well-fruited standards of Pyrus edulis, P. Golden Gem and others. The group also contained tall, shapely Conifers, Pyracantha warleyensis and Viburnum Opulus, with many bunches of shining fruits. Messrs. **Wm. Cutbush and Son** arranged a goodly group around one of the pillars, where they displayed many Pyruses, Berberises, hardy Fuchsias, Cotoneasters and brilliantly coloured Ampelopsis Veitchii.

An extensive exhibit, set up by Mr. **R. C. Notcutt**, contained many large bushes and tall standards. He included Pyrus theifera, Pyrus floribunda var. purpurea, Pyrus Aucuparia var. pekinensis, Raphiolepis Delacourei, Ceanothus albus var. plenus, Ceanothus Georges Simon, Elsholtzia Stauntonii, Laburnum semperflorens, Althaeas in variety, Caryopteris Mastacanthus and Hydrangea paniculata var. grandiflora. Mr. W. J. **Marchant** had good colour on his Berberises, Cornus florida, Pyrus arbutifolia and Viburnums.

Many interesting and useful subjects were shown by Messrs. **Hillier and Sons**, who devoted a considerable portion of their space to well-grown Conifers. There were many Cedars, Silver Firs, Spruces and Yews, as well as Taiwania cryptomerioides, Cunninghamia Konishii, Pinus Montezumae, P. M. var. Lindleyana, and branches of Abies Webbiana, A. concolor and Pinus Ayacahuite, all bearing their cones. In their general collection we especially noted Euonymus planipes, Fremontia californica, Rosa setifolia, Rosa pomifera, many Althaeas, Prunuses, Berberises and Quercus coccinea of brilliant colour.

Tall Conifers gave dignity to the exhibit of Messrs. **George Bunyard and Co.**, who also showed a large, well-flowered bush of Viburnum Tinus, Desmodium pendulifolium, Leycesteria formosa, Lonicera Maackii, hardy Fuchsias and shrubby Veronicas in flower, and many Berberises. Standard Pyruses of good shape were grouped by Messrs. **W. Wood and Son, Ltd.**, who also included Cryptomeria japonica var. cristata, Cryptomeria japonica var. elegans, Tsuga Sargentii var. pendula and Crataegus elongata. In a well-arranged group, Messrs. **Bakers** showed many Berberises, Buddleia Fallowiana, Lonicera grata, Ceanothus Gloire de Versailles and several good Clematises.

Conifers of good shape predominated in the group of Messrs. **Fletcher Bros.**, whose chief specimens were of Pseudotsuga Douglasii var. Fletcheriana, Taxus baccata var. semper aurea, Taxus b. var. Dovastonii elegantissima, Picea excelsa var. Remontii and an especially well coloured example of Cupressus Lawsoniana var. aurea.

Large bushes of Symphoricarpus bearing plenty of white fruits were shown by Mr. H. **Hemsley**, who also included Pyracantha Lalandii, Phlomis fruticosa, Viburnum Opulus, Veronica parviflora, Tamarix hispida, Caryopteris Mastacanthus, and a good selection of Althaeas. Messrs. **Bagessens** had large specimens of Picea pungens var. Kosteri, Thuja occidentalis varieties, and Taxus baccata, with Japanese Maples and Berberises.

Bright autumn colour was present in the group of Messrs. **Waterer, Sons and Crisp** on Berberis Thunbergii, Acer japonica laciniata and Azalea pontica, while the fruiting examples included Euonymus fructo-rubra, Euonymus yedoensis, and many Pyruses. They also had graceful specimens of Acer Negundo aurea, Escallonia floribunda, various Pittosporums, Cornus Mas in fruit, Desmodium pendulifolium, Lonicera sempervirens, Hollies and Althaeas.

In an imposing group, Messrs. **A. Charlton and Sons** placed tall Conifers, Japanese Maples and standard Pyruses above Stranvaesia undulata, Desmodium pendulifolium, Cotoneaster Dielsiana, Senecio Greyii, Teucrium fruticans and many other interesting hardy shrubs. Beautiful autumn colour was present on a bush of Cercidiphyllum japonicum shown by The **Donard Nursery Co.** They also included the Tulip Tree, Enkianthus campanulatus, Cerastostigma Willmottianum, Salvia Gregii, Potentilla Farreri, many shrubby Veronicas, Spiraeas, Ericas, Olearias, Pittosporums and Prunus Pissardii and Berberis Thunbergii atropurpurea of rich colour.

The bright yellow Cassia corymbosa was well shown by Mr. G. **Reuthe** in his collection of trees and shrubs. His flowering examples also included various Hydrangeas, Berberidopsis corallina, Hoheria populnea, Magnolia grandiflora ferruginea, Lapageria rosea, Escallonia montevidensis, Araujia sericifera, Brugmansia (Datura) Knightii, Ceanothuses and Clematises. Mr. **Reuthe** also showed specimens of some of the rarer Conifers, Berberises and Rhus cotinoides of bright colour. On a table space, Messrs. **Stuart Low and Co.** displayed branches of the Fire Thorn, Berberises, Sumach, Pyruses and small Conifers. Messrs. **G. and A. Clark** set up Cydonias, Viburnum Opulus and Leycesteria formosa in fruit, with Spiraea Aitchisonii, Conifers and Berberises.

Brilliant autumn colour was shown on Azalea pontica, various Berberises, Vines and Rhus cotinoides by Mr. **T. Smith**, who also staged Lavatera assurgentiflora, Cytisus nigricans var. Carlieri and Potentillas in flower. Messrs. **D. Stewart and Co.** also staged good autumn colour as well as ornamental Crabs, small Conifers, Ericas and Clematises. Highly coloured

Vitises, Conifers, Pyracanthas, Berberises and Japanese Maples were shown by Messrs. Hollambys.

On a wall space, Messrs. Robert Veitch and Son set out an interesting collection of shrubs which included Berberis Bealei, Arbutus Andrachne, Lomatia ferruginea, Osmanthus Forrestii, Hippophae rhamnoides, various Magnolias and Conifers. A large bush of Leycesteria formosa was shown with various Berberises, Vitises and Ribes aureum, by Messrs. Patricks.

The Orpington Nurseries displayed a good selection of Conifers suitable for the rock garden with Althaeas, Cotoneasters, Berberises, Rhus typhina, and Cydonia japonica in fruit. Messrs. John Scott and Co. grouped Cydonia Wilsonii, carrying many large fruits, with various Hollies, Pyruses, Conifers and Berberises. Excellent specimen Bay trees were shown by Messrs. Robert Green and Co., and by Messrs. Harrods, Ltd.

Fruits.

At the far end of the new hall there were three splendid exhibits of fruits, easily the best of these being that set up by Mr. J. C. Allgrove. His trained trees of Plums, Peaches and Apples, all heavily fruited, were examples of the highest cultivation, the large, fan-trained trees of Plums President, Pond's Seedling and Jefferson, and smaller ones of Golden Drop and September Glory, calling forth special admiration, while the pot trees of Apples Madresfield Court and S. T. Wright, and Peach Dymond, also were grand specimens. In addition to the fruited trees, there were numerous dishes of excellent fruits of numerous Apples and Pears, all in grand condition and richly coloured. The large basket of Apple American Mother must have whetted many appetites, while other varieties represented included Cox's Orange Pippin, Celini, Peasgood's Nonesuch, Bramley's Seedling, Charles Ross, Wealthy, Rival, Ribston Pippin, Rev. W. Wilks, Ball's Pippin and Ellison's Orange, while among Pears outstanding dishes were of Marguerite Marillat, of enormous dimensions; Durondeau, Conference, Pitmaston Duchess and Beurré Hardy. There were also many attractive dishes of Plums Transparent Gage, Late Orange, Monarch and Count Althann's Gage. A very praiseworthy exhibit and well deserving the Gold Medal awarded it.

Messrs. George Bunyard and Co., Ltd., showed a representative collection of fruits of many Apples, including Cutler Grieve, James Grieve, Hormead's Pearmain, May Queen, King of the Pippins, Wealthy, Charles Ross, Ribston Pippin, wonderfully coloured; and Ellison's Orange, while they also showed good dishes of Pears Pitmaston Duchess and Conference.

Messrs. Laxton Bros. arranged baskets of numerous varieties of Apples and Pears, the background and sides of the exhibit being composed of trained cordon trees of Apples and Pears, all well fruited. Among the Apples shown, outstanding were Lord Lambourne, the new Laxton's Epicure, James Grieve, Cellini, Rival, Laxton's Superb and Charles Ross, while good dishes of Pears included Marguerite Marillat, Conference and Doyenné du Comice.

In the old hall, Mr. J. J. Kettle showed heavily fruited growths of several good late-fruiting Raspberries.

Michaelmas Daisies.

In the old hall, which was well filled with floral exhibits, Michaelmas Daisies, perhaps, provided the greatest display of colour.

The Gayborder Nurseries had a very attrac- the bed of these seasonable flowers, consisting of tall pillars of such good sorts as Maid of Athens, Mrs. G. Monro, Royal Blue, Margaret Ballard, Blue Gem and Elsa, over a groundwork of various floriferous varieties, including the Amellus varieties King George, Ultramarine, Fleuve Blue and Weinholtzii.

In the charming bank of blooms set up by Mr. F. Rich, surmounted by dainty sprays of several ericoides varieties, we noted good vases of Madame Emile Thoury, October Dawn, Rosette, Blue Eye and Miss Eisle, and baskets of several popular Amellus varieties.

Messrs. W. Wells, junr., were again well to the fore with Michaelmas Daisies, their massive wall group being very spectacular and embracing a wide range of varieties, chief among which were Barr's Pink, Margaret Ballard, Blue Gem and King of the Belgians. Among the Amellus varieties, arranged in masses along the front of the display, outstanding sorts were Ultramarine, very fine; Advance, Ethel, Charles Davis, Sonia and King George.

Mr. T. Bones had a very charmingly arranged group, the inflorescences being exceptionally clean and bright. Among his best tall-growing sorts were Una, Acme, Fairy, of very dainty and graceful habit and a special feature, and the brightly coloured Aldenham Pink; while good Amellus Asters included Ultramarine, General Pershing, Lilacina, Advance, Sonia, Bessie Chaplin and Daily Sketch.

In a charmingly arranged display, Mr. Ernest Ballard made a special feature of Silver Spray, a dainty ericoides variety, other good sorts which he showed well being Anita Ballard, very striking, associated with Maid of Athens; Beauty of Colwall, Blue Eyes, Cloudy Blue, Rosette, and Blue Gem in association with Mrs. George Monro.

In a compact but quite attractive mound of perennial Asters, Messrs. W. Wood and Son, Ltd., made a special feature of their brilliantly coloured, rather small-flowered, new variety named Red Rover, and they also included good sprays of Bright Rapture, Blue Prince, Maxima, Glowworm, very bright; October Dawn, and Muriel Chandler, a dainty, pale lilac-flowered sort of the ericoides type.

Chrysanthemums.

There were three excellent groups of early-flowering Chrysanthemums.

Messrs. Keith Luxford and Co. had lovely sheaves of Almond, Framfield White, Cranford, Uxbridge Pink, White Queen, Phoenix and Elsenham as a background to many other beautiful sorts, among which Perle Chattilonaise, Harvester, Pink Delight, Cranford Pink and Cranford Cream were much in evidence.

In a good bank of Chrysanthemums, Mr. J. W. Forsyth had pillars of fine blooms of Pink Beauty, Elsenham, Pink Delight, R. G. Collicott, Winnie Camden and Bronze Early Buttercup, and lovely vases of Alcalde, Mrs. Hutt, Armorel, Crimson Circle, Queen of the Yellows, Hollicot Yellow, Madame E. David and Harvester, while outstanding sorts in the corner group set up by Mr. W. Yandell were Phoenix, Harvest Glory, Mrs. Phil Page, Mrs. J. Pearson, Goacher's Crimson, Red Almirante and La Garonne.

Gladioli.

For so late in the season, the two large groups of Gladioli, staged by Messrs. R. H. Bath, Ltd., and Messrs. Dobbie and Co., Ltd., respectively, were especially noteworthy.

The former firm showed an extensive range of varieties, both primulinus and gandavensis, among the most striking being Schawben, Rose Ash, War, Xanthea, Flora, Athalia and Byron L. Smith, while Messrs. Dobbie and Co., Ltd. made a special feature of the variety Bertie Snow, staging many grand spikes, other good sorts which they showed well being Gertrude, Cavrick, Marvel, Dorothy Wheeler, Pfitzer's Triumph and David Airdrie.

Dahlias.

These were again much in evidence, the most striking group being that staged by Mr. J. B. Riding, who had a big bank of blooms chiefly of large-flowered Decorative sorts. Varieties which he showed exceptionally well included Amulet, W. D. Cartwright, Maud Johnson, Jersey Beauty, Grace Curling and Mabel Lawrence.

Mr. Charles Turner staged a fairly representative collection of Dahlias, as also did Messrs. G. W. Miller, who associated them with various seasonable hardy border flowers.

Outstanding varieties in the group of Dahlias set up by Messrs. H. H. Langridge and Co. included Couldson, Topaz and Jersey Beauty, while in the attractive exhibit arranged by Messrs. Jarman and Co., Jack Hobbs, Trentonian, Mabel Lawrence, Amun Ra, Peerless, Berengaria and Ullswater were specially worthy of note.

Carnations.

In a small but not unattractive group of Carnations, Messrs. Stuart Low and Co. showed charming vases of good blooms of Countess of Harewood, Sonny, Eileen Low, Sheila Greer, Happidais and others; while Messrs. Allwood Bros. included Wivelsfield White, Spectrum, Laddie, Topsy and other good sorts in their exhibit of perpetual-flowering Carnations, and also arranged a group of Dianthus Allwoodii varieties, prominent among which were Rachel, Barbara, Marion and Elizabeth.

Roses.

Several excellent groups of Roses were staged in the old hall and added greatly to the general bright effect.

Messrs. D. Prior and Son set up a representative collection which included specially good examples of Etoile de Hollande, Betty Uprichard, Madame Butterfly and Souvenir de Madame Boulet; while Messrs. Wheatcroft Bros. had excellent vases of many popular sorts, with Peter Pan and The Princess Elizabeth as special features. Mr. J. H. Pemberton also had a bright group of many good sorts.

In their representative group, Messrs. Alex. Dickson and Son, Ltd., had a lovely basket of good blooms of Flamingo, and very effective pillars of Betty Uprichard, Adele Crofton, Canary and Lady Inchiquin; while Messrs. Ben. R. Cant and Sons also arranged a bright and representative group of Roses.

Miscellaneous Exhibits.

Mr. George G. Whitelegg arranged a charming rock garden on tabling, with dwarf Conifers in variety suitably placed and plantings of various late-flowering hybrid alpine Pinks, Gentiana sino-ornata and G. Farreri, Zauschneria californica var. splendens, Dryas Sundermannii, Oenothera speciosa var. rosea, and other suitable flowering subjects.

Another attractive rock garden was that laid out by Mr. George E. P. Wood, who used, besides dwarf Conifers and suitable shrubs, such flowering subjects as Gazanias, Delphinium sinense, very bright; Ceratostigma plumbaginoides, and Verbena venosa; while Mr. H. Hemsley, in his rock garden, had shrubby Veronicas in flower; a well-fruited specimen of Cotoneaster horizontalis, and small groups of Origanum hybridum, Campanula Warley White, Cyclamen neapolitanum, alpine Pinks in variety, Viola Arkwright's Ruby, Nertera depressa covered with its orange fruits; Campanula muralis and various creeping Verbenas.

Messrs. Walter Blom and Son, Ltd., staged an extensive collection of various forms of Colchicum autumnale, while Messrs. Reamsbottom and Co. exhibited St. Brigid Anemones in association with Delphinium sinense. Mr. John Golding showed many vases of his variety of Scabiosa caucasica called goldingensis; Messrs. Isaac House and Son had a charmingly arranged group of the many fine forms of Scabiosa caucasica; the Misses K. and E. Hopkins had a mixed collection of herbaceous flowers, including the charming pink-flowered Aster Esther, of the ericoides section; and Messrs. E. J. Redgrove and Son, in their mixed collection of seasonable flowers, showed Michaelmas Daisies in variety, Kniphofias, late spikes of Delphiniums, Heleniums, Helianthus Monarch, and Lupins.

Mr. Amos Perry had an interesting mixed group containing, among other things, Solidago Gold Elf, Salvia azurea var. grandiflora, Pentstemon barbata, Kniphofias and Anthemis tinctoria, Perry's variety, with several alpine and other plants.

Mr. Gavin Jones showed Michaelmas Daisies, the rosy-purple-flowered Vernonia arkansana, Caryopterus Mastacanthus, alpine plants and various other subjects in an interesting group; while Mr. S. J. Goodliffe, besides showing various good Michaelmas Daisies, had fruiting shrubs, including Barberries and Cotoneaster microphylla, and flowering shrubs in Ceanothus azureus, Potentilla fruticosa var. Farreri, and the purple-foliaged Prunus Pissardii, Hazledene variety.

Messrs. B. Ladhams, Ltd. staged fruiting shrubs in association with Lobelias in variety, Asters, Salvia uliginosa, Eryngium Violetta, Montbretia King Edmund, and various Sidalceas. Messrs. G. and A. Clark and Messrs. Rich and Cooling, also had representative groups of herbaceous flowers; and Messrs. E. F. Fairbairn and Sons staged herbaceous Phloxes in many good sorts.

THIRD AUTUMN SHOW.

October 8 and 9.—In continuance of the policy of holding a series of special Autumn Shows, the Fruit and Vegetable Show was held at Westminster on these dates. The exhibits of fruits were all set out in the new Horticultural Hall, while the vegetables and several exhibits of autumn flowers were displayed in the old hall. The fruits generally were of exceedingly high quality, and the competition was equal to the average of other years, but we missed the many large competitive exhibits of hardy fruits that nurserymen staged for so many years at the Autumn Fruit Shows. But there were two particularly fine collections of pot-grown fruits, and several very interesting exhibits of such rarities at shows as the Cape Gooseberry and Banana. It was interesting to note that in this year, when the autumn colour of foliage is lacking, many of the Apples were unusually highly coloured. In the old hall there were several exceedingly good collections of vegetables and, while, no doubt due to the season, the competitive classes were not so well filled as usual, the quality was very creditable.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Frederick J. Hanbury, Mr. Richard G. Thwaites, Mr. J. E. Shill, Mr. H. G. Alexander, Mr. Charles H. Curtis, Mr. J. Wilson Potter, Mr. Stuart Low and Mr. A. Dye.

There were no groups before this Committee, and only two plants, both of which received recognition.

First Class Certificate.

Cattleya Heros (*C. Heliodor* × *C. Sunbeam*).—A fine addition to the brilliant autumn-flowering section of hybrids. The spike carried three glorious flowers of fair size and good form. The sepals and petals are golden-yellow, while the rounded lip is heavily veined with gold on an orange and cerise ground, with a ruby-coloured apex. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Award of Merit.

Sophro-Laelio-Cattleya Jean (*Sophronitis grandiflora* × *Laelio-Cattleya Orange Blossom*).—A beautiful and brilliant new hybrid with a flattish flower of bright salmon-orange colour. The lip is clear yellow in the throat, with deep salmon-orange on the side lobes and at the slightly frilled apex. Shown by Messrs. H. G. Alexander, Ltd.

Floral Committee.

Present: Section A.—Mr. J. F. McLeod (in the chair), Mr. Arthur Turner, Mr. A. E. Vasey, Mr. D. B. Crane, Mr. James B. Riding, Mr. J. T. West, Mr. Hugh A. Dickson, Mr. W. B. Gingell, Mr. William Howe, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. R. Findlay, Mr. Charles E. Pearson, Mr. Courtney Page and Mr. W. D. Cartwright, Secretary.

Present: Section B.—Mr. E. A. Bowles (in the chair), Mr. George Yeld, Mr. W. G. Baker, Sir William Lawrence, Bart., Mr. L. R. Russell, Mr. A. Bedford, Mr. T. W. Taylor, Mr. F. G. Preston, Mr. Mark Fenwick, Mr. R. C. Notcutt, Mr. T. Hay, Mr. Hiatt C. Baker and Mr. N. K. Gould, Secretary.

At the meeting of Section A Committee, the members bade farewell to Mr. J. F. McLeod, who is leaving London and taking up residence in Scotland. Mr. William Howe conveyed to Mr. McLeod the good wishes of the Committee, and expressed regret that his long connection with the Floral Committee would be severed.

Awards of Merit.

Phaseolus Caracalla.—This curious and not unbeautiful member of the Bean family was introduced from India in 1690. It is a strong-growing climber and needs cultivation under glass. The large flowers are borne in stiff racemes, and the colour is white, cream and purplish-blue. The attractive flowers are of large size, and their great attraction lies in the abnormal development and spiral twisting of the vexillium. Shown by Mrs. Roper, Forde Abbey, Chard, Somerset.

Zephyranthes Atamasco.—The Atamasco Lily, introduced from Virginia in 1629, is a well-known bulbous plant, and one that was figured in *Bot. Mag.*, t. 239, under the name of Amaryllis Atamasco. Three hundred years have elapsed since its introduction, so the award given was something in the nature of a long-deferred birthday present. Z. Atamasco has long, linear, deep green leaves and erect, elongated, Crocus-like flowers that are white, with a green base and golden anthers. It is a good hardy subject for the rock garden, a special border, or the cold greenhouse. Shown by Sir William Lawrence Bart. (gr. Mr. W. Everatt), Burford, Dorking.

Chrysanthemum Snowflake.—A fine pure white variety, bearing shapely flowers in long, elegant sprays.

Chrysanthemum Cavalier.—A very useful early-flowering variety of graceful form; terra-cotta, with gold tips. These two varieties were shown by Mr. H. Shoesmith, junr.

For Trial at Wisley.

The following were selected for trial at Wisley.

Chrysanthemum Pink Profusion.—Small, pink flowers, carried freely in long sprays. From Mr. H. Shoesmith, junr.

Dahlia Sunny Clacton.—A single variety, white, with a wide band of scarlet down each side of every segment; but the colour ends abruptly and does not meet at the end of the ray florets. From Mr. E. Knight, Clacton.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (in the chair), Mr. E. A. Bunyard, Mr. H. S. Rivers, Mr. W. H. Divers, Mr. F. Bostock, Mr. J. Wilson, Mr. J. Basham, Mr. R. H. Hall, Mr. H. Markham, Mr. A. C. Smith, Mr. W. F. Giles, Mr. A. Bullock, Mr. P. D. Tuckett, Mr. F. Jordan, Mr. T. Pateman, Mr. W. J. Earl, Mr. A. Poupart, Sir W. G. Lobjoit, Mr. G. Woodward, Mr. E. A. Laxton, Mr. E. Neal, Mr. A. W. Metcalfe, Mr. W. Poupart, Mr. J. G. Weston, Mr. J. C. Allgrove, and Mr. A. N. Rawes, Secretary.

Award of Merit.

Apple Howgate Wonder.—Among the several new Apples shown before this Committee, this received recognition, and was considered worthy of the above award. It was also recommended for inclusion in the commercial fruit trials at Wisley. It is a large culinary Apple, of the Beauty of Kent type; round-conical in shape, about four inches across and about the same in depth. The eye is closed and set in a ribbed basin of medium size, while the very short, thick stalk is set in a broad and deep cavity. The flesh is very firm; the colour yellowish-green, flushed and streaked with red on the exposed side. Shown by Mr. George Wrathen, 4, Hope Cottages, Howgate Lane, Bembridge, Isle of Wight.

The Fruit Show.

Dessert Fruit Classes.

There were nine collections of nine dishes of ripe dessert fruits, and the first prize was awarded to the Duke of Newcastle (gr. Mr. S. Barker), Clumber, Worksop, for an exhibit of which the most noteworthy feature was the beautiful colouring of the Peaches and Apples. The bunches of Muscat of Alexandria Grapes were only of moderate quality. The Apples were Cox's Orange Pippin and Lady Palmerston, which, with Sea Eagle Peach, Souvenir du Congrès Pear and Universe Melon were of very high quality. The second prize was awarded to the Rt. Hon. Lord Swaythling (gr. Mr. F. J. Rose), Townhill Park, Southampton, whose Apples and Pears were excellent. The varieties were Wealthy and Cox's Orange Pippin Apples and Louise Bonne of Jersey Pears. There were also highly coloured fruits of the Nectarine Peach and very large bunches of Mrs. Pearson and Mrs. Pince Grapes. In the third prize exhibit of T. S. Hall, Esq. (gr. Mr. J. Richardson), Cricket St. Thomes, Chard, there were the best Muscat of Alexandra Grapes in the class and the dishes of Barrington Peach and Cox's Orange Pippin Apple were also of high quality. Mrs. A. A. Hornby Lewis (gr. Mr. A. E. Friend), Danesbury Park, Marlow, who was fourth, had very good dishes of Charles Ross Apple and Reine Claude de Bavay Plum.

Although there were only two exhibits of six dishes of dessert fruits they were of very good quality. The first prize was won by Viscount Hambledon (gr. Mr. W. Turnham), Greenlands, Henley-on-Thames, who showed Muscat of Alexandria and Appley Towers Grapes, Lady Palmerston Peaches of beautiful orange colouring, Cox's Orange Pippin and Ellison's Orange Apples, and Emerald Gem Melon. Lt.-Col. F. J. B. Wingfield Digby, D.S.O. (gr. Mr. E. Hill), Sherborne Castle, Dorset, had, in his second prize exhibit, excellent bunches of Gros Colmar Grapes, Golden Eagle and Sea Eagle Peaches.

Grape Classes.

The exhibits of Grapes occupied considerable space, and while the quality generally was good, the bunches of Muscat of Alexandria were not equal to those of most former years.

Of the three exhibits of four bunches, the best was shown by Lord Hotham (gr. Mr. J. S. Coates), Dalton Hall, Beverley, who showed Muscat Seedling as a large bunch of rounded, amber berries, Madresfield Court, Muscat Hamburgh and particularly well-coloured Gros Colmar. The Duke of Newcastle was second, with large bunches of Gros Guillaume, Mrs. Pince, of good colour, and Muscat of Alexandria. T. S. Hall, Esq., who was third, had good bunches of Muscat of Alexandria and Alicante. There were six exhibits of two bunches each of a white and a black variety. Lord Hambledon was first with excellent Muscat of Alexandria and large bunches of Appley Towers. Miss Durning Lawrence, King's Ride, Ascot, was second with Muscat of Alexandria and Alicante, and C. B. O. Clarke, Esq. (gr. Mr. J. Kidd), Wistern Park, Steyning, was third.

The following classes required two bunches each of specified varieties. G. Meyer, Esq. (gr. Mr. R. Cottam), Wistler's Wood, Woldingham, was first, with well-coloured bunches of Lady Downes; the second prize was not awarded. Lord Swaythling and G. Meyer, Esq., were first and second, respectively, with large bunches of Mrs. Pince. Ten exhibitors staged Alicante and all had bunches of considerable merit; the Hon. Mrs. Cufton (gr. Mr. H. H. Brown), Castle Hill, Englefield Green, was first with almost perfect bunches and Lord Hotham was a good second. Lord Hotham, the only exhibitor, was awarded the first prize for very good bunches of Madresfield Court Grapes. Four exhibitors staged Appley Towers, and the first prize was awarded to the Duke of Newcastle for very good bunches, while C. G. A. Nix, Esq. (gr. Mr. E. Neal), Tilgate, Surrey, was second with smaller, but deeply coloured bunches. In the class for any other black Grape, C. J. A. Nix, Esq., was first, with reddish Muscat Hamburgh, and Mrs. F. de Lisle John (gr. Mr. R. Currie), Mereworth Lawn, Boro Green, Kent, was second, with smaller but deeply coloured Black Hamburgh.

The leading bunches of Muscat of Alexandria Grapes in the two bunch class were of better quality than in the dessert fruit classes. Viscount Hambledon was first, and Miss. Durning Lawrence was second, with good bunches. There were six exhibits of any other white Grape, and Lord Hotham was an easy first, with excellent bunches of Muscat Seedling. Sir William Lawrence, Bart., Burford, Dorking was second, with Chasselas Napoleon.

Melons were particularly good, and of the nine shown the very best was Lord Swaythling's Blenheim Orange. The Hon. Mrs. Cufton was second with Countess, and Mrs. Hornby Lewis was third with Hero of Lockinge.

Outdoor Fruit Classes.

The best collection of one dish each of thirty varieties of hardy fruits was staged by Major C. A. Drummond (gr. Mr. L. H. Smith), Cadland Park, Southampton, and this was especially noteworthy for the shapely and highly coloured dishes of Apples Kondine, Herring's Pippin, Cox's Orange Pippin, Charles Ross and James Grieve. He also showed, in Doyenné Bussoch, Triomphe de Vienne and Marguerite Marillat, exceedingly good Pears. There was also a fine dish of Thomas Rivers Peaches, and one of a green Fig. Lord Swaythling was a good second, and he showed excellent Peasgood's Nonesuch and Gascoyne's Scarlet Apples. Souvenir du Congrès and Marie Louise Pears, Late Duke Cherries and Coe's Golden Drop Plums. Lieut.-Col. Wingfield Digby was third.

In the class for twelve varieties of hardy fruits, Sir Randolf Baker, Bart. (gr. Mr. A. E. Usher), Ranston, Blandford, was first, with a magnificent exhibit. His dishes of Wealthy, Peasgood's Nonesuch and Cox's Orange Pippin Apples were of the ideal size and beautifully coloured. He also included President Roosevelt and Doyenné du Comice Pears, and Rivers' Late Orange and Coe's Golden Drop Plums of high quality. J. H. London, Esq. (gr. Mr. J. Bond), Olantigh, Wye, was second, and he staged Charles Ross and Peasgood's Nonesuch Apples, Triomphe de Vienne Pears, and Late Orange Plums, of excellent quality.

The two exhibits of twenty-four varieties of Apples were also of considerable merit. Major C. A. Drummond was first, and he had particularly good dishes of Ribston Pippin, James Grieve, Allington Pippin, Charles Ross and Kondine dessert Apples, and of the culinary varieties The Queen, Rev. W. Wilks, Cox's Pomona and Peasgood's Nonesuch. F. C. Stoop, Esq. (gr. Mr. G. Carpenter), West Hall, Byfleet, was a good second, and his dessert varieties included Charles Ross and Benn's Red of high colour, while the very best culinary sorts were Bismarck, Warner's King and Tom Putt. Four exhibitors staged twelve varieties, and here again Sir Randolf Baker, Bart., was first, with beautifully coloured Rival and Charles Ross of the dessert varieties, while his dishes of Mere de Ménage, Rev. W. Wilks and Peasgood's Nonesuch were ideal. J. H. London, Esq., who was second, also staged dessert Apples of high colour. His varieties included Rival, Charles Ross and Gascoyne's Scarlet and he had Lord Derby and Loddington among his cooking Apples. C. G. A. Nix, Esq., was third.

There was a good class of six dishes of cooking Apples where Major C. A. Drummond, who included Mere de Ménage, Warner's King, Lane's Prince Albert and Lady Henniker of excellent appearance, was first, and the Earl of Bessborough (gr. Mr. T. A. Tomalin), Stansted Park, Emsworth, was a good second, with splendid dishes of Gascoyne's Scarlet, Herring's Pippin, Charles Eyre and other good sorts.

The fifteen exhibits of six dessert varieties were admirable in their even shape and typical colour. Mr. J. A. Stidston, Bishopsteignton, Devon, was first, and he included excellent dishes of Lord Lambourne, James Grieve Charles Ross and Wealthy. H. C. Sutton, Esq. (gr. Mr. A. D. Smith), Newbury, had, in his good second prize exhibit, Rival, The Houblon and Charles Ross of high colour.

A gratifying number of exhibitors staged eighteen dishes of dessert Pears, and all were of considerable quality. The very best exhibit was staged by Lt.-Col. Wingfield Digby, whose best dishes were of Beurré Hardy, Souvenir du Congres, Beurró Bosc, Doyenné du Comice and St. Luke. Mrs. Winterbottom showed, in a good second prize exhibit, grand dishes of Doyenné Bussoch, Marguerite Marillat, Noveau Poiteau and Beurré Alex. Lucas. Although there were only two exhibits of nine dishes of dessert Pears, they were of excellent quality. Sir Randolf Baker, Bart., included, in his first prize exhibit, Durondeau, Doyenné du Comice, President Roosevelt and Beurró Baltet Pére, of fine appearance. The Hon. Henry Coventry (gr. Mr. J. J. Jackson), Lendring Hall, Stoke-by-Wayend, was second, and his best dishes were of Charmontel, Charles Ernest, Doyenné Bussoch and Beurré Hardy.

There were eight exhibits of three dishes of cooking Pears. Lt.-Col. Wingfield Digby was first with Beurré Clairgeau, Catillac and King Edward. Mrs. Winterbottam (gr. Mr. J. Brown), Oakley Place, East Grinstead, included Bellisime d'Hiver and Beurré Clairgeau in a good second prize exhibit.

Plums were an especially good class, and the eleven dishes were all of praiseworthy quality. Lady Mary Morrison (gr. Mr. H. H. Mills), Fonthill House, Tisbury, had, in splendid fruits of Late Orange, Coe's Golden Drop and President, the best three dishes. Major Drummond, who was second, showed excellent Coe's Golden Drop and Grand Duke. There were no fewer than twenty single dishes of Plums. Sir Randolf Baker, Bart., showed, in his first prize dish of Jeffersons, the best Plums in the show, and Lady Mary Morrison was second, with almost as good fruits of the variety President. Damsons and/or Bullaces were also a strong class. W. H. Cohen, Esq. (gr. Mr. A. V. Skinner), Amersfort Gardens, Berkhamsted, was first with King of Damsons, and Lt.-Col. Sir Walter Halsey, Bart. (gr. Mr. T. Avery), Gaddesdon Place, Hemel Hempstead, was second, with rich yellow fruits of Langley Bullace.

The class for Raspberries brought six good dishes. Capt. R. B. Brassey (gr. Mr. G. J. Quinn), Cottesbrooke Hall, Northampton, was first with the variety Lloyd George, and Brigadier-General R. G. A. Howard Orpee, M.C., D.S.O. (gr. Mr. F. G. Cooke), Stoke Place, Slough, was second with a very good dish of Queen Alexandra.

Market Growers' Classes.

Although there were only two exhibits in each of the classes for Grapes in chip baskets, they were of exceedingly good quality. Messrs. J. Almond and Son, Effingham, won both first prizes. Their white Grapes were splendid bunches of Muscat of Alexandria, and the black were equally good samples of Alicante. Mr. A. G. Bury, Byfleet, was a good second in both classes.

The judges pointed the several exhibits of four British standard boxes of Cox's Orange Pippin Apples. The quality was not so high as in former years, and the first prize exhibit of Mr. H. J. Russell, Hatfield Peverel, obtained only 71½ points from a possible 100. The Reading University College was second.

The class for four similar boxes of any other dessert Apple was particularly good, and here the Reading University College was first with boxes of Worcester Pearmain Apples of such dazzling colour and general excellence that, if pointed, would certainly have approximated the maximum for all qualities. Mr. Glover Long, Higham, was second with exceedingly good boxes of Charles Ross.

The class for four boxes of Bramley's Seedling brought very good exhibits, and here Messrs. W. Brice and Son were first with admirable boxes, and Mr. Glover Long was a good second. Splendid Newton Wonder, shown by Messrs. W. Brice and Son, were first in the class for four boxes of any other cooking variety, and Mr. Glover Long was second with nearly as good Lord Derby. The many three one-layer boxes of Cox's Orange Pippin presented a tempting appearance. Mr. H. G. Evans, Hatfield Peverel, was first, and Mr. J. B. Douglas, also of Hatfield Peverel, was second. In the similar class for any other dessert variety, Mr. Glover Long was first, with brilliant fruits of Worcester Pearmain, and the Reading University College was a close second with delicately coloured James Grieve.

Pears were also well shown. Messrs. F. and J. Neave, Mackendale, had the best three one-layer boxes of Conference, and Messrs. W. Brice and Sons were a close second. The best three boxes of Doyenné du Comice were shown by Messrs. F. and J. Neave and Messrs. W. Brice and Son were again second, both showing first-rate fruits admirably packed.

⁂ The remainder of the report of this show will appear in our next issue. Eds.

NATIONAL CHRYSANTHEMUM.

The Floral Committee met at the Royal Horticultural Hall, on Monday, October 7, and made the following awards :—

Golden Chestnut. *II.*1b.—A rich chestnut variety, with golden reverse ; the florets are broad, slightly cupped, and make up a substantial bloom. This is stated to be a good variety for garden decoration ; about two feet tall.

Brassy. *II.* 1c.—In this bright chestnut, gold-tipped variety, the blooms are of medium size but elegant form ; good stems and foliage.

Cactus. *II.* 1b.—A fairly large, elegant Japanese variety with pointed florets ; chestnut-bronze, with gold reverse. These three varieties were shown by Mr. J. Barrell.

Snowflake. *II.* 1c.—A beautiful and elegant pure white variety with blooms of moderate size borne in long, graceful sprays ; very free.

Nelrose. *II* 1b.—This very distinct variety carries fairly large and substantial blooms composed of broad, stiff florets that incurve a little at the tips. The colour is deep lilac-pink of a shade seen in some of the darker Lilacs.

Cavalier. *II.* 1b.—An effective variety of fine form and clean colour ; bronzy-terra-cotta, with small gold points. These last three were shown by Mr. H. Shoesmith, junr.

ALDERLEY EDGE AND WILMSLOW HORTICULTURAL AND ROSE.

Early in September, the above Society brought its summer session to a close with a visit to Alderley Park, Chelford, and the party, which numbered nearly fifty, was conducted over the gardens by Mr. Summerfield, the gardener.

A notable feature of Alderley Park Gardens is the extensive walled-in garden, some seven or eight acres being so enclosed, the whole being divided into two portions by a central wall. One half, known as the Pond Garden, is laid out as an ornamental flower garden, and the other is devoted to fruit and vegetable culture ; in both sections the visitors found much to admire, and high culture was evidenced.

The spacious lawns, with specimen Cedars and other Conifers here and there, were inspected, and the wild garden, with its large plantings of Rhododendrons and other suitable subjects, was also much admired, while the magnificent views from the lawns across the Park in many directions presented scenes best described as highest examples of typical English landscape.

At the close of the visit, Mr. Summerfield and Mr. Williams, who also acted as a guide, were thanked for their kindly interest and services, and the members expressed their gratitude to Lord and Lady Stanley for permission to inspect the gardens.

Obituary.

W. Clark.—Born in 1857, Mr. Clark served his apprenticeship at Melville House, Fife, and afterwards gained experience in the gardens at Dunlop House, Wishaw House and Lennox Castle, before he became foreman at Broadmeadows, Selkirkshire. After spending some time at Altyre, he became head gardener to J. Roberts, Esq., at Bannerfield, Selkirk, where he continued to serve under the son, F. Roberts, Esq., until June of the present year, when he retired owing to ill-health. He passed away on September 28, at the age of seventy-one years. Mr. Clark was a capable gardener, and was particularly successful in the cultivation and raising of Odontoglossums and Chrysanthemums, at Bannerfield, and at one time he was a frequent exhibitor at the Edinburgh shows. He leaves a widow, eight daughters and three sons to mourn his loss. One of his sons is Mr. W. Clark, Superintendent of the Public Parks and Gardens at Southport, and Superintendent of the Southport Show.

ANSWERS TO CORRESPONDENTS.

Begonias Failing.—*C. G.* We found no trace of any disease organisms on the Begonia plant. The trouble may be partly due to some cultural defect, such as faulty watering during the recent bright weather. Sections were made of the main stem, petioles and main veins, and it would appear that there is something in the compost, or added to the soil in watering, that is distasteful to the plants. Repot the plants in fresh compost and pay attention to the source from which you derive your water.

Chrysanthemums Diseased.—*H. S. F.* and *A. Y.*—The specimens of diseased Chrysanthemums submitted for examination were insufficient for the purpose of diagnosing the trouble. Only shoots were received, and as the centre of infection may probably be traced to either the roots or the lower part of the stem, it is essential to send an entire plant before we can report on the trouble.

Chrysanthemum Infested with Insects.—*E. M.* The Chrysanthemum foliage has been infested with thrips and aphides, numerous moult skins of both pests being present on the lower surface of the foliage. The plants also appear to be suffering from "scorch," but we would prefer to examine an entire plant before we can definitely state that this is the sole trouble.

Failure of Apples.—*W. J. G.* If you had given us a little more information about your soil, how it was prepared, the position and the way the trees were planted, we might have been better able to help you. The wood sent shows the trees are suffering from lack of nourishment, and although basic slag and potash are a great help towards success, a dressing of farmyard manure would have been of much more value in your case. See that the ground is not suffering from lack of lime, and give a good dressing of decayed manure around each tree, to be lightly turned in, or to be left on the surface if the trees are on grass, to be followed with the same treatment the following year. The Tomato sent is of no special value unless you can get a nurseryman to list it.

Gladioli Diseased.—*A. W. M.*, *K.*, and *E. M.* The samples of Gladioli corms received show that they are affected with the Fusarium Wilt Disease. (See reply to *H. P.* in *The Gardeners' Chronicle* of September 14.)

Grapes Unsatisfactory.—*W. E. B.* The Grapes sent for examination were smashed in transit, and the only trouble we could detect was shanking, which would cause the berries to become soft. As the vine is old and partially in an outside border, this may partly be the cause of the trouble, and it would hardly pay to renovate or renew the border. A Black Hamburgh vine, being hardier, would not suffer to the same extent, and would carry twenty bunches easily. If you took up a young rod from the base you could remove the old vine in a year or two and prevent a recurrence of the trouble.

Muscat Grapes Unhealthy.—*F. T. B.* The scorched appearance of your Muscat leaves is entirely due to red spider eating all the nourishment out of them, and not to scalding. If you examine the leaves carefully through a lens you will find they are infested with red spider and their eggs, and naturally the oldest leaves will fall first. You may have checked the spider early in the season, and would, no doubt, have destroyed the eggs if you had persevered with your treatment. Carefully wash the house and dress the vines with Gishurst Compound during the winter months, and the walls with hot lime-wash and sulphur. There was a large amount of shanking among the berries. It is difficult to state how this has arisen; it may be caused by over-cropping, destruction of the foliage by red spider, checks and chills, or it may be caused by the border becoming dry at the time when the vines most need water. In your case it cannot have resulted from the roots getting into cold subsoil, or the border becoming sour, or the result of any one special cause, but a variety of concurrent causes. Avoid any of the above evils and you should not be troubled further with shanking.

Muscat Grapes.—*J. D.* As the bunch of Muscat of Alexandria Grapes was in an advanced state of fermentation on arrival, it was difficult to form a correct opinion of the rust on the berries. There are many causes to account for a rusty appearance, and when once it is produced there is no remedy. It is caused when the skin is young and tender and generally before the Grapes have stoned. Cold currents of air are most suspected, especially when the vinery is very hot, close and moist, and then suddenly, on some bright morning, cold air is admitted too freely; the use of sulphur before the stoning period; and overheated pipes which produce a parched atmosphere, especially in early houses where a good deal of firing is used. Scorching and scalding of the leaves and berries are both caused by the badly arranged or late ventilation while the atmosphere and often the bunches themselves are charged with moisture. Muscat of Alexandria and Lady Downe's are varieties most subjects to rust disfigurement, especially if grown in a mixed collection. The temperature should never be allowed to fall too low towards early morning. Always endeavour to maintain a slightly drier atmosphere before the stoning period, by admitting a little more air early on fine mornings, thus preventing a close, warm atmosphere saturated with moisture. After stoning, plenty of moisture must be provided, as with its immense leaf surface the vine needs a constant supply of water at the roots.

Names of Fruits.—*Altho.* Pear Autumn Bergamot.—*J. C.* Apples: 1, probably Wealthy; 2, Bismarck; 3, Allington Pippin; 4, not in character, probably American Mother; 5, also out of character, probably Lane's Prince Albert.

Names of Plants.—*G. B.* Amaryllis Belladonna.—*G.* 1, 2 and 3, Pittosporum tenuifolium; 4 and 5, P. eugenioides; 6, 7, 8 and 9, P. tenuifolium; 10 (? number missing), P. crassifolium or P. Ralphii, but the specimen was very shrivelled; P. crassifolium has a revolute margin to the leaves.—*I.* Tsuga Brunoniana.

Vine Roots Unhealthy.—*H. N.* The vine roots are free from Phylloxera infection. They are, however, very unhealthy indicative of having grown in a stagnant border. We suggest that you carry out the suggestions given in answer to your first enquiry.

Abstract Published.

316,122.—Manures.—Gardner, D., 37, Rue Charles Floquet, Reuil, Seine-et-Oise, France.

Titanium compounds, other than nitrides and free from or containing only traces of iron, are added to fertilisers containing fixed nitrogen, potassium salts or phosphates. The titanium compounds may be associated with manganese compounds, and are used in small, preferably catalytic, proportions only. The titanium compounds may also be associated with silica, and lime, baryta, or magnesia. Titanium dioxide, calcium or other titanates, sphene, ores containing titanium and manganese; a slag having the formula $MgOTiO_2SiO_2$, obtained as described in Specification 207,247, and other slags containing manganese silicate and titanate, also obtained as described in the same specification, are mentioned as suitable titanium compounds. In one example, potassium sulphate is mixed with sphene; in a second, ammonium sulphate is mixed with magnesia; silica and titanium dioxide; and in a third, superphosphate is mixed with titanium dioxode and manganese dioxide.

MARKETS.

COVENT GARDEN, Tuesday, October 8, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—The general conditions already indicate some improvement in business in this department, and prices were firmer this morning for best quality blooms, especially for Carnations, Roses, Lilium longiflorum, Gardenias, Stephanotis and Lapagerias. Chrysanthemum blooms of medium size are still plentiful, but special white blooms continue limited in quantity; a few large blooms of white, pink and yellow are now on sale, but are so far in little demand at 10s. to 12s. per dozen. Michaelmas Daisies and Gladioli are now finishing, also good Physalis. Single Violets are arriving in good condition, also single Anemones. Richardias are now on sale in fair condition. The French season of Solanum berries, Capsicums and bunches of Acacia (Mimosa) has commenced. Business begins to show some activity in the pot plant section, the chief attraction being flowering plants of Erica nivalis and E. gracilis, in excellent condition. Other lines are Chrysanthemums and Solanums. Ferns and Palms, all sizes, are now much finer in quality and are selling more freely; some well-grown Physalis in forty-eights are very attractive just now for decorative purposes.

Remarks.—There has been some falling off in the volume of produce available, as compared with recent quantities. The demand, however, is fairly stable and price levels all round have shown no undue fluctuations. In the orchard fruit section, best Apples are still making quite good prices, and the recent glut of "drop" and second grade fruits has disappeared, bringing much firmer conditions. There are some imported Apples available, mainly from North America, the best of which are selling freely. A few good English Pears are now meeting a better demand and sell well. In the hothouse fruit department, the tone is good, and the Grapes, Peaches, Nectarines, and Melons are selling moderately well. English Tomatos Show an improved business and good marks are being inquired for, while better conditions are ruling for Jersey outdoor Tomatos. The Cucumber trade is firm and better prices are the rule. Hothouse Beans show a gradual rise in prices, and this section will probably continue to do well through the winter. Some Beans from Madeira are now on the market, and have sold well this week. Cultivated Mushrooms continue to sell freely at higher rates, and prices are good, even for field Mushrooms. Except for Damsons and Prunes, the Plum crop has practically finished what should be a satisfactory season from a grower's point of view. Green vegetables are selling fairly well, as are all salads. The Potato trade is a shade firmer, with some expansion in the demand.

GLASGOW.

The markets were quiet and uninteresting during the past week. Spray Chrysanthemums varied in price from 2½d. to 6d. per bunch, all colours, and disbudded blooms were worth from 8d. to 1s. 3d. for 6's; while specials made 1s. 6d. to 2s. Carnations ranged from 2s. to 3s. 6d. per dozen; Roses, 2s to 3s 3d.; Calendula, 1s. 6d. to 2s. per dozen bunches; Gladioli, 2d. to 4d. for 3's; Heather, 8d. per bunch; Richardias, 3s. 6d. to 4s. 6d.; Smilax, short, 9d.; medium, 1s. 3d. and long, 1s. 6d.

In the fruit section, American Apples were quoted 15s. per case for Wealthy; 13s. to 14s. 6d. for Gravenstein; and Virginia York Imperials, in barrels, 25s. English cooking Apples sold at 12s. 6d. per half-barrel; Victoria Plums, 3d. to 8d. per lb.; Burnets, 1½d. and 2d.; Damsons, 3½d. and 4d.; hothouse Grapes, Gros Colmar, 3s. 6d. per lb., Muscats, 4s. 6d.; South African Oranges, 15s. to 20s. per case; Sunkist (Californian), 18s. to 22s.

Tomatos realised 5½d. to 7d. per lb.; Cucumbers, 4s. to 5s. per dozen; Cauliflowers, 2s. to 4s.; Lettuces, 2s.; and French Beans, 9d. to 1s. per lb.

GARDENING APPOINTMENTS.

Mr. J. C. Jolley, for the past two years gardener at The Cedars, Barwell, Leicester, and previously for fourteen years gardener at Blackdow Hill, Leamington, as gardener to E. O. C. Howells Esq., Haynstone Gilbert Hill Road, Coventry. [Thanks for 2s. for R.G.O.F. Box.—Eds.].

Mr. George H. Young, for the past six-and-a-half years at The Elms, Rudgeway, as gardener, to H. G. Bush, Esq., at The Grove, Alveston, near Bristol.

CATALOGUES RECEIVED.

Clibrans, Ltd., Altrincham.—Trees, Shrubs and Climbing Plants; Mushroom culture; Herbaceous and Alpine Plants.

TRADE NOTE.

Patents and Trade Marks.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle.*

BINDING CASES
for the
GARDENERS' CHRONICLE

Price of each case (½-year) 5s. 6d. post free.

When it comes to looking up a reference, there is all the difference between a set of papers lying about loose, half of them missing and the rest torn and dirty, and a set neatly attached in a binder, protected from dirt by a stiff cover, all in order, and yet so ingeniously placed that each number can be detached in a moment. This latter desirable state of affairs can be secured by obtaining the Gardeners' Chronicle Special Binding Case, one for each half-year. The numbers can, if desired, be kept permanently in the binder, or they can be kept in it until the set is complete, and then bound in the ordinary way. In either case, the advantage of keeping the copies clean and whole is obvious to every book-lover

Index Londinensis. THE long hoped for and long expected revision of "Pritzel"—*Iconum Botanicarum Index Londinensis*—has appeared, and its appearance will be received with pleasure and gratitude by botanists and horticulturists throughout the whole world. The pleasure is derived from the fact that here—when the work is completed—will be a splendid index to plant illustrations that have appeared in botanical and horticultural publications from the time that Dr. G. A. Pritzel published his *Iconum Botanicarum Index Locupletissimus*, in 1855, down to the end of 1920. More than a score of years have elapsed since Sir David Prain, then Director of the Royal Gardens, Kew, together with the Council of the Royal Horticultural Society, urged the necessity of a revision of Pritzel's work. To their appeal, however, there was no response, but in 1912 a sum of £250 from the profits of the great International Horticultural Exhibition, held at Chelsea that year, was set aside as the nucleus of a fund for carrying out the much needed revision. The Council of the Royal Horticultural Society decided to take action in the matter, but the war period intervened, and it was not until 1917 that Committees were formed to draw up recommendations for the conduct of the work. Eventually, the Royal Horticultural Society very generously agreed to provide the funds, and the Kew authorities to carry out the work. Dr. O. Stapf was appointed Honorary Editor, and the Director of Kew placed a room and the resources of Kew at the disposal of the *Index* staff. By the summer of 1927 the work was so well advanced that it was possible to issue a prospectus and proof page. Negotiations were conducted with the Delegates of the Clarendon Press, at Oxford, for printing the work, and in 1928 the card index of the first volume was placed in the hands of the printers. This volume, from Aa to Campanopsis, contains 84,000 entries, and it is estimated that the complete work of five volumes will contain no fewer than half-a-million entries. The enormous amount of work entailed may be gathered from the statement that the *Index* contains 107,000 references from Pritzel's original work and supplement, and about 380,000 additional references—including many omitted by Pritzel—from the "vast pictorial literature published since 1865." These references are confined to Phanerogams and Ferns and Fern allies, and represent portraits of plants, or of parts of plants, or the habit of plants (as a tree), but not anatomical details. Further, no distinction has been made in their admission between illustrations of species, sub-species, varieties or hybrids, so long as these are accompanied on the plate, or in the text, by a scientific (Latin) name, and, in the case of hybrids, so long as the name conforms to the designation of a species or a variety; but figures with merely generic names are excluded. An effort has been made to unify the spelling of plant names, as these are frequently at variance; authors' names are quoted throughout. In many instances cross references are cited, but, of course, it has not been possible to verify the naming of the plants illustrated. "Names are given as they occur, and the student is left to examine and appraise their correctness." The Preface is printed in English and in Latin; the Introduction in English only; and the Key to the Use of the Index in English, French and German. These are followed by a list of subscribers. Volume I consists of 547 pages, each ten inches by twelve-and-a-half inches, and the type and printing are of that excellence expected of the Clarendon Press, who are the publishers. The price is £5 5s. od. per volume. The work of compiling such an Index is exacting, as checking and cross-checking are necessary to secure accuracy. Moreover, card indexing is not an exhilarating business. It is a pleasure, therefore, to find Dr. Stapf not only expressing his indebtedness to the courtesy and painstaking assistance which he has received on all sides, but also paying a tribute to the "devotion with which the members of the staff, during these many years, have applied themselves to the task, often a monotonous and an irksome one. Without their hearty collaboration the work could not have advanced as it did, nor could it have attained the degree of completeness it may claim." We offer our hearty congratulations to the Editor, to the authorities at Kew, to the Clarendon Press, and last, but by no means least, to the Council of the Royal Horticultural Society, for the public spirit and enterprise shown in making the revised "Pritzel" possible. Our appreciation is sincere as the new work will be a material and frequent help to us. When looking over the first two-hundred-and-fifty pages of the work we found one-hundred-and-forty-four containing references to illustrations that have appeared in *The Gardeners' Chronicle*, but as there are several references on some of these pages we believe the average would work out at nearly one per page. Whether this is so or not, we are justifiably proud of our own record as revealed in the pages of the first volume of *Index Londinensis.*

Our Supplement Plate.—The illustration given as a Supplement Plate accompanying the present issue, shows one of several sets of herbaceous borders in Mr. S. Wallrock's garden, at Manor House, Stanmore, Middlesex, where gardening is carried out with great skill and enterprise. The borders illustrated are on the higher ground, and below them runs a long terrace-walk with arched iron-work that carries numerous Roses and other climbers; by a cunning arrangement of electric lights, this creeper-covered walk and the herbaceous borders may be lighted at night for the entertainment and education of visitors. The borders are well designed, and the soil has been worked and fertilised to a great depth for the purpose of producing first-class results, notwithstanding the close planting that has been practised. They contain a fine selection of hardy border plants, and when we saw them nothing was finer than the two forms of Anthemis tinctoria— Kelwayi and C. E. Buxton—indeed, we have never seen these subjects grown so well or flowering so abundantly as at the Manor House. From the stone-paved path between the borders, a fine view is obtained of the village of Stanmore, with its red-roofed houses nestling amid the green foliage of tall trees.

Proposed International Fixed Calendar.—The question of a revised and fixed calendar has cropped up on many occasions, but our American friends have made some progress in regard to it, inasmuch as the National Committee on Calendar Simplification has reported to the U.S.A. Secretary of State and urged the holding of an International Conference on Calendar Reform. The Committee recommends that an international fixed calendar should contain thirteen equal months of twenty-eight days each, the first day of each month being a Sunday; that a new month be placed between June and July; that the three-hundred-and-sixty-fifth day be an extra holiday, following December 28; that the extra day necessitated by Leap Year be a holiday, to follow June 28; and that all holidays, regardless of where anniversary dates fall in a week, be observed on a Monday.

Deeside Field Club Outing.—With the month of October came the last of the excursions held under the auspices of this Club during 1929. It proved a memorable day, the attendance numbering over two hundred—a wonderful record for an October meeting—and the outstanding feature was the recognition of the excellent services rendered to the Club by the Hon. Secretary, Mr. J. B. Philip. The tour embraced the Blue Hill, Elsick House, and Muchalls Castle, all in Kincardineshire. Miss Mabel Stewart, daughter of the late Sir David Stewart, described to the party the exquisite stretch of country to be seen from the Blue Hill, an eminence on the Stewart estate of Banchory-Devenick. And right well did Miss Stewart fulfil her task, her fine knowledge of a district in which she was born and reared standing her in good stead. Onward again went the long cavalcade of 'buses to Elsick House, the home of Lord Carnegie and his wife, Princess Maud, younger daughter of the Princess Royal. Lord Carnegie awaited the large company on the lawn, and offered them a very warm welcome. Elsick House could not accommodate so large a muster, and the meeting was held under the shadows of the fine trees found here. Mr. Charles Davidson, Convener of the Excursions Committee, congratulated Lord Carnegie and Princess Maud on the birth of a son and heir, who, if spared and well, should one day become the Earl of Southesk. Mr. G. M. Fraser, Public Librarian of the City of Aberdeen, then delivered an enlightening address on the Bannermans of Elsick, the progenitors of the Countess of Southesk, and gave many incidents in their wonderful careers down through the centuries. After an interchange of compliments and thanks to Lord Carnegie for his kindly welcome, the party proceeded to Muchalls Castle, where all arrangements for the visit to this early seventeenth century building was made by the proprietor, Dr. Macintosh. The Marquis of Aberdeen and Temair, accompanied by a large party from the House of Cromar, now arrived and took charge of the proceedings. Mr. Douglas Simpson, a leading authority on the ancient castles of Scotland, delivered a most interesting address on Muchalls Castle. On the motion of Lord Aberdeen, warm thanks were voted for all the facilities afforded the Club members that day. At this stage torrential rain fell, but, fortunately, the out-of-door business was completed. The party adjourned to Cookney Hall, a spacious and comfortable building, where the entertainment and good things provided were such that the weather outside was completely forgotten. The feast over, Lord Aberdeen proceeded to address the company, reminding them that the chief reason for their being there that day was to show their sincere appreciation of Mr. Philip's great services to the Club, both as Editor of the *Deeside Field*—unrivalled among all field club productions—and as the Honorary Secretary of the Club. Seldom had such a galaxy of talent appeared in the pages of a Club magazine, and so, as a slight memento of their affection and esteem for Mr. Philip, he had the pleasure of presenting him with a gold watch and chain, the former inscribed thus:—"Deeside Field Club.—Presented to J. B. Philip, Esq., M.A., with best wishes and thanks for the great services he has rendered the Club since its inception. October, 1929." Mr. Charles Davidson added his tribute to the good qualities of Mr. Philip, remarking that the Deeside Field Club had re-made Mr. Philip. It had brought him out of his "buckie," making the real man appear free from scholastic fetters, genial, witty, humorous. Mr. Philip, who spoke under deep emotion, warmly thanked the members for their gifts that day. He recalled happy memories of their tramps over mountains, woods and streams, and said the gifts would take a worthy place among his most cherished possessions. Following the presentation, Mr. Hugh F. Campbell, LL.B., gave a most interesting address on the origin of the place names visited by the Club that day. His fine record as a Gaelic scholar made Mr. Campbell's remarks fascinating in the extreme, and those who heard him came away wiser and better instructed members. A long and interesting day was made still more enjoyable by the new routes and scenes the party drove through on their return to Aberdeen.

Public Chrysanthemum Exhibitions in London.—The annual Chrysanthemum shows at Southwark Park, Waterlow Park and Finsbury Park, are now open; and those at Battersea Park and Victoria Park will commence on Saturday, October 19.

Leeds Paxton Society.—This long-established Society has arranged an excellent syllabus of lectures and exhibitions for the 1929-30 season. The meetings commenced on October 5 with an open exhibition night, and on October 12, Mr. F. Hawkins Leeds University, lectured on "My Garden in the Tropics." Other lectures to be given are "Formal Design in the Garden," by Mr. J. Addison, of the College of Art, Leeds, on November 9; "Perpetual Carnations," by Mr. F. Stabler, Cookridge Hall Gardens, on March 3, 1930; and "Leaves," by Mr. H. B. Osborne, Burley, on March 22. Evening exhibitions of various kinds will be held on November 23 and 30; December 14 and 21, 1929; January 4 and 18; February 8, 15 and 22; and March 15, 1930. The Chrysanthemum Show takes place on November 16; there will be a discussion on "The Season's Failures," on December 28, the Annual Meeting will be held on January 11 next, and the Annual Dinner on January 25. The Secretary is Mr. F. Goodhind, 194, Harehills Avenue, Leeds.

The National Park Committee.—The Committee recently appointed by the Prime Minister to enquire into the question of establishing a National Park, or National Parks, in Great Britain (see *Gard. Chron.*, October 5, p. 258), held its first meeting on October 10, when the preliminary questions of aims, procedure, and methods were discussed. The Committee hopes to secure the views of Lord Bledisloe on the subject at an early date, and then to consult the various societies interested in the diverse objects embraced by its terms of reference. The taking of evidence from private individuals is necessarily postponed for the present.

Mr. William Smith.—Since 1920, Mr. W. Smith has been gardener at Dunecht House, Dunecht, Aberdeen, first serving the late Lord Cowdray and now Annie Viscountess Cowdray. In recent years, Mr. Smith's name has come prominently before the horticultural world as a first-rate cultivator and successful exhibitor of Sweet Peas, Roses and fruits; indeed, he has beaten growers who seemed to have secured the freehold of certain positions in the prize lists of many northern shows. Mr. W. Smith served an apprenticeship under Mr. J. Sutherland at Craigiehall House, Cramond, Midlothian, and remained there for three years. Subsequently he gained experience as journeyman in the gardens at Blairdrummond, at Alloa House, at Shane's Castle, Co. Antrim, at Hopetoun House, and at Moulton Paddocks. Later he served as foreman at Foggyley, Dundee, and at Dupplin Castle, Perth, becoming gardener to the Rt. Hon. Lord Sempill, at Fintray House, Aberdeenshire, in 1910; this position he held for about ten years, before taking charge of the gardens at Dunecht House. Here he has cleared the garden of old bush Apple and other fruit trees and superintended the erection of a large range of glasshouses, wherein, in addition to Grapes and Peaches, he cultivates no fewer than seven hundred pot fruit trees under orchard-house conditions. He has also modelled a Rose Garden and planted it with four thousand Roses. In 1923, he was given charge of the policies which extend to six hundred acres, including a golf course and eleven miles of carriage drives. As a side line, Mr. Smith has laid out over thirty gardens attached to cottages on the Dunecht estate. He is especially proud of the Royal Horticultural Society's Silver-gilt Medal awarded to his stove and greenhouse plants in 1924; the Veitch Memorial Medal, for fruit, in the same year; the Royal Horticultural Society's Silver Medal for indoor plants in 1925, and the Dunn Memorial Medal for Apples in 1925, at Edinburgh.

MR. WILLIAM SMITH.

Passion Fruit Cultivation in New South Wales.—Writing in the *Agricultural Gazette* of New South Wales, Mr. W. H. Eastwood states "It is being asserted in some quarters that a yield of two hundred bushel cases of Passion Fruit per acre is a fair average yield under North Coast conditions. This estimate is greatly exaggerated and is, no doubt, based on the fact that some five years ago yields of that quantity were obtained in the Tweed River valley. It is most unreasonable, however, to assume that what can be achieved in that particular district is also possible anywhere on the North Coast, from Kempsey to the Tweed Heads. Moreover, in recent years, brown spot and woodiness have substantially reduced yields, and the grower, who, to-day, is harvesting one-hundred-and-forty bushel cases per acre should be satisfied that he is obtaining a fair average crop. Even to obtain that quantity, he will need to have a fair knowledge of proper cultural practices and disease control measures, and, in addition, be favoured with a normal season."

Linnean Society's Meetings, 1929-1930.—The dates on which Fellows of the Linnean Society of London will meet during the coming winter session, are November 7 and 21, and December 5 and 19, 1929; and January 9 and 23; February 6 and 20; March 6 and 20; April 3; and May 1 and 15, 1930.

Scottish Potato Crops.—The Department of Agriculture for Scotland has issued a statement showing the estimated acreage under each variety of Potato in Scotland in 1929, with the corresponding figures for 1928. In the first group, consisting of first-early varieties, the total acreage is given at 15,144, compared with 15,059, of which area Epicure accounts for a half, with 7,939 acres against 8,128. Duke of York, Sharpe's Express and Eclipse came next in the order given, and are the only other varieties running into a four figure acreage. The area under second-early crops increased from 19,413 acres to 20,550, due to the popularity of Great Scot, which was cultivated to the extent of 13,777 acres, compared with 12,287 in 1928. On the other hand, Ally only occupied 962 acres, or a decline of 580 acres. Kerr's Pink, with 47,329 acres to its credit, was the outstanding variety in the maincrop section, which had a total of 91,278 acres, or 1,145 acres less than in 1928. Arran Consul, Majestic, Golden Wonder and Arran Chief were not so largely cultivated, while King Edward showed an increase of 2,000 acres. The total acreage under Potatos was 145,000 acres, as against 144,026 acres last year.

British Gladiolus Society.—The Annual General Meeting of this Society will be held at the R.H.S. new Hall, Greycoat Street, Westminster, London, S.W.1, on Wednesday, October 23, at 3 p.m.

"Hardy and Half-hardy Plants."—The October issue (No. 6, Vol. I) of *Hardy and Half-hardy Plants*, a monthly journal edited and published by Mr. A. W. Darnell, 5, Lansdowne Terrace, Hampton Wick, Middlesex, contains illustrations, accompanied by brief notes, of Alströmeria chilensis (coloured), Trillium nivale, Gentiana bellidifolia, Tsuga Mertensiana, showing a cone-bearing branch; Lobelia ramosa, Calochortus amabilis and C. Kennedyi, the yellow-flowered Forget-me-not from New Zealand, Myosotis concinna, by no means an easy plant to grow successfully in this country; the seasonable Ceratostigma plumbaginoides (syn. Plumbago Larpentae), Corydalis ochroleuca, the Southern Goat Orchis, Orchis longibracteata (syn. Barlia longibracteata and Loroglossum longibracteatum); Soldanella pusilla, Campanula Allionii, Saxifraga lilacina, Disporum Smithii, the Flowering Rush, Butomus umbellatus, Kniphofia rufa, Calceolaria mexicana, Styrax officinale, the beautiful Gentiana Kurroo, and Lomaria alpina, the New Zealand Hard Fern.

The Lord Mayor's Dinner to the Fruiterers' Company.—The Lord Mayor and Lady Mayoress gave a dinner at the Mansion House last week to meet the Master, Wardens and Court of the Fruiterers' Company, and the chairman and members of the General Purposes Committee of the City Corporation. In accordance with ancient custom, the annual presentation of home-grown fruits to the Lord Mayor was made by the Fruiterers' Company, and a splendid display of fruits was arranged in the banqueting hall. The origin of this custom of presenting fruits to the Lord Mayor is traceable to the fact that the Lord Mayor's "meter" was formerly entitled to a sample from every load of fruits which came into the City, but as the practice led to considerable controversy it was arranged that a present of fruits should be made by the Fruiterers' Company to the Lord Mayor annually, and in return the Lord Mayor would entertain the Court of the Company at a banquet. The Lady Mayoress was presented with a case of silver spoons on behalf of the Fruiterers' Company. The gift of fruits was distributed to charities.

Potato Breeding in Scotland.—At the Conference which followed the demonstration of seedling Potatos at Messrs. McGill and Smith's trial grounds at Ayr, on Monday, October 7, the question whether the intensive breeding and testing of new varieties has been of practical value to growers, was discussed at length by the experts who were present. The subject was introduced by Mr. William Robb, of the Scottish Plant Breeding Station, who quoted official statistics which led him to the conclusion that Potato breeding should be encouraged by every means. To discourage it meant abandoning enterprise, which was as much needed to-day as ever it had been in the past. Mr. W. D. Clark, Berwick, advocated a reduction in the number of varieties. Good varieties should be chosen and their quality improved by selection. He held that Epicure's great success in Ayrshire was due to the fact that it was the only variety grown there. Mr. Millar, of the Department of Agriculture, described the work being done at the Plant Registration Station in the testing of seedlings, and said they hoped to be able to indicate to the public within a short time what varieties were really worth taking up. Mr. O'Brien did not deprecate the value of selection, but Potato varieties had a comparatively short lifetime, and something must be done to put new varieties on the market to take the place of those which lost favour. Mr. John Gibb, Bishopton, a member of the Synonym Committee, declared that it would be a suicidal policy to reduce the number of varieties as they must cater for the English market, which was quite different from the home market. There were many interests concerned with Potatos, but the housewife's ideal was the deciding one in the end. While the much lauded Epicure made a few Ayrshire farmers rich, it made the rest of the farmers in Scotland poor! He declared that Epicure was a Potato of bad quality, forced on the public by the Ayrshire farmers. Mr. John Watson, the firm's expert at Alloway, doubted if any of the new varieties except Kerr's Pink and Great Scot had put much money into the farmers' pockets. Speaking on behalf of the firm, the Chairman, Mr. Hugh Smith, observed that they had not seen much direct return from Potato breeding, and Mr. Robb, in replying, said selection could only maintain the quality and productiveness of a variety, and not improve it. The company, by a unanimous verdict, answered the original question in the affirmative.

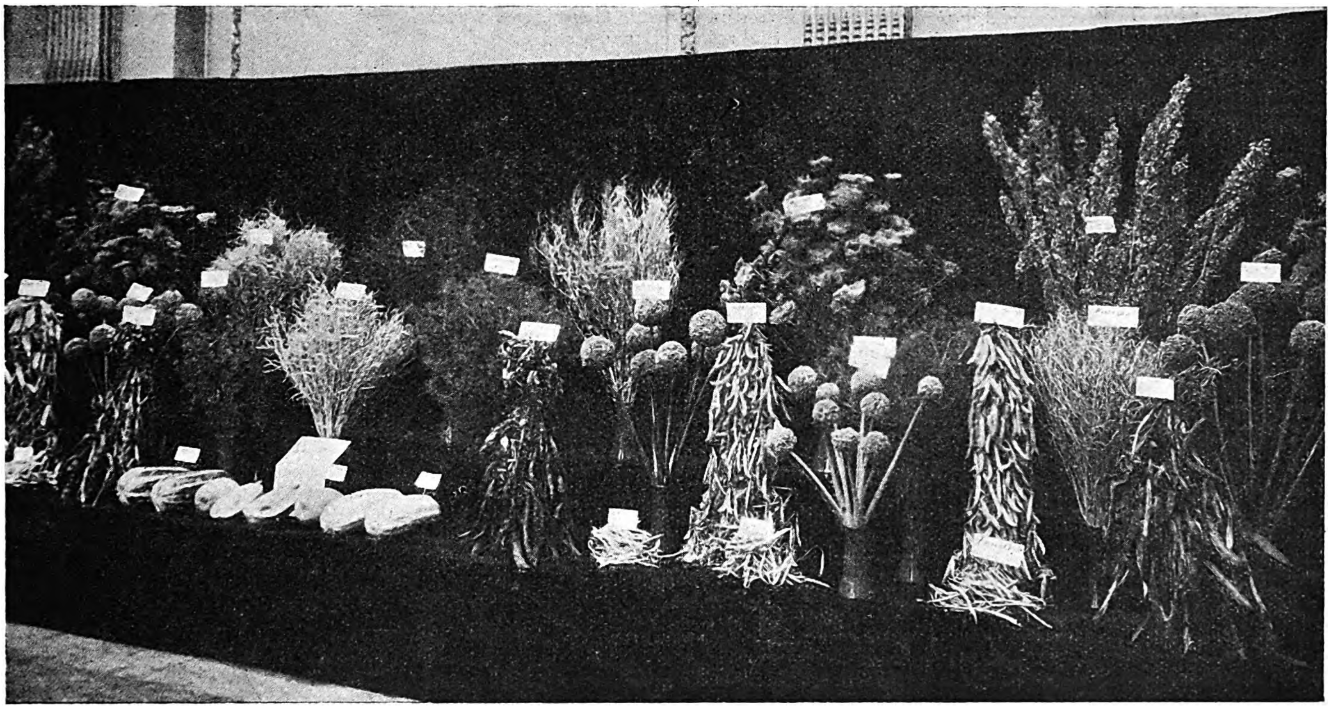

FIG. 143.—EXHIBIT OF VEGETABLE SEEDS BY MESSRS. DOBBIE AND CO., LTD., AT THE R.H.S. FRUIT AND VEGETABLE SHOW. (see p. 314).

Mr. J. F. McLeod.—As intimated in our issue of October 12 (p. 293), Mr. J. F. McLeod, formerly of Dover House Gardens, Roehampton, has returned to Scotland after forty years' residence in England. After retiring from Dover House, where he served the Pierpont Morgan family for very many years, he took up farming in Essex, and more recently he has resided at Ware. For family reasons, Mr. McLeod and his family have now returned to Scotland and taken up residence at Leven House, Milnathost, Kinross, where he has a large garden set in a beautiful and not too thickly wooded district. For about thirty-five years Mr. McLeod has served on the Royal Horticultural Society's Floral Committee, and for a considerable period has been a Vice-Chairman of Section A of that body; he has also been a member of the joint Dahlia Committee, and a prominent member of the governing body of the Royal Gardeners' Orphan Fund. His removal to the north has compelled him reluctantly to resign these positions, and his many friends in the south deeply regret this severance of so many long associations. At the same time, they wish Mr., Mrs. and Miss McLeod good health, new friends, and all possible happiness at Milnathost.

R.H.S. Lindley Library.—It is announced by the Royal Horticultural Society that owing to the reconstruction of the Society's offices and the Lindley Library, the service of the Library will be interrupted. During the actual removal of the Library to its new rooms on the third floor of the present building, which will take place between the months of February and April, 1930, reading accommodation will not be available; it is hoped, however, to maintain the loan system throughout the period of reconstruction, although delays may occur in satisfying Fellows' requirements. Any further notice will be published in the 1930 issue of the *Book of Arrangements*.

Appointments for the Ensuing Week.—Monday, October 21: National Chrysanthemum Society's Executive and Floral Committees meet; Harrogate and District Horticultural Association's meeting. Wednesday, October 23: Royal Horticultural Society's Autumn Show (two days); Newcastle and District Horticultural Society's meeting; Wimbledon Gardeners' Society's meeting. Thursday, October 24: Holland County Potato Show. Friday, October 25: Imperial Fruit Show, Birmingham (nine days). Saturday, October 26: Leeds Paxton Society's Social Evening.

"Gardeners' Chronicle" Seventy-five Years Ago.—*New Plants: Whitlavia grandiflora. Harvey in the London Journal of Botany, Vol. v. t. II. Bot. Mag., t.* 2,813.—A specimen of this fine plant was exhibited last summer at Chiswick by Messrs. Veitch, and it is certainly the gem of the season in the class of hardy annuals. It will no doubt be as hardy as a Phacelia or Eutoca, the latter of which it resembles in its foliage, but then its brilliant blue flowers are as large as those of a Campanula and much finer than anything else of the kind. Mr. W. Lobb found it in California on the mountains of St. Barbardino; but it was originally discovered in that country by the late Dr. Coulter. Dr. Harvey, who first described the plant, naming it after Francis Whitla, Esq., distinguished two supposed species, *grandiflora* and *minor*; but we entertain no doubt that they are, we do not say varieties, but states of the same plant. We had both of them in flower on our table from Messrs. Veitch at the same time. The fact seems to be that the plant when in great health is *grandiflora*, and when weak, from a shady place, is *minor*. Dr. Harvey thought they might differ in the form of the scales which stand at the base of the stamens; but we found those scales varying in form from being acutely bifid to being entire and wedge-shaped with the angles rounded off. *Gard. Chron., October* 21, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Seedling Orchids. — When the interesting business of raising and growing seedling Orchids is practised there are generally some plants which require attention throughout the year. Either fresh batches of seedlings require removal from the seed-beds into other receptacles, or older plants need potting on into larger pots, the chief object being to grow them on to the flowering stage so soon as possible; therefore, they should receive every encouragement for rapid, yet sturdy development. At the present time, seedlings of some of the warm-house kinds are completing the growth of the first leaf, and these require transferring singly to very small pots, or, if room is limited, several may be placed in store pots of two-and-a-half inch size to allow them to become established before the short winter days arrive, when the growth will not be so fast, and less moisture, both in the atmosphere and at the roots, will be needed, although seedling Orchids should never be allowed to remain dry for long periods, nor any attempt made to rest them before the flowering stage is reached.

Cattleya Seedlings.—Where seeds from this large group of Orchids were sown earlier in the year and germinated successfully, many of the larger seedlings should now be ready for transferring singly into small pots or several together into store pots, and kept in a warm and moist position. They will quickly establish themselves at the warmer end of the house. Larger seedlings that have matured their pseudo-bulbs are now producing new roots from the base of the growths, therefore these should be repotted into slightly larger receptacles before they become pot-bound. Use well-drained pots and a compost of A.1. and Osmunda fibre, and Sphagnum-moss in equal parts, the whole chopped up moderately fine, and pressed in firmly around the roots. Give sufficient water to moisten the compost through, and afterwards give just sufficient to keep it moist; avoid saturation as the roots will quickly decay under such conditions. As the shorter days approach, growth becomes very slow, consequently less water will be needed than during summer conditions, but no attempt should be made to rest the plants by withholding water until the flowering stage is reached. When a house is devoted to seedling Orchids of the warm-house kinds, their requirements are more easily maintained by keeping the house a few degrees warmer and the atmosphere more humid than in the house where the larger plants are grown. Should the seedlings have to be grown in the same house as the established plants, a warm corner should be chosen for them, where they can be placed in a position near the roof-glass and given more humid surroundings and shaded from strong rays of sunshine. Occasional fumigation with Xl All should keep thrips and other insect pests in check.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

The Propagation of Bush Fruits.—Cuttings of Gooseberries and Currants may now be inserted out-of-doors, and they should root quite readily if the soil is sufficiently gritty and the situation open to full light. The cuttings should be made from the current year's growth, selecting strong, well-ripened shoots from bushes that are known for their cropping and other good qualities. They should be inserted in trenches four to six inches deep, making the soil, particularly at the base, very firm about them. The cuttings should stand six inches apart and quite double that distance should be allowed between the rows. With Gooseberries and Red and White Currants, the cuttings should be about twelve inches in length after the immature tips have been cut away. The lower ends should be cut square immediately below a joint, and all the buds removed except the top three or four, which should eventually form the main branches and framework of the bush. In the case of Black Currants, however, cuttings six to eight inches in length are all that are necessary, and all the buds on these should be retained, the object being to encourage all the sucker, or basal growths possible, as it is on these strong growths that the finest fruits are obtained. It is advisable, in the case of Gooseberries, to remove all the basal buds, not only to eliminate the risk of sucker growths, which are a nuisance in after years, but because one of the worst diseases to which the Gooseberry is subject, viz., American Gooseberry mildew, invariably attacks these soft basal shoots, so the diseased area is increased, and the chance of the disease being carried over from season to season is all the greater. Gooseberry bushes on nine-inch stems do not make such soft growth, besides, the branches being well clear of the soil, there is less danger of the berries being splashed with grit during rain storms in the fruiting season. Cuttings inserted now, while there is yet a little warmth in the soil, callus over quickly, and roots are formed which are able to develop and sustain top growth next spring, which cannot be expected from cuttings made and inserted late in the winter.

Pruning Bush Fruits.—The pruning of established Gooseberries and Red and White Currants is a simple matter, and yet it should be done in an intelligent manner if the best results are to be obtained. There should be an annual cutting out of old and worn-out branches, and those that tend to hang too low, and a removal of all sucker growths from the centres. The branches that remain should be disposed thinly, so that the hand may pass freely between them, to admit light and air, and to facilitate the gathering of the fruits. All the lateral shoots on these main branches should be spurred back to within an inch or so of their origin, reserving any well-situated shoots on these branches, where there is room, to take the place of some of the older ones. Leading shoots, and others, on main branches may be allowed to extend from six to nine inches, according to the amount of room to spare. In that way the vigour and health of the bushes may be maintained. The pruning of established Black Currants is exactly opposite to that of the foregoing. The finest fruits are borne on the shoots of the previous year. Pruning should be confined to cutting out superfluous and badly placed growths, encouraging so much new growth as possible, capable of bearing the best fruits, but overcrowding should be avoided in every case.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Gloxinias.—Plants that were raised from seeds sown last spring and which have passed out of bloom should be dried off gradually, and so soon as the foliage is ripe they may be laid on their sides in a moderately warm place. Young Gloxinias need very careful ripening, otherwise a large percentage of the small tubers may be lost during the winter. It is not wise to dry them off so severely as the older plants.

Bulbs.—Continue to pot bulbs. Early Tulips may be grown in much smaller receptacles than are required for the Darwin type, which may be grown in seven-inch pots, but both of these groups of Tulips may be grown in boxes and transferred later to large bowls for the decoration of the dwelling-house. Where quantities of cut flowers are in demand, the bulbs are best grown in boxes, but care should be exercised against overcrowding. Darwin Tulips will not submit to the same amount of forcing as other Tulips, but they may be grown successfully under glass by allowing them to develop slowly. In my opinion, the Darwin Tulip is one of the most useful subjects for supplying blooms with long stems in the early spring, especially as varieties in many shades of colour are now available. Narcissi of various types may be treated in the same manner as these Tulips if a quantity of bloom is needed for cutting.

Begonias. — Autumn- and winter-flowering Begonias are now growing freely and the main shoots of varieties of the Optima type, such as Eclipse, Ideal, Exquisite, and many others, may need the support of neat sticks to prevent them bending over through the weight of their flowers. These Begonias will provide a display over a long season, if some of the early-raised plants are allowed to develop all their flowers after this date, and those that were propagated later in the season have their buds removed once more before allowing them to bloom. Encourage the later plants to make healthy growth by giving them weak liquid manure alternately with clear water. Unfortunately, these Begonias dislike fogs, therefore all ventilators should be kept closed and the atmosphere allowed to become as dry as possible on such occasions. Fumigate the late plants after the removal of the flower buds so as to keep aphis and Begonia mite in check.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Peaches.—The season has been most favourable to the ripening of the wood of Peach trees, and no further time should be lost in bringing all root-lifting, root-pruning and renovating operations to a close. Often many of the best roots are destroyed when root-pruning unless great care is exercised. All the strongest roots should be shortened to within a few inches of the surface of the undisturbed ball of soil, which may be three feet or even six feet in diameter, according to the size of the tree. All the more fibrous roots—the real workers—should be kept moist and carefully retained. If the compost is good, this can be returned in thin layers and made very firm, spreading out the retained roots as the work proceeds, after which the whole mass should be watered well. In some instances it may be necessary to repeat this operation the following year, as where large, healthy trees break into strong growth, they advance rapidly to grossness, making growth which seldom produces fruits the following year, no matter how favourable the autumn may be for ripening the wood. Trees which have been checked by root-pruning are most likely to set a good crop of fruits, while the fresh roots will make full use of the mulching and feeding when the crop needs it. Any trees prepared last autumn in the open may now be brought inside to fill vacancies in the borders. A very important preliminary operation is that of giving these trees one or two good waterings before lifting is attempted. If, after being placed in position and tied loosely to allow for settling, a little light shade is given for a few days, and the house is kept rather close and the trees syringed frequently, large trees should re-establish themselves within a month, but on such trees all shoots should be left intact until the young fruits are set and swelling. Pruning of Peach trees may now be carried out, but if former directions have been attended to, only the removal of a shoot here and there will be necessary. All trees should be detached from the trellis and carefully washed with Gishurst compound or strong soapy water, and the woodwork of the house should also be cleansed. If the trees have been free from insect pests, one washing should suffice, but if scale is present two washings, properly performed, should prove more satisfactory than painting with clay, etc. Late trees, now clear of fruits, should be kept clean with the hose. Their roots should be kept thoroughly moist until the leaves fall. The wood of these trees should be thinned carefully to let in plenty of light and air, and any root-pruning should be finished before the end of October.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Deciduous Shrubs.—Cuttings of many of the hardier and commoner deciduous shrubs may be rooted under similar conditions to that advised for Roses; this is a useful plan to adopt in private gardens, so that young, vigorous plants are always at hand to replenish worn-out subjects. Select growths that are well ripened and of medium length for this purpose, avoiding the strong, succulent shoots, and remove them with a heel of the old wood attached. The securing of a heel is an important factor in the success or failure of rooting cuttings under these conditions.

Pinks.—If pipings of these were inserted they should now be rooted sufficiently to be planted in their permanent quarters. These, like border Carnations, repay generous treatment; therefore prepare the site they are to occupy by trenching two feet deep and working in a supply of good, rotted manure as the work proceeds; the benefit of deep working and generous treatment of the soil is amply demonstrated during dry seasons, such as we have experienced this year.

Climbers and Shrubs on Walls.—With the approach of stormy weather, all climbers and shrubs on walls should be made secure to prevent damage by autumn gales. The method universally adopted is to tie them to wires that have been secured to the walls; when doing so it is usual to use a strong, coarse string, such as tarred twine. This is very often tied much too tightly, leaving the growth little or no room to swell, and eventually cuts into the bark, with the result that the branch is ultimately destroyed, and affords evidence of bad workmanship. Examine all previous ties and renew those that are decayed or likely to cause damage.

Specimen Plants in Tubs.—Plants of a half-hardy nature, in tubs, should now be removed to a place where they may be protected during severe frosts. A cool greenhouse, with a command of artificial heat, is best, but some of the hardiest subjects, such as the well-known Agapanthus, may be stored in a frost-proof shed, provided there is sufficient light. Specimens of deciduous plants, such as Fuchsias and Pomegranates, are happy if stored during winter in a warm shed or cellar, even if nearly all the light is excluded. They require very little water during the resting period, but should not be allowed to become dust dry. Those of an evergreen character require light, and attention to watering once every two or three weeks.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Leeks.—The hoe should be kept going between any late-planted Leeks, and they may be given a dressing of artificial manure to encourage their growth. It is advisable to draw the soil up around the plants to secure a good length of blanched stem, and also to afford a certain amount of protection from frosts during the winter.

Salads.—Make further sowings of Mustard and Cress, also Onions in boxes, for salad purposes. Lettuces may still be sown in a sheltered, warm border; black-seeded varieties should be chosen for this purpose on account of their hardiness.

Celery.—Late-planted Celery plants should now receive their final earthing up. See that plenty of soil is worked around the stalks and made fairly firm, and dust soot around the plants to keep slugs in check.

Cabbage.—The final planting of spring Cabbages should be made now, so as to allow the plants to secure a good root-hold before the cold weather sets in. If plenty of frames are available, a few of them may be filled with early Cabbages, which should be ready for cutting a few weeks in advance of the out-door plants.

Globe Artichokes.—As the leaves of these are now dying off, the plants should be cut back and the bed lightly forked, after which it should be covered with a light mulch of farmyard manure to protect the crowns during the winter; ashes or rough leaves are also suitable for this purpose.

General Work.—As crops are cleared, the vacant ground should be dug and the surface left so rough as possible to allow of the beneficial effects of weathering. Heavy clay soil should have plenty of rough ashes and a quantity of lime-rubble worked into it, and should then be ridged. Bastard trenching is the most suitable method of dealing with the ground, as when done properly no soil is left unturned, and it allows vegetable refuse and other material to be worked into the ground to a good depth.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemount, Monkton, Ayrshire.

Spring Bedding.—Most of the summer bedding plants have passed their best, even if frost has not altogether finished them, and steps should be taken to get Wallflowers and other spring flowers planted at once, so that they may have a chance of becoming well established before growth ceases. Endeavour should be made to change the scheme of planting from one year to another, as great variety is possible in spring-bedding schemes. Wallflowers may be planted in separate beds of different colours, or they may be associated with Tulips. Myosotis Royal Blue harmonises with various Tulips, and Arabis albida makes a good groundwork for Tulips and other spring-flowering subjects. The Siberian Wallflower, Cheiranthus Allionii, is also very effective, either alone or in combination with bulbs. In preparing the ground it should not be necessary to add fresh manure now if a supply was given in spring. Make the soil reasonably fine by working it well, and get the plants into position, introducing the bulbs afterwards. Where the soil is heavy, dry days should be chosen for the work, and if bulbs of any kind are planted, a little rough sand should be placed beneath them so as to prevent excessive moisture collecting around them during the winter and thus cause decay.

Violets.—Remove any decayed leaves which appear, and keep the surface of the beds constantly stirred. Give water, if necessary, and keep the lights off on all favourable occasions, as Violets in frames should be grown so hardy as possible.

The Carrot Bed.—To grow good Carrots it is necessary that the soil be deeply worked, and the earlier in the autumn this is done, the better. If there is a good depth of soil, trench the ground; if not, double-dig it, for no matter how poor the subsoil may be, it is better broken up, and any decaying vegetable matter available added to it. It is not wise to incorporate fresh manure in the soil for this crop, but an annual coating of leaves or leaf-mould should prove beneficial. It is a good plan in many cases to grow Carrots on the same ground for several years. Peat, in quantity, may also be added to the soil with advantage, and if Carrot fly gave trouble during the past season, give a dressing of a good soil fumigant. Soot may be applied now, but it is better given at seed-sowing time.

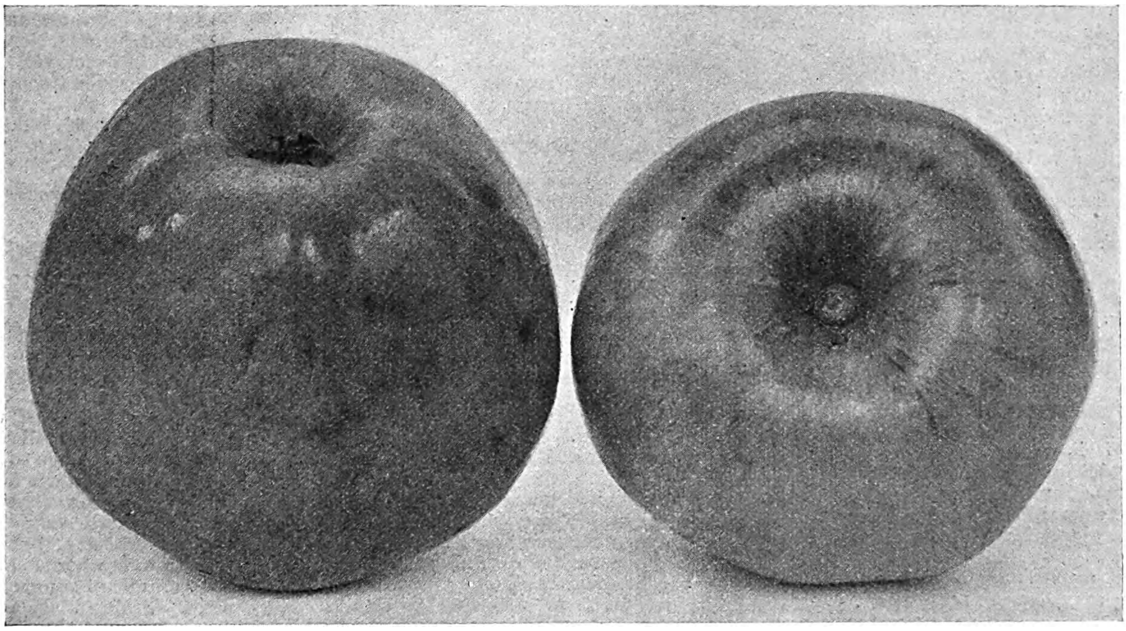

FIG. 144.—APPLE HOWGATE WONDER.
R.H.S. Award of Merit, October 8. Fruits large, yellowish-green, flushed with red.
Shown by Mr. G. Wrathen, Bembridge. (see p. 293).

TREES AND SHRUBS.

KOLKWITZIA AMABILIS.

ALTHOUGH this shrub has thriven with remarkable vigour and appears in other respects to be thoroughly satisfied with the good loamy soil and open position in which it has been established for several years, it has not yet produced a single blossom. It is a species of so much distinction and charm, according to Mr. W. J. Bean and other authorities, that its refusal to blossom is the more disappointing. Yet one hesitates to do away with such a shrub until every hope of discovering its unsatisfied demands has been abandoned.

K. amabilis was found by Mr. E. H. Wilson in Hupeh at an elevation of 9,000 to 10,000 feet, and it is recorded that it first flowered in this country at Coombe Wood, in 1910. If I am correct in stating that it was discovered growing among rocks, it may be that poverty of soil, with some root restriction, may induce it to bloom. Anyhow, it would be interesting as well as helpful to know whether any reader has tried such treatment and, if so, with what results. That the shrub is absolutely hardy, there seems no doubt. Its foliage and the natural elegance of the slender growths are in every way delightful. The one thing wanting is the bell-shaped, Abelia-like flowers, and I should be more reluctant to write of my own failure to induce the shrub to yield these had I not been aware that some gardeners of greater experience and more extensive scope are equally unsuccessful. *J.*

SOPHORA JAPONICA.

SEVERAL representatives of the Japanese Pagoda Tree, Sophora japonica, flowered freely on the lawns at Kew. With their dark green, pinnate leaves, and quantities of creamy-white flowers, they form most attractive and interesting large specimen trees.

The specific name suggests that the tree is a native of Japan. The generally accepted conclusion now is that it is one of the numerous trees and shrubs which are natives of China, but have been cultivated in Japan for hundreds of years, and were introduced to British gardens from Japan. Sophora japonica is also a native tree of Korea.

The date of its first introduction to British gardens is given as 1747. The oldest tree of Sophora japonica at Kew was planted in 1762, being one of the trees and shrubs removed from the Duke of Argyll's garden at Whitton, which formed the nucleus of the first arboretum established at Kew by Princess Frederick of Wales. The old tree is not so vigorous as formerly, the larger limbs being held together by steel bars, while several large holes are filled with cement. It is, however, an object of considerable interest to visitors, and an example of the tree-doctor's skill in prolonging the life of old veterans.

Cultivated as a specimen tree, Sophora japonica is of rounded, spreading habit with branches low down on the trunk. The height varies from about fifty to seventy or eighty feet, with a spread of branches almost or quite as wide. There is a tall specimen with a large, clean trunk at the south end of the Holly Walk, of upright habit, obviously the result of close planting.

Sophora japonica is one of the latest trees to develop its foliage in spring, and is also one of the last trees to shed its leaves late in the autumn. The attractive, deep green, pinnate leaves consist of from nine to fifteen leaflets. The small, creamy-white flowers are Pea-shaped, and produced freely in terminal panicles. *A. Osborn, Kew.*

LEUCOTHOE DAVISIAE.

THIS attractive species is one of the most delightful of all those once called Andromedas, and as a flowering shrub it is well worthy of being placed in the very front rank among its own and allied genera. L. Davisiae is an evergreen of about two feet in height. It spreads slowly by means of underground runners and, under suitable conditions, eventually makes a compact thicket of growths several feet across. The habit is upright and the rigid branches are amply furnished with ovate-oblong leaves, leathery in texture and of a rich, glossy green. These leaves may be so much as two inches long and half as wide, and they are slightly toothed at the margin. About midsummer, flowers appear in clusters of erect racemes which rise from the terminal leaf-axils and ends of the branches. Each of these racemes is some three or more inches long and the snow-white, pendulous, pitcher-shaped corollas are fully a quarter-of-an-inch in length. Not only does the pure whiteness of the blossoms look remarkably well against the rich green leafage, but the bunched racemes stand erect and quite clear of the foliage.

L. Davisiae, a native of the Californian Sierra Nevadas, was first discovered and introduced (1853) by William Lobb. Although generally classed as a peat shrub, it will prosper in any free, acid loam, which does not get too dry in summer. With me it grows and flowers in what one might call a good Heath soil, with light shade from deciduous trees. Under such conditions I have seen it doing well at Wisley. In spite of its Californian origin, L. Davisiae appears to be quite hardy, and the facts that it flowers late and does not expose its budded racemes to any risk of frost as do some of its allies, are much in its favour.

PHYLLODOCE COERULEA.

THOSE who grow Ericaceous shrubs should find this an interesting plant and one that is, in many places, difficult enough to impart a certain zest to its culture.

P. coerulea is a rare native, found only in one part of Scotland, but it has a wide range over the northern hemisphere, including both the Old and the New Worlds. Being a little shrub not only of the north, but of lofty altitudes, it does not take kindly to southern conditions, but once it is spared the trials of a parching sun and insufficient moisture it can be grown and flowered with much satisfaction. It is naturally a peat lover, but I have grown it for years in a light, lime-free loam which has a naturally cool subsoil, the root-run being rendered more retentive by the use of really old leaf-mould. Peat-moss that has been well weathered is also a useful absorbent both for mixing with the soil and for top-dressing. Full exposure to sun is desirable where uniform moisture is always sufficient in summer, otherwise the plant may be given the northerly side of a sheltering rock.

P. coerulea makes a twiggy, compact little shrub some six inches high, the branches being furnished with blunt, linear, evergreen leaves of a dark, glossy green. With me the plant almost invariably flowers twice a year, in June, or earlier, and again in September. The blossoms, which are borne either singly or in small umbels, are carried on erect, one-inch stalks, the drooping, pitcher-shaped corollas being fully one-third-of-an-inch long. The specific name implies that these blossoms are blue, but I have never yet seen one which is other than mauve, or bluish-purple. However, one can at least give the species credit for possessing the bluest flowers of its genus, most of the others being of some shade of rose or pink.

RHODODENDRON VASEYI.

IT is always pleasing to see an old plant brought into prominence and easily holding its own among novelties of the highest merit. That is how many must have felt when they saw R. Vaseyi occupying a position of prominence in that magnificent collection which the Bodnant Gardens staged at the last Chelsea Show. I had grown R. Vaseyi for a number of years and, therefore, felt guiltless of the charge that "so beautiful a shrub should so long have escaped notice" (W. J. Bean: *Trees and Shrubs Hardy in the British Isles*), but when I came to compare my own with the Bodnant specimens they were as water to wine. Their almost white blossoms, clustering the leafless branches of early May, were certainly not to be regarded as unworthy, even where space is a consideration, but the loveliness of that rose-pink of the others was nearly enough to induce me to believe that I had never grown this delightful species at all. These shrubs, with the flowers nearly pure white, were undoubtedly seed-raised, and the significance of the point will not pass unobserved by those who are planting the species this season.

R. Vaseyi is a deciduous North American species. Discovered in 1878 in North Carolina by Mr. G. R. Vasey, it was introduced some ten years later, but for some unknown reason it has never been accorded the notice it deserves. It is hardy, and its slender, open, rather upright habit and medium stature render it a very suitable subject for gardens of moderate area, and I know of no better shrub for grouping among dwarf Heaths or other Ericaceous plants either in the open or in thin woodland. It flowers regularly and abundantly; the flowers withstand our spring weather singularly well, and the linear-oval leaves, averaging about three inches in length, assume brilliant autumnal tints. The blossoms, one-and-a-half inch across, are borne in clusters at the tips of the twigs, and so firm are they in texture that the leafless shrub at a little distance might suggest a miniature Magnolia.

R. Vaseyi is the most distinct and, perhaps, the most beautiful of all North American deciduous species, and not the least of its many valuable attributes is its ease of culture in any average lime-free loam. I find it as good a drought resister as the old R. flavum, even on my hillside banks. *North Wales.*

WOODLAND GARDEN.

KITAIBELIA VITIFOLIA.

ALTHOUGH this herbaceous perennial may be unworthy of a place in a choice border, it is a subject that may be used with good effect among shrubs, in open woodland or some neglected corner. One of the Malvaceae, K. vitifolia can claim no small share of that decorative quality which belongs to so many of its kind. A stately, upright grower four or five feet high, its very large, vine-shaped leaves, in a lively green are distinctly attractive. The flowers, which are cup-shaped and about the size of those of a Hollyhock, are borne singly at the leaf-axil during the middle of summer, the corollas being pure white or blush. If these will be a disappointment to gardeners who like their colours strong, there is to some of us a decided attractiveness in such delicately-textured blossoms hovering in the shade of the widely-disposed, handsome leaves.

K. vitifolia is a native of Hungary, its generic name commemorating Paul Kitaibel, the Austrian botanist. The plant is quite hardy and does well in any average loam, and few subjects are more readily satisfied, either in sun or shade. It was this species, it will be remembered, that was used with Abelia Thompsoni; in the production of that curious graft-hybrid, K. Lindemuthii, an oddity which I could never succeed in growing with any satisfaction. *A. T. J.*

ALPINE GARDEN.

SILENE SCHAFTA.

ALTHOUGH well-known to most lovers of alpine flowers, there are yet many whose gardens would be enriched by the presence of the bright little plant named Silene Schafta, which has been in our gardens since 1844, when it was introduced from the Caucasus. It has fully justified its introduction, since it has become so accustomed to our climate that it has laughed to scorn the trials and storms of our winters, and has given with no sparing hand its gifts of bright flowers in the late months of the year. By some slip—and there are few works of reference without some such failing—the flowering period of S. Schafta is given by one authority as "April," which, as everyone who knows the plant will agree, is an error, and anticipates the flowering by three or four months. With the writer, S. Schafta generally begins to bloom in August, and its bright blossoms are not only welcome at that time, but are doubly so, seeing that they are continued for many weeks and even the first frosts fail to destroy them, and very fascinating they are with their bright, rose-pink or magenta blooms silvered over by the hoar frost.

This little Silene forms a mass of green leaves, which are very pleasing when trailing over the rocks, down a retaining wall, or as an edging. The flowers are of good size and are of that hue which some call magenta, but others claim to be rose-pink. Even if we admit that it may be magenta, there is plenty of greenery about the plant to neutralise any hardness of colour. Its behaviour in the garden is beyond reproach. Farrer tells us that "So lavishly does it grow, indeed, and so riotously bloom, that it loses the refined air of endurance which ought to be associated with an alpine perennial, and takes on the look of some bedding annual, ebullient in blossom because ephemeral." But, as he states, also, that "S. Schafta is perhaps one of the rock-garden's greatest assets in late summer and autumn" we have to "forgive (as we can easily do) any shortcomings of the summit of perfection;" and rejoice in its health and happiness and in the benison of bright bloom it bestows upon our gardens for so long. No one need be without it, as it comes freely and easily from seeds, and may also be propagated by cuttings. It appears to have no foibles respecting soil or exposure, but flourishes in loam or in orthodox rock garden soil, while it blooms in sun or shade, provided that the latter is not too dense.

ODONTOSPERMUM MARITIMUM.

It is a long time since I came across the plant known as Odontospermum maritimum, and also as Asteriscus maritimus, the former being now the recognised name. The other day, however, a flower of this plant came to me from a local rock garden, and it reminded me of this Odontospermum having been shown in Edinburgh many years ago by a Scottish firm that intended specialising in alpine flowers, which they had not done previously. With a plant of its appearance, some of us who had been growing alpines for years were doubtful about its hardiness, and asked the firm's representative about this, but could obtain no assurance of its ability to withstand the winter. On further inquiries made in other quarters I came to the conclusion that it was not worth while to procure O. maritimum.

Until the other day I had not seen it growing in a Scottish garden, and I fear that in the place whence the last specimen came it will succumb. With regard to the appearance of the Odontospermum, one may state that it is a Composite with wonderfully large, golden-yellow flowers, and silky-woolly leaves. It is a plant which, if hardy, would attain a certain amount of favour. It was figured in *The Gardeners' Chronicle* in 1884 (Vol. XXII, p. 392, Fig. 70). Farrer is not very complimentary to the genus, about which he wrote :—

> "They are hardly hardy with us, nor very well worth the trouble of trying, were it not that failure would bring so little disappointment."

One can only write of this plant from the Mediterranean regions with very faint praise, but those in very mild localities may not think it unworthy of a trial. *S. Arnott.*

SEMPERVIVELLA ALBA.

This is a really charming plant when grown, as I recently saw it, on rock work in a cold house; the plant is a velvety, soft green in colour, with the general appearance of a Houseleek; the flowers, produced on numerous sprays, are round and comparatively large, not quite pure white in colour and best described, perhaps, as ivory.

The plant flourishes in a light, sunny position, and in a well-drained, light and gritty soil; it is, I think, of doubtful hardiness, but my experience is entirely of plants grown in the alpine house.

S. alba is as yet rather rare and should, when better-known, prove very popular; the large flowers are decidedly pretty, and the whole plant is of interesting appearance. *Ralph E. Arnold.*

HARDY FLOWER BORDER.

SISYRINCHIUM STRIATUM.

Introduced from Mexico so long ago as 1788, Sisyrinchium striatum has never become a popular plant, although it is listed by a few dealers in hardy flowers, and is to be seen in some gardens. I have observed it grown on rock gardens, but it appears to me that its proper place is in the border, where, not far from the front, the sword-like leaves, from one foot to two feet high, and yellow flowers, about the size of a shilling, are interesting and give variety to the border, even although they can hardly be described as brilliant. This Sisyrinchium is one of a large family of plants, some of which are of exquisite beauty, and a goodly number of which are only half-hardy in our climate.

I have found S. striatum to be one of the plants which occupy the borderland between hardy and half-hardiness. Ordinarily, it withstands the winter if in a dry, sunny border, but in some seasons may depart this life, whether owing to winter wet or frost, I cannot state. But it frequently reproduces itself from self-sown seeds, and rarely disappears.

It is increased by seeds and division of large plants. Not a first-class, but an interesting, border flower, S. striatum is favoured by some. There is in existence a variegated variety, S. s. var. variegatum, with the leaves striped with gold. *A. D.*

CLEMATIS INTEGRIFOLIA.

It was with pleasure that I read the article on this old plant by *G. S. T.*, on page 222. To the two varieties mentioned by your contributor, I may add a white one, C. integrifolia var. alba, and one named Durandii, which I have no recollection of having seen, but which is offered by an English nursery. There was also a double variety, which I saw offered many years ago, but would appear to be lost to cultivation as I have heard nothing of it since.

It is a pity that the increase of C. integrifolia is difficult, but on one occasion I divided a large plant and the divisions grew quite well afterwards. As your correspondent states, C. integrifolia resents disturbance. *S. Arnott.*

BULB GARDEN.

CRINUMS AND AGAPANTHUSES.

I enclose a photograph (Fig. 145) of Crinums and Agapanthuses growing in one of the public gardens here. Both kinds were planted about three years ago, in not too favourable a situation, as the site is fairly exposed and faces east. They had no care in the way of protection during the winter months, and it is, therefore, all the more surprising they have withstood the winter so well, as the situation they occupy is rather wet, owing to water draining from the slope behind. This latter may, however, account for them growing so freely during the past dry summer, as the colony has received no water.

The Crinums are C. Powellii and C. P. var. alba; the Agapanthus is the old A. umbellatus. All were rather past their best when the photograph was taken (September 20), but the illustration may tend to show that the climate here is not so severe as supposed. *J. Clark, Corporation Nursery, Scarborough.*

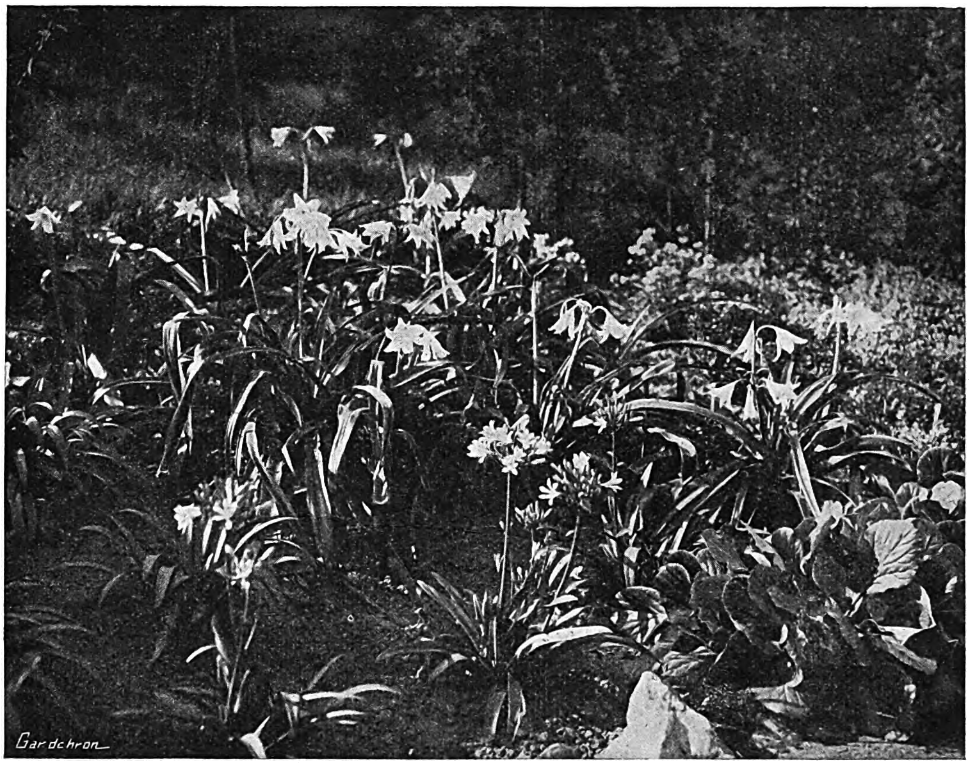

FIG. 145.—CRINUMS AND AGAPANTHUSES AT SCARBOROUGH.

BOG AND WATER GARDEN.

SENECIO CLIVORUM VAR. ORANGE QUEEN.

Senecio Clivorum has long been recognised as a desirable plant for bold groups by the water side and elsewhere. The variety Orange Queen is, however, a great improvement on the old form. I am convinced that anyone who grows this variety will at once discard the type. Big groups of Orange Queen planted by the stream in one of the public gardens here, have been the admiration of numerous visitors this season. The seeds were procured from Messrs. Barr and Sons, some three or four years ago, and I still find seeds listed in no other catalogue but theirs, although several other nurserymen are now listing plants. The seeds germinated freely, the resulting plants making strong flowering specimens in two years; every one is true. I believe it is, if anything, stronger growing than the old form, and the season of flowering is longer, as even now (October 5) the plants make a good display of colour.

The chief features of this new variety are its larger flowers and much better colour—a rich, glowing orange, much deeper and brighter than in the old form, which by comparison is decidedly dull and weedy. *J. Clark, Scarborough.*

INDOOR PLANTS.

STREPTOCARPUS WENDLANDII.

This old species is not to be compared, for floral beauty, with the exquisite hybrids now in commerce, yet by virtue of its singular habit of growth it is invariably an object of interest and distinction; one large, reflexed leaf is produced and this will sometimes attain a width of two feet, with proportionate length. From the midrib of this leaf scapes are produced to a height of twelve to eighteen inches, bearing very charming, violet-blue and white flowers.

This interesting species is easily raised from seeds, or the large leaf may be used for propagation. S. Wendlandii has been used as a breeder, but not to the same extent as S. Dunnii, another singular species introduced from the Transvaal, in 1886; this, too, has only one large leaf, sometimes a yard long and half-a-yard wide, from the base of which the flowers are produced in crowded and erect panicles, the colour being an attractive shade of brick-red.

With S. Rexii, S. parviflorus, S. polyanthus and S. Fanninii, these Streptocarpi have helped to produce the lovely varieties known to-day. Both S. Wendlandii and S. Dunnii grow freely in a good compost of loam, leaf-soil and sand, with the addition of a little well-rotted manure. The best results are obtainable in an intermediate temperature, but quite good plants may be grown in an ordinary cool greenhouse. *R. A.*

TETRANEMA MEXICANA.

This pretty little perennial herb is a member of the Natural Order Scrophulariaceae. It represents a monotypic genus hailing from Mexico, and was introduced to this country during the year 1843. The generic name Tetranema refers to the stamens or filaments, which are four in number, being characteristic of the plant. The flowers are borne in great profusion on axillary, scape-like peduncles. They are a delightful shade of purplish-violet, somewhat variegated by a paler shade of the same colour. The rich, dark green leaves are obovate or oblong and entire, and both the upper and lower surfaces are glabrous.

Culture in a warm greenhouse is most suitable to this Mexican Foxglove.

Propagation may be effected by means of division of the old plants, and by seeds, which set very freely.

Panning should be done in spring, using pans twelve or fifteen inches wide, and putting four or five good young plants in each. A compost of good sandy loam and leaf-mould should be found to suit admirably. An abundance of bloom is given by the plant during the greater part of the summer months.

GLOXINIA MACULATA.

This elegant stove subject was introduced to cultivation in this country so long ago as 1739, and is a native of South America.

The downy, purplish-blue flowers are over an inch in diameter, and are borne in a large spike. They expand in succession from the base, and remain open for three or four days. A very much deeper blotch of purple in the centre lends beauty and contrast to the other floral parts. The cordate leaves are about four inches in length by three inches wide; the upper surface is shiny and has a few stiff hairs here and there; rich red suffuses the reverse of the leaf and, indeed, the whole plant generally.

The roots should be started into growth during February, in a temperature of 65°, a suitable compost being one of equal parts of good Oak leaves and rough peat, with just a dash of silver sand and charcoal to ensure sweetness. They may be put straight into flowering pots, either six inches or seven inches in size, or placed in small pots first and then potted on when well rooted.

Liquid-manure applied frequently when the blooms begin to appear is very helpful.

The maximum height of this subject is about two feet, but as the stems and leaves are extremely fleshy, great care should be taken in attending to them, otherwise they will be very liable to break off.

After flowering, when growth begins to decline, the supply of water should be reduced gradually, and when the growths have died down, the roots should be stored in a suitable dry place. but never allowed to suffer from cold. *F. H. Wright, Cambridge Botanic Garden.*

THE GENUS PRIMULA.

(*Continued from p.* 290.)

SCHLAGINTWEITIANA (Pax). Schlagintweit's P.
(Denticulata).

A dwarf, non-mealy, perennial species with a tuft of oblong-spathulate, blunt leaves three-quarters-of-an-inch to one inch long and about half-an-inch wide, gradually or abruptly contracted into a winged stalk, equalling or shorter than the blade; margins sharply and irregularly toothed; both surfaces minutely downy. Flower stem slender, two-and-a-half to four-and-a-half inches tall, bearing a dense, many-flowered head of lilac blossoms. Corolla about half-an-inch across, with broadly heart-shaped, notched lobes; tube more than twice the length of the calyx.

Grows in damp, rocky places between Rilkot and Milum, in the western Himalayas, at about 11,000 feet above sea-level.

Culture: As for P. denticulata, is suggested.

SCIOPHILA (Balf. f.). Nivai P.
(Bella).

A beautiful, dwarf, densely tufted, perennial sub-species of P. bella (Fr.) with a somewhat woody rootstock clothed with the dried remains of previous seasons' foliage. The rosettes of bright green leaves have oblong or nearly circular blades about two and-a-half inches across, on narrowly winged stalks from two to four inches long; under surface coated with yellow meal. Flower stem extremely short, under one-eighth-of-an-inch long, bearing one pale, or deep purple blossom, subtended by two bracts. Corolla about one inch across, more or less flat, cut into five broadly heart-shaped, bifid, deeply divided lobes; tube pale purple, with deeply coloured veins, cylindrical below, dilated upwards, with a dense tuft of snowy-white hairs in the throat. Flowers in July.

Grows in damp, very shady spots in moss or in clefts of rock on the ridge of Naung Chaung, Nivai divide, in Upper Burma, at about 13,000 feet above sea-level.

Culture: Peat and moss mixed with limestone chips in a damp, shady spot, should suit this plant.

SCULLYI (Craib). Scully's P.
(Petiolaris-Sonchifolia).

A dwarf, non-mealy, large-flowered perennial species with a stout rootstock which bears a rosette of narrowly oval, oblong, or oblong-ovate, papery leaves about two inches long and one-and-a-quarter inch wide, nearly stalkless, or tapering to a distinct, winged stalk an inch or more in length; margins furnished with sharp, irregular teeth; both surfaces more or less smooth. Flower stem obsolete; flowers numerous, borne on minutely downy stalks one to one-and-a-half inch long, after the manner of the Primrose. Corolla about three-quarters-of-an-inch across, with egg-shaped, elliptic or oval-oblong, pointed or blunt, irregularly sinuate-lobulate segments; tube about five-eighths-of-an-inch long.

Grows in damp situations near Longlu and Singaleelah, at 12,000 to 13,000 feet above sea-level, in the west Sikkim Himalayas.

Var. Searightii (Craib) has long, narrow lobes to its calyces which are externally nearly smooth.

Culture: As for P. petiolaris.

SECLUSA (Balf. f.). Burmese Downy P.
(Cortusoides).

A robust, coarse-leaved, deciduous, perennial sub-species of P. mollis (Nutt.), with a tuft of membranous leaves from eight to ten inches long, with rounded, heart-shaped blades about six inches across, on woolly stalks; margins furnished with sinuate lobes, edged with numerous horny-tipped teeth, fringed with fine hairs; both surfaces moderately clothed with short, white hairs. Flower stem robust, downy, about fifteen inches tall, bearing two to three superposed umbels composed of six to eight deep crimson blossoms with somewhat paler lobes. Corolla slightly oblique, membranous, about half-an-inch across; segments egg-shaped, fringed, tips cleft; tube cylindrical, equalling the calyx in length, with a ring in the mouth. Flowers in June. In cultivation in 1922.

Grows in damp, usually deeply shaded situations, in evergreen forests and shady thickets, in southern Yunnan and Upper Burma, at about 8,000 feet above sea-level.

Culture: Plant it in a compost of good, rich, heavy loam and leaf-soil, and treat as a cool greenhouse plant. *A. W. Darnell.*

(*To be continued.*)

NOTES FROM A CAMBRIDGESHIRE GARDEN.

The following notes on how some young trees and shrubs in a Cambridgeshire garden have weathered the frost and drought of this abnormal year may be of interest, and, perhaps, some encouragement, to readers of this journal.

The garden in question lies almost midway between Cambridge and Huntingdon, and just inside the Cambridgeshire boundary. The subsoil is gault, with patches of gravel here and there, and in some places a heavy clay comes right to the surface. It is barely fifty feet above sea-level, and is protected by a screen of trees from the north-east and east winds which arrive from the North Sea, without other let or hindrance, over sixty miles of fenland.

The frost of the early part of the year was the most severe since 1895, 20° having been registered on February 13, and 18° on the 12th and 14th, while so late as March 17, 10° were recorded. The rainfall to date—September 30—has been 8·55 inches. The yearly average, taken over the last thirty years, is 24·15 inches.

The majority of the plants referred to hereafter were planted last fall, and many of them had barely been put into position when bitterly cold winds fell upon them in mid-December, accompanied by a frost which did not lift to any appreciable extent until the general thaw in late March. It is, therefore, all the more remarkable to note how very little they seem to have suffered. Furthermore, as no water supply is laid on to the garden, it was not possible to water any of the plants, except some of the Rhododendrons, until early September, when, owing to some particular shrubs looking a little dejected, they were watered at great labour from a pond at some distance. The Rhododendrons in permanent positions had been treated all the summer with a liberal mulch of Oak leaves, and those in the nursery had been watered by means of large flower-pots sunk in the ground at intervals and filled up with water every four or five days. A few other plants in the nursery were catered for in the same way, and non-Ericaceous shrubs in permanent places were treated with a mulch of lawn-clippings (reluctantly spared from the Adco heap!), and with Horse Chestnut, Lime and Elm leaves.

Cotoneasters (bullata, Henryana, bacillaris, salicifolia), Stranvaesia Davidiana and its variety undulata, and Photinia villosa, although planted in full sun, look as fresh and green as if they had had their normal supply of water; as also do three species of Arbutus, viz., Andrachne, hybrida, and Menziesii. In fact, the latter has made a lot of new growth, and looks perfectly happy in the middle of what had, by mid-September, become such an arid plain that one expected it to sprout Cacti!

Davidia Vilmoriniana had begun to droop by the end of August, and to lose a number of leaves from one branch, but a heavy watering in early September restored it in twenty-four hours and carried it through the next three weeks. Acer Hersii did not appear to have felt the drought, but was watered as a precaution.

A number of plants in the nursery, including Salix magnifica and S. Bockii, Pterocarya stenoptera and P. rhoifolia, Aesculus turbinata and A. indica, Nothofagus procera and Juglans Sieboldiana, showed no signs of suffering from drought, but were watered as a precaution. It might here be mentioned that Salix magnifica, about three feet high, did not appear to have been harmed at all by the winter or spring frosts. It, and the plants of Juglans Sieboldiana (which last year were badly cut), were protected through the winter by a lath screen laid on posts a foot or so, horizontally, above them. These lath screens have also protected from the sun, with marked success, beds of small seedlings of Cercidiphyllum japonicum, Abies sachalinensis, and various Cotoneasters and Barberries, which otherwise would have been exposed to full sun. The screens used are made of one-inch laths spaced half-an-inch apart.

Plants in the nursery which have not been watered, and which in spite of a big surfeit of sun and little shade, show no signs of distress, include Zelkova acuminata, Idesia polycarpa, Rhus semi-alata, Celastrus articulatus and Pyrus transitoria (Malus toringoides).

A number of Poplars (Populus koreana, P. Rasumowskyana, P. yunnanensis, P. trichocarpa, P. szechuanica, P. lasiocarpa, P. marilandica and P. Eugenei), would have looked the fitter for water, but, unfortunately, it was not possible to assuage their thirst. In protest, they began to shed their leaves very early, and now look more like mid-winter than early autumn. A large plant of Populus Wilsonii has, I am afraid, been killed.

Two trees of Betula utilis have not come through this trying time, but as they were seven feet high when planted in March, their decease is not altogether unexpected; although Betula Ermanii has not been affected under almost similar conditions.

Just before Christmas this garden was enriched by a very welcome gift, from a famous Cornish garden, of three plants of Rhododendron sinogrande, one plant of R. arboreum (Sir Charles Lemon), a fine plant of Viburnum fragrans, and the Populus Wilsonii mentioned above. These had all been planted barely ten days when the frost came, and with it the drought. As might be expected, the three plants of R. sinogrande soon showed signs of acute distress. Their magnificent, twenty-inch leaves turned brown and black, and before a month had passed they were as hideous as they had on arrival been beautiful. But having great faith in the donor's opinion that they should thrive even in so inclement a climate as west Cambridgeshire provided, they were treated well; we did not take up and burn these distressful relics, and soon after the beginning of May we were rewarded by the sight of new leaves growing out from the base of the dead foot-high stems. These stems were then cut away, and in a few weeks the leaves, five or six inches long, were making determined efforts to take the place of their deceased elder brethren. Unluckily, however, the efforts of the largest and best were frustrated by a rabbit which succeeded in getting inside the wire-surround, and it now has to make a renewed effort.

The plant of R. Sir Charles Lemon has never once looked back. It has been watered regularly, but the frost apparently did it no harm, and it has made a lot of new growth. It holds up it leaves at a healthy angle, displaying well the lovely rust-red tomentum. A plant of R. Loderi received from another source and planted out about the same time, has also come through so far with flying colours, and looks as healthy as possible.

Viburnum fragrans seems to have suffered neither from frost nor drought; nor has a three-foot specimen of Eucryphia Nymansay. The latter, however, had been planted twelve months before the drought came, so may have sent its roots down to dampish soil.

A collection of foreign Oaks is being made here, and of the sixty-odd species already represented, about twenty-five are planted out in permanent positions, the remainder being yet in the nursery. The former have come through with no apparent damage, except that a fine young plant of Quercus Muehlenbergii, about four feet high, was cut to the ground, or died back, after being moved last November. It has, however, started into growth again from the ground, so it may now establish itself. The same happened with two plants of Quercus (? Castanopsis) concolor and Q. caudata which were received from Cornwall just before the frost at Christmas—they were, apparently, lifeless in April, their leaves having withered up, and they looked only good for the bonfire. But by June they had made new growth, and now look quite healthy.

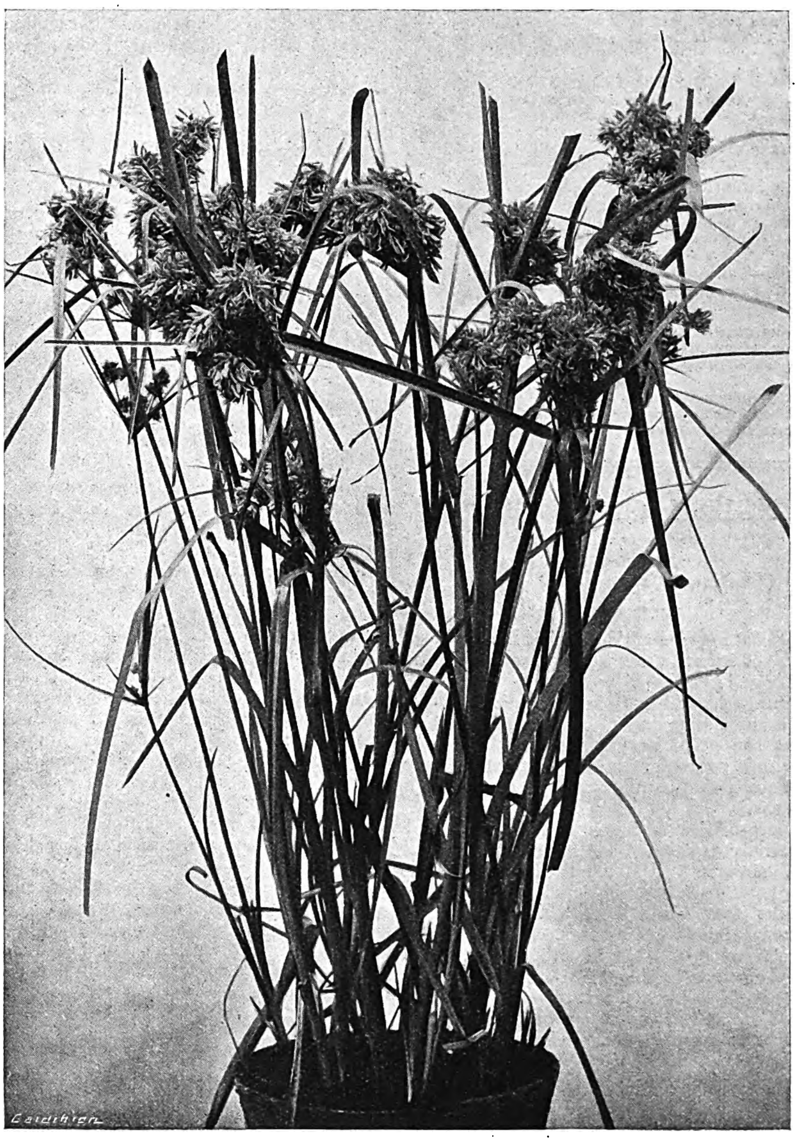

FIG. 146.—CYPERUS CONGESTUS (PARAMATTENSIS ?).
(see p. 307).

Of young Oaks in the nursery, which have had no watering, and a great deal of hot sun and no shade, those which suffered most were the Japanese and American evergreen Oaks, such as Q. glabra, Q. myrsinaefolia, Q. cuspidata, Q. phillyraeoides, Q. chrysolepis and Q. densiflora. Some of these are beyond recovery, but, fortunately, a number of seedlings of similar species are ready at hand to replace them, having grown up among a forest of weeds which were allowed to remain on the seed-bed as shelter.

Young deciduous Oaks in the nursery seem to have suffered very little, the only ones to look really bad being two plants of Q. conferta and Q. Libanii, while Q. Sargentii does not look too well. Five plants of Q. alba look as fit and fresh as possible, as also do plants of Q. pontica, Q. bicolor, Q. Bebbiana, Q. coccinea and Q. Kelloggii.

Beyond the few plants already mentioned as having died, our only other losses have been small plants of Magnolia parviflora and M. hypoleuca, and some Chilian plants, including Embothrium coccineum, Tricuspidaria lanceolata and Mutisia decurrens. It may be early days to congratulate our plants on the way they have come through this trying year, and perhaps we should "touch wood." But if there is any moral in these notes, it is to "hasten slowly" in the scrapping of plant material which may appear to have been killed after a hard winter—*vide* our experience with R. sino-grande and with three young Oaks. This advice was more than once given in these columns last spring by other writers, and to them I am grateful.

The rainfall, month by month, has been:—January, 1·42 inch; February, ·70 inch; March, ·09 inch; April, 1·29 inch; May, 1·13 inch; June, 1·06 inch; July, 2·13 inches; August, ·57 inch; and September, ·16 inch. *R. C. B. Gardner, Connington Hall, Cambridgeshire.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

AN ENGLISH GARDENER IN CHILI.

(*Continued from p.* 228.)

ANOTHER species of Berberis which I have not yet identified is less common than B. Darwinii; it has pale yellow flowers more loosely arranged, and simple, elliptical leaves with, as a rule, only one pair of lateral spines, and one at the point of each leaf; the spines on stems and branches are also much larger (so much as one-and-a-quarter inch) and always set in threes.

In some localities, and growing in open and often extremely dry situations, is found a striking evergreen, shrub by Cassia, which forms dense clumps of dark green foliage, usually about six to eight feet high, occasionally reaching so much as twelve to fifteen feet. It freely produces large flowers of a bright golden colour and obviously belongs to Leguminosae. Another plant very conspicuous when in flower is a large evergreen Composite, most probably Senecio species; it has simple, entire, viscid leaves, about three inches long, and large, cymose inflorescences, the individual flowers being quite three inches across, and with ray florets broad in proportion.

Forming an effective contrast with this coarse-growing plant is the delicate-looking Fuchsia rosea. The flowers are small but plentiful and brightly-coloured, the corolla tube and sepals being rose-pink and the petals purple, effectively shown off by the small, bright-green leaves. This species makes a sturdy bush so much as eight feet high and several feet through; it also drops its leaves in drought, and the extremely succulent branches remain dormant until the rains.

Another plant peculiar to Chili is the gigantic Lobelia, L. Tupa, which grows ten to twelve feet high, the inflorescences being at least two feet long, and the individual flowers two inches. A closely allied species of similar habit, which I believe to be L. polyphylla, has dark chocolate or maroon flowers.

Climbing among the branches of the shrubs and trees, and with their roots in the decomposing leaves, are two species of Mutisia, M. ilicifolia and M. subulata, the latter being by far the best. M. ilicifolia has large flowers of a soft pink colour two to three inches across, but the plant is spoiled by the old dead leaves which are persistent and give it a very unsightly appearance. In Mutisia subulata the foliage is altogether finer and more graceful, and the flowers are brilliant scarlet.

Two perennial species of Eupatorium take advantage of the shelter and support of stronger shrubs, one having rose-coloured flowers and the other white. The same means of obtaining protection and light is employed by many perennial species of Calceolaria, although some of them make compact little bushes. Of this genus there are innumerable species; I have found so many as eight distinct species growing in one small valley, two of these being semi-aquatic (C. sonchifolia and C. scabiosaefolia). The most common species is C. corymbosa, and to my mind the best is one with very small, linear leaves and masses of bright golden-yellow flowers.

An equally well-known genus found here is Salpiglossis. S. sinuata flowers freely and reaches three or four feet high; it would, however, cut rather a poor figure if staged alongside present-day hybrids.

A lovely little plant which rejoices in a hot, dry bank, or similar situation, is a brilliant blue Sisyrinchium. Its flowers are fully two inches across, the golden stamens and styles contrasting well with the colour of the petals; it rarely grows more than four to six inches high. There are many other species of this genus, one which has thick, perennial, equitant leaves, and throws up an inflorescence so much as three feet high, with disappointing white flowers. Two other species have bright golden flowers, one only growing six inches and the other eighteen inches high.

Another lowly subject which delights in a hot, dry place is Stenandrium dulce, a tiny plant rarely more than two or three inches high, but belonging to that family of large, often coarse plants, Acanthaceae. Reference to my notebook gives the following details—"Flowers carried in small inflorescences on peduncles one-and-a-half-inch long, each flower arising from a bract three-eighths-of-an-inch long, and hairy. Colour, pink; petals being about half-an-inch long, gamopetalous, with tube half-an-inch long; two stamens are situated half-way down the tube and parellel, vertically, with it. Pistil three-eighths-of-an-inch long with forked stigma. Leaves simple, entire, ovate, dark green above, grey-green under. Whole plant covered with short, stiff hairs." The habit of the plant always reminds me of a Primula.

Side by side with this plant grows Verbena erinoides, the best species which I have ever seen here. It has clear rose-pink inflorescences and forms tufts six or eight inches high, but it is somewhat straggling in habit.

One of the earliest plants to flower after the rains is a small Oxalis; in some localities it covers large areas with a close carpet of gold about one inch to two inches high. Its flowers, fully expanded, are about one inch across and borne singly. It propagates rapidly by means of tiny bulbils, matures early and dies off, disappearing entirely until the following winter. *G. W. Robinson.*

(*To be continued.*)

SOME NOTES ON SALVIAS, ECONOMIC AND NATIVE.

THE extensive genus, Salvia, which contains so many beautiful species, is not well represented in Britain, there being only two native species, S. pratensis, L., or Meadow Sage, and S. Verbenaca, L., or Wild Clary.[*]

The latter is a rather coarse-growing perennial, attaining on an average a height of about one-and-a-half foot or more, and bearing whorls of rather small flowers, of a blue colour, which form terminal hairy spikes. The plant favours roadsides and waste places, especially on a gravelly soil, and is to be found, here and there, scattered over England, Ireland and the southern part of Scotland, although not in sufficient abundance to warrant it being described as a common British plant. A variety with purplish-red flowers, var. rubella, Jord. and F., has been found near Kew, in Surrey, and is justly described as very rare. The name Clary is derived from the Latin "*sclerea*," which has become corrupted to "Clear-eye." The reason for this is that the seeds contain an abundance of mucilaginous matter, and at one time it was customary to place one of the seeds in the eye so that the mucilage might remove any adventitious matters from it, thus rendering it more clear.

Salvia pratensis, our other native member of the genus, is an extremely beautiful plant. Like S. Verbenaca, it is a perennial, but it attains a greater height, and its flowers, borne in whorls forming a long, terminal spike, are much larger and of a gorgeous shade of blue. It is also characterised by the paucity of its stem leaves, by the shape of its radical leaves, and the fact that these are very much wrinkled.

Although not strictly an alpine plant, S. pratensis grows very abundantly in alpine and sub-alpine meadows and pastures, sometimes, as I have seen in Switzerland, occurring in such abundance as to make a mountain meadow appear quite blue from a distance. In Britain it is extremely scarce. There used to be a plant or two growing wild near Oxshott Station, in Surrey; but building operations have taken place there recently, which, I think, have destroyed it. At any rate, I could find no trace of the plant when I re-visited the spot last year. In Kent, however, there is a rather inaccessible wood, on one border of which this handsome Salvia grows in abundance, to which I generally make an annual pilgrimage for the pleasure of admiring it. Fortunately, the wood is well removed from the haunts of trippers, so there is little danger of the plant being exterminated. It was first recorded for this spot in 1699. The plant has also been recorded for a number of other English counties, but I have not seen it in these stations.

From the economic point of view, the most important member of the genus is undoubtedly S. officinalis, L., the common garden Sage, a native of southern Europe, of which many varieties have been produced as a result of cultivation. As a culinary herb, it stands in high repute, being especially palatable and wholesome as a seasoning for rich dishes, such as duck, goose and pork. At one time it was very highly valued for its medicinal properties, the name "Salvia" being derived from the Latin *salvere*, to be saved, the popular name of "Sage" being a corruption of this.

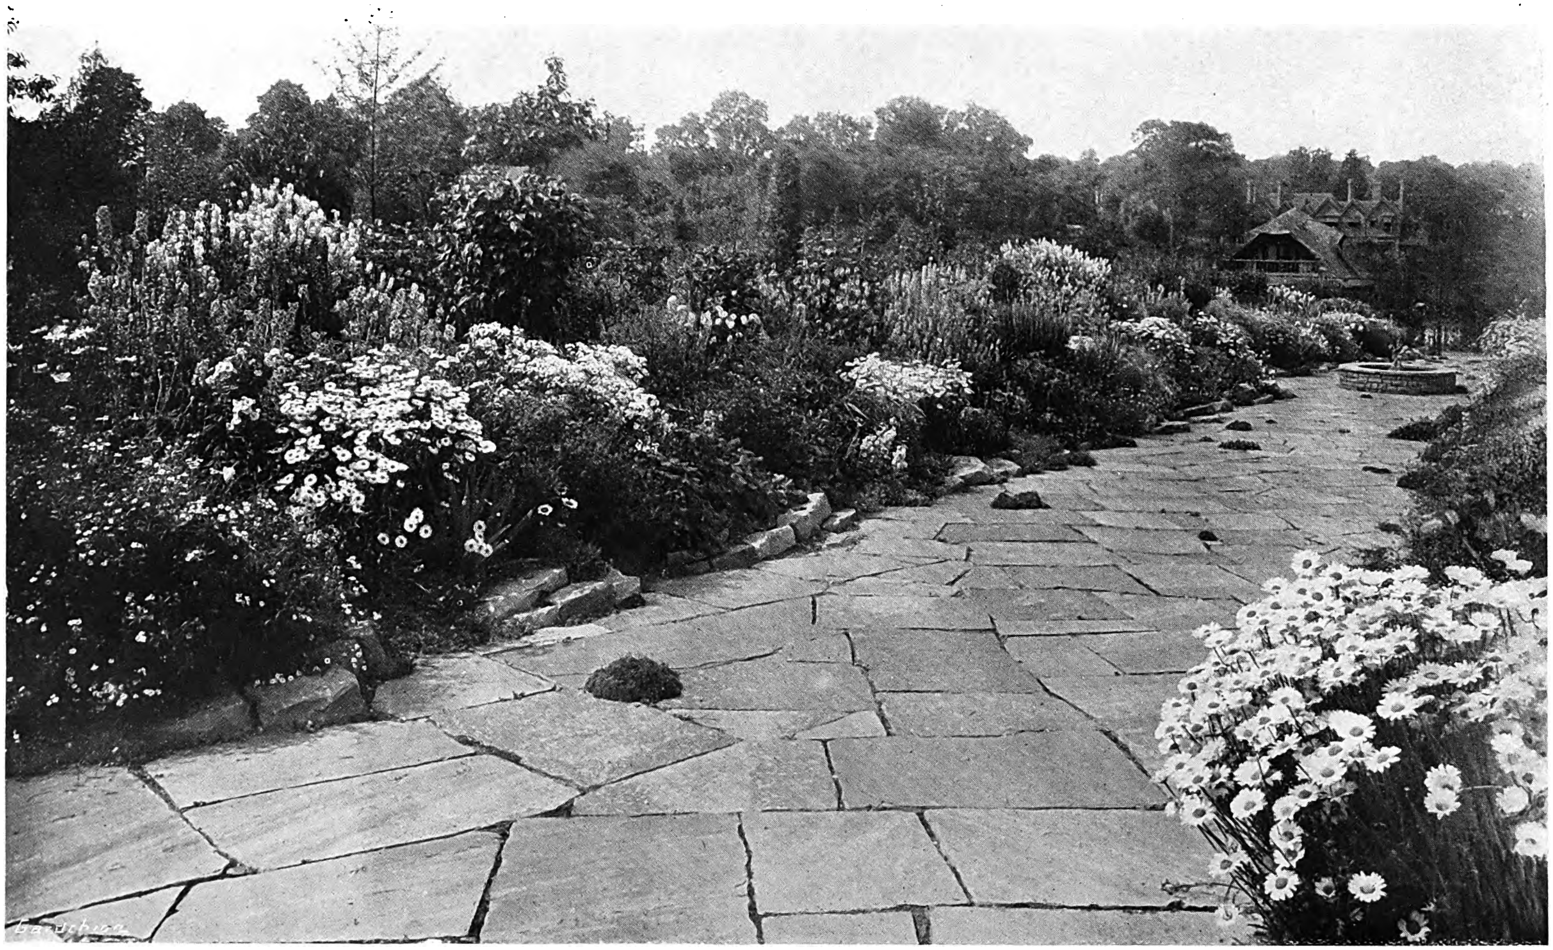
Nowadays, Sage is no longer an official drug in Great Britain, but the following quotation from Dr. Parkin's edition of Culpeper's *English Physician* will give a good idea of the wonderful medicinal properties which were at one time attributed to it.

"Jupiter claims this [the Sage] and bids me tell you, it is good for the liver, and to breed blood. A decoction of the leaves and branches of Sage made and drunk, saith Dioscorides . . . . causeth the hair to become black. It stayeth the bleeding of wounds and cleanseth foul ulcers and sores . . . . Orpheus saith, three spoonfuls (sic) of the juice of Sage, taken fasting, with a little honey, presently stay the spitting or casting of blood in them that are in a consumption. . . . Matthiolus saith, it is very profitable for all manner of pains in the head, coming of cold and rheumatic humours, as also for all pains of the joints whether inwardly or outwardly, and therefore helpeth the falling sickness, the lethargy, such as are dull and heavy of spirit, the palsy, and is of much use in all defluxions of rheum from the head, and for the diseases of the chest and breast . . The juice of Sage taken in warm water helpeth a hoarseness and cough . . . Sage is of excellent use to help the memory, warming and quickening the senses," and so on, this plant, indeed, seeming to have been regarded as a veritable cure-all. In the

---

[*] A variety of the latter (Marquandii, Druce) with pale blue flowers rather larger than in the type, which occurs in Guernsey, may perhaps be entitled to specific rank, thus increasing the number to three.

Supplement to THE GARDENERS' CHRONICLE.



HERBACEOUS BORDERS AT THE MANOR HOUSE, STANMORE.

quaint English of rhymed botanical treatise based on Macer's mediaeval herbal—

> " Why of seknesse deyeth man
> Whill sawge [Sage] in gardeyn he may
> han."

Although, as might be expected, Culpeper's recital of the virtues of Sage is largely a farrago of nonsense, the plant is certainly not destitute of physiological action. It has carminative properties, whence its real utility as a condiment, and has been employed in the treatment of indigestion. On distilling Sage with water, a small quantity of a greenish-yellow volatile oil of penetrating odour is obtained. This, administered in sufficiently large doses, is stated to induce convulsions resembling those of epilepsy.

The oil, it may be mentioned in passing, is used to a limited extent in soap perfumery.

Another Salvia of some considerable economic importance is Garden Clary, S. Sclarea, L., a native of the south of France, Italy and North Africa. To this plant, which has been grown in English gardens for centuries, many wonderful medicinal properties have been attributed; but we may pass over these and consider the real use of the plant as a source of an essential oil of great value in modern perfumery. This oil is obtained by distilling cultivated plants or, preferably, only their flowers, with water in the perfumery factories of Grasse, in the south of France. It is known as " Clary Sage Oil." The odour of the oil is peculiar and attractive; it is reminiscent of Muscatel wines with a background, so to speak, of ambergris. It is especially useful in the compounding of certain perfumes from synthetic ingredients, as it endows them with a note of naturalness, a property due to its Muscatel-like odour. Although, at present, not a great deal of S. Sclarea is cultivated for perfumery purposes, there is a good demand for the oil, and a bright future for the plant.

The Muscatel-like odour of Clary has, it is stated, been taken advantage of by certain German wine merchants, who have used the plant to convert Rhinish wines into so-called " muscatels." The powdered flowers are also used, more especially in Turin, as an essential flavouring ingredient in the preparation of vermouth.

Uses have also been found for the Clary Sage water obtained along with the oil, when the plants or flowers are distilled, and which is pleasantly fragrant. It is employed in making certain wines and also as a diluent in the manufacture of liquid dentifrices.

In conclusion, it may be noted that the name of " Sage " has been bestowed on a number of other plants besides Salvias. One of these, Teucrium Scorodonia, L., is known as Wood Sage. It is a common plant in Britain, growing in woods and Heathy places, and has rather inconspicuous, yellowish-white flowers. It remotely resembles a Salvia. Other plants, not resembling Salvias at all, have no doubt gained the name of " Sage " on account of their real or imaginary medicinal properties. *H. S. Redgrove, B.Sc., A.I.C.*

PLANTS NEW OR NOTEWORTHY.

SALIX MATSUDANA, KOIDZ.

THIS interesting and attractive Willow is a native of North China, Manchuria and Korea. It has been described as the Chinese Babylonian Willow, and, in fact, the first specimens collected were indentified as Salix babylonica by Franchet and others.

Growing trees of S. Matsudana are readily distinguished from S. babylonica by their more upright habit, and the greenish, or yellowish, twigs, those of S. babylonica being a distinct reddish-brown or purplish colour. The leaves are narrow-lanceolate, two to four inches long, and one-third- to three-fifths-of-an-inch broad, bright green above, glaucous beneath.

S. Matsudana was introduced to America from Korea by Mr. J. G. Jack in 1905. The specimen illustrated (Fig. 147), was sent to Kew from the Arnold Arboretum, as a small tree, in 1913, with the information that it was a Willow (Purdom 281) collected by the late Mr. William Purdom in North China.

The tree is cultivated extensively in north China, and is the common Willow of Pekin. While it is a very useful tree for waterside planting, Mr. E. H. Wilson describes this Willow as thriving in China under the ordinary drier conditions of street, roadside and park. Certainly two specimens at Kew have withstood the dry conditions of the past summer well, in fact, better than some of our native trees.

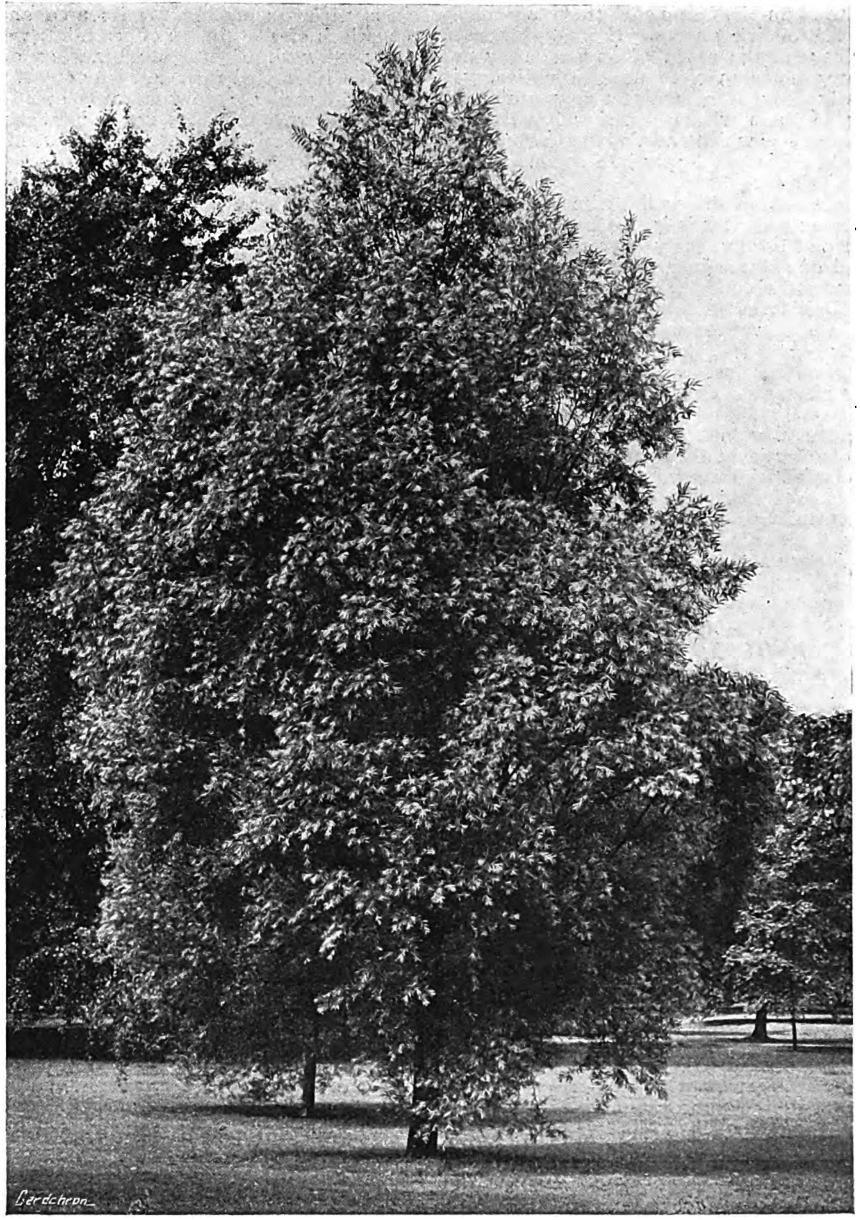


FIG. 147.—SALIX MATSUDANA.

The number of botanical species and hybrids of Salix is very large, but among them the Willows which make attractive specimen trees with good trunks are comparatively few. To these, S. Matsudana will be found a useful and distinct addition for pleasure ground, avenue, park and waterside planting. *A. Osborn, Kew.*

CYPERUS CONGESTUS (PARAMATTENSIS ?).

A FINE species of Cyperus has been shown on several occasions this year by Mr. Amos Perry, Enfield, who has usually had one or more specimens of it, in pans, in his displays of aquatic plants. Naturally, it bears a recognisable family resemblance to such an old favourite garden plant as Cyperus alternifolius (by the way, has anyone seen the variegated form of C. alternifolius during recent years ?), while cultivators of stove plants will have remembered the tall Cyperus Papyrus that was cultivated at one period in some private collections but is now seldom seen outside a botanic garden.

The newcomer (Fig. 146) appears to be more or less hardy. It was exhibited as Cyperus paramattensis, and, paradoxically, if it is the real C. paramattensis, then its correct name is C. congestus, a South African species that has been named C. Paramatta, Mart., then changed to C. paramatta, and later, to C. paramattensis, Link.—which is C. congestus.

This aquatic, new to gardens, is of sturdy growth, and bears heavy heads of flowers, so much so, that when seeds are formed the heads become heavy and the stems often find some difficulty in keeping them upright. At present C. paramattensis (or C. congestus) is not in cultivation at Kew, but plants are being obtained, and when these have been studied the name now used will be confirmed or otherwise.

The first volume of the *Index Kewensis* lists several hundreds of species of Cyperus and an even larger number of synonyms; from this multitude of synonyms it is obvious that species of Cyperus are not easy to distinguish and determine. But if Mr. Perry has not the right name, and even if it is found that C. paramattensis does not equal C. congestus in this case he has, nevertheless, a capital plant of its class and one which many plant lovers will be glad he has introduced to cultivation.

SOME DWARF VERONICAS.

LARGE as the number is of the rock garden Speedwells in common cultivation, the genus is so extensive that there is, outside the range of the more familiar ones, a useful selection of much interest and merit. Some of these are dealt with in the following notes. If none of them is rare, or beyond the reach of anyone, they are sufficiently uncommon to deserve notice, yet sufficiently easy of recognition to permit one to refer to them without getting involved in the difficulties which await the adventurer who would delve too deeply into the labyrinths of a conflicting race.

V. canescens might well claim a foremost place among such, for it is a plant that is not common and hardly likely ever to be, yet is possessed of extraordinary charm. With hair-fine stems and tiny leaves it films the cool but gritty soil it loves with a lacework of verdure so delicate that Arenaria balearica looks positively gross beside it. This, in itself, may be of so little account in the " furnishing " of the rock garden that the plant may easily be accidentally forked up and cast out. But when, soon after midsummer, this diminutive New Zealander is suddenly transposed from an almost invisible bronzy-green mesh into a fairy carpet of starry Speedwell-flowers in the most entrancing of clear porcelain-blues, it proclaims itself a plant of arresting loveliness, and one that suggests a dozen possibilities. This cheerful little mite is, unfortunately, not hardy everywhere, but it has a pleasant habit of seeding, and as often as not will perpetuate itself with a surviving seedling or two should the old plants perish. I quite thought, after 32° of frost last winter, that V. canescens would certainly never reappear here. A kind friend, sympathising with me in my bereavement, sent me a nice, fresh plant, but at the very end of the season V. canescens proved faithful to its traditions by turning up in the form of a microscopic seedling several yards from the spot occupied by its deceased parents. After which I can with a chastened spirit and a stouter faith continue, when leaves are falling, to label V. canescens with the inscription, *Resurgam.*

At the time of writing (mid-October) most of the Speedwells have better sense than to show their " darling blue," but that quaint species, V. pyrolaeformis, which a defective memory tells me Farrer found somewhere in China, is always ready to bear the tribal banner throughout the darkening days. This curious plant, with its downy, notched, rather strap-shaped leaves, generally re-awakens to life with the autumn rains, and unfurls a six-inch crozier of pretty lavender blossoms which, with the purple-tipped buds, might suggest a Borage rather than a Veronica. If not a brilliant performer, V. pyrolaeformis is an easy, good-tempered, hardy plant that will flower at intervals from spring to November, and one that always attracts the attention of lovers of out-of-the-way herbs.

V. Teucrium var. dubia, of many names and infinite variation, does not come within my scope here, since it is the deservedly well-loved Veronica of every rock garden. But its lovely pure white form is not so often seen as it ought to be, and no less can be stated of the rosy-pink. Both are first-rate plants if not quite so robust as the type, but if one dare make comparison among the daughters of a family who are all so fair, I would give first place to that admirable little plant, V. T. var. alpina. That, at any rate, is the long name which accompanied the gem here, a treasure of comparatively small size, yet with large leaves and enormous flowers in bold, upright spikes of the richest violet-blue. Full of quality as this alpine form of a familiar plant undoubtedly is, it is not less full of the most commendable courage.

If it is of no great value as a flowering plant, V. telephifolia wins its way into our gardens and old pig-troughs by reason of its neat little rosettes of very glaucous leaves, so fleshy, compact and nicely rounded that the unwary might at first glance suppose them to belong to some Sedum. The cone-shaped flower-sprays which arise just above the foliage in summer are, in their daintiness and keen, clear blue, quite what one would expect in a Speedwell of such refinement. I have not found this choice species tender, despite the fact that it comes from Palestine, but although I fancy it is grateful for a sheltering pane of glass in winter, the self-sown seedlings it produces emphatically disdain such swaddlings.

V. satureioides is not with me the fat and luscious thing it is in some gardens. Still, it is vigorous enough for its area and, as if conscious of the virtues of restraint, weaves its ropy network of clinging branches over and around its buried rock and is content. These ground-hugging growths are but sparsely provided with the dark green, leathery leaves, and for several weeks in the early summer the mound bristles with erect, rather dumpy flower spikes two inches or so long. If the blooms bear some resemblance to those of the lovely V. saxatilis (V. fruticans ?), as do the leaves; they are of a more sober colour, a heavy, sullen violet which, however, can be very telling against, for instance, the milk-white of Iberis saxatilis. Indestructible hardiness and perennial vitality are attributes that none can wrest from this gentle Dalmatian, and its inflorescences outlive those of V. saxatilis by several weeks.

There is no happier plant in this garden than V. repens. If its perfectly prostrate mats of vivid, shining green may not infrequently contend for place and power with that other little Corsican, Mentha Requienii, it never seriously offends by aggressive trespass. Delighting in a cool soil, it will crop-up even in the bog and, grateful for any spot it may call its own, will sheet its refreshing verdure with the starch-white, almost stemless, wide-eyed flowers. This, with Anagallis tenella and the above-mentioned Mint, weaves a charming carpet over a waterside bed containing Gentian Pneumonanthe, Parnassias and hardy Sarracenias, incidentally checking all weeds. There is stated to be a pink form of V. repens, but this I have never been able to secure.

In a dry moraine, V. Nummularia is an attractive object, its loose trailers, set with small, round, hair-fringed, overlapping leaves of a dark green, rambling over the shingle with an easy grace. The four-lobed flowers which are borne at the tips of erect shoots, are a full-toned Speedwell-blue, soft and rich, and above the average in size. V. coriaceae is somewhat after the same style, larger in leaf and more woody, perhaps, in its flopping branches and not, I find, quite so ready with its pale blue blossoms.

No one who can resist the appeal of a quiet rose-pink in a setting of silver-grey will overlook V. caespitosa, but this Levantine species is a plant for dry, sunny positions, and one that merits the care suggested for V. telephifolia. This is a species of very special daintiness, but one worthy of much patience and the best our climate can give. Easier but bigger, yet of the same intriguing loveliness, is V. cinerea. But although this species is stated to have rose-pink flowers, I have become so accustomed to one with blue, which seems more permanent and robust, that only the voice of authority induces me to believe that this blue-flowered V. cinerea is not the type but a colour form.

The old V. pectinata one does not see so often these days, but it is a very worthy member of the mat-forming fraternity for the most meagre of soils. Its happy temperament is beyond praise, it gives us that same delightful harmony of soft pinks and blues on a background of silvery woolliness and its flowers are the largest of any trailing Speedwell I can at the moment recall. This brave old plant, which has been known to us for over a hundred years and which draped our rock gardens in the days when they were called " lapidiums " is still good enough to claim respectful attention. V. peduncularis, which is nearly as old and in some respects a still better plant, is even more uncommon.
N. Wales.

NOTICES OF BOOKS.

Garden Trees and Shrubs.

THIS book, by Mr. Walter P. Wright,* is complementary to several other books by the same author on other phases of garden work and garden plants, such as *Alpine Flowers and Rock Gardens, Roses and Rose Gardens,* and *Perennials and Herbaceous Borders.* The first edition was published in 1913, and with this second edition the opportunity has been taken of directing attention to some of the numerous new introductions of recent years. The book contains a good deal of useful information upon trees and shrubs, their cultivation and arrangement. It is written in a popular style and the author does not attempt to enter into lengthy or scientific descriptions of the many plants he mentions.

Garden Trees and Shrubs runs to 355 pages, including a good index, and there are some eighty-three illustrations and diagrams of full-page size ; twenty-four of the illustrations are in colour. The matter is divided into five parts under the headings, " The Beauty and Value of Shrubs and Trees " ; " Practical " ; " Selective," " Descriptive " ; and " Supplement." In the first part, the author is inclined to waste space on word painting, but by a little sifting it is possible to discover a good deal of Wheat among the chaff. The part dealing with practical questions will appeal most strongly to the owners of gardens, for it is in this part that questions of planting, pruning, propagation and such like matters are discussed. The information given is mostly sound, but it hardly goes far enough in some instances, for example, " The enemies of shrubs and trees " are dismissed in less than two-and-a-half pages, whereas less than a page is devoted to transplanting by means of machines. The section devoted to the selection of subjects for various positions may be profitably studied by intending planters, for the author has taken a good deal of trouble in making his selections. One, however, hardly agrees with him in describing Pinus Lambertiana as one of the hardiest of the Pines and revelling in the buffeting of the gales (see p. 71). He very properly emphasises the necessity of ample spacing. Too many people plant both trees and shrubs for immediate effect, and after a few years find that they have grown together into a dense mass, with scarcely a plant showing any individuality. Planters should try and visualise trees and shrubs at maturity when they are planting them, and space them wide enough apart to allow of proper development, then interspace with temporary plants that may be removed as occasion warrants.

In his descriptive part of the book, the author deals with a large number of trees and shrubs, giving a few words about each, and in his supplementary section he refers to new and little-known plants. The book is written for the amateur rather than for the experienced gardener or nurseryman, and the author has succeeded in producing a work that will be of considerable interest to many people.

Daffodil Growing for Pleasure and Profit.

THIS is quite the most comprehensive work on the Daffodil which has been published†; it is a mighty tome of 412 pages ! It is not the sort of book to take up like a novel and read straight off the reel. Rather is it to be regarded as a valuable work of reference, to be looked into again and again. I cannot find that the author has missed any point that would be likely to interest any lover of this Queen of Spring Flowers. There is interesting matter upon the history of the flower, and most excellent papers on hybridisation by the Rev. G. H. Engleheart, Mr. Guy L. Wilson, The Brodie of Brodie, and Mr. Herbert Chapman. Species and wild forms are dealt with by Mr. P. R. Barr, and Division XI (Various) by Mr. Herbert Longford. Progress of the Daffodil from 1890 to 1910 is from the capable pen of Mr. P. D. Williams, while the Commercial Culture of Daffodils is discussed by Messrs. F. Secrett, Abiss and Champernowne. Mr. George Monro gives a selected list of the best market Daffodils; Mr. A. M. Wilson gives a short but very valuable paper on cultivation; Mr. S. P. Wells writes of the Daffodil from many points of view, but chiefly from the commercial side, while Pests and Diseases are discussed by Messrs. Hodson and Beaumont.

---

* *Garden Trees and Shrubs*, by Walter P. Wright. Published by George Allen and Unwin, Ltd., Ruskin House, 40, Museum Street, London, W.C.1. Price 15/- net.

† *Daffodil Growing for Pleasure and Profit*, by Albert F. Calvert, F.C.S. Published by Messrs. Dulau and Co., 32, Old Bond Street. Price 21s. net.

A list of awards by the R.H.S. Narcissus Committee from 1911 to 1928 is useful for reference.

At the end of the volume will be found some two hundred photographic reproductions of Daffodil portraits, both new and old varieties. Most of these are good, some super excellent, and a few not quite good enough for such a fine book. If I may venture to criticise further on the illustrations, I would suggest that the one entitled Narcissus minor (No. 46) is not the true N. minor, but N. lobularis which is grown and sold by the Dutch growers as N. minor. The true N. minor is just like a tiny Golden Spur, with narrower foliage than N. lobularis. Again, I think N. odorus var. Campernellii (174) should be N. odorus var. rugulosus, a flower with broader perianth segments than the Campernelle Jonquil. I have discovered a few printers' errors, but that is to be expected in so large a book—what a job proof reading must have been!

On the whole, I have nothing but praise for this great effort of Mr. Calvert's, and would advise every lover and grower of the Daffodil to secure a copy if he has not already done so. I may add that the first time I sat down to write these few notes, I became so absorbed in articles by Engleheart and Guy Wilson that the total results were two or three lines at the head of the paper, which were scrapped on the following night! *J. Duncan-Pearson.*

THE CONTROL OF GREENHOUSE PESTS.

Glasshouse conditions are conducive to the rapid increase of many pests, some of which are carried in on plants and soil, while others enter by ventilators and doors. These pests present a formidable problem to the owners of large and small glasshouses alike. Spraying and hand-picking have both been tried, but fumigation has proved the quickest and most efficient means of combating the common and related pests which thrive under glass.

The most important fumigant used up to the present has been hydrocyanic acid gas. Two scientists at the Agricultural Experimental Station, Ithaca, New York, have been experimenting for the past two years on fumigants for the greenhouse, and the Cornell University recently published the results of their investigations in an interesting little pamphlet. They found that fumigation with Tobacco products, Nico-fume and Nico-fume liquid, was the safest, easiest and most efficacious method of destroying greenhouse aphides, during any time except the hottest summer weather, but that cyanide compounds, such as calcium cyanide and calcyanide, were the most effective against white flies and scale insects.

The first thing to do is to find the cubic contents of the greenhouse, and it is advisable to keep the figures handy for future reference. The greenhouse should then be made as air-tight as possible, all openings and crevices around pipes, doors, ventilators, etc., being filled in, as the fumes will not do their work properly unless sufficiently concentrated.

As the nicotine content of Tobacco stems and leaves is never uniform, varying with the kind of soil on which it is grown, and many other factors, the best and safest plan, according to the two scientists mentioned above, is to use some standard nicotine fumigant, the contents of which are definitely known. After many analyses, the investigators found that Nico-fume Tobacco is eminently suitable and easy to use. The 1-lb. tins of this are very handy for the small greenhouse and conservatory. Only a little powder should be purchased at a time as it deteriorates rapidly. Nico-fume liquid proved quite as satisfactory in destroying the aphides, but was more troublesome to use.

It was found that a two-and-a-half-inch flower pot, quite full of the powder (3½ ozs.), burned on a raised fine-wire screen or sieve, killed ninety-five to ninety-eight per cent. of the aphides. This proved the most economical and satisfactory method of fumigating a volume of 5,000 cubic feet, while it had not the slightest injurious effect on the plants. In a large greenhouse, the requisite amount of the powder should be divided into several small piles in different parts of the house, so that the fumes may be distributed evenly.

A quiet, cool night should be chosen for the fumigation, so that the ventilators may be kept closed until morning. Care should be taken to avoid the powder flaring up suddenly, as it may do if old and dry. When new, it is quite moist and smoulders away slowly. Nico-fumes do not damage any of the plants ordinarily grown in greenhouses, with the possible exception of Violets and Cyclamens.

Cyanide products are the most thorough in destroying white flies and scale insects, and they also destroy aphides. After several experiments, it was found that G. grade calcium cyanide, or the purer form, calcyanide, used in the proportion of ¼-oz. to each 1,000 cubic feet, was most effective in the ordinary greenhouse. If the house is old, and not air-tight, use one-third of an ounce.

Neither of these two products is as dangerous to use as the old form, sodium cyanide, which involved the use of water, acid and pots, and was always liable to be given off in a highly concentrated and very poisonous form. Nevertheless, it is well to remember that all cyanide compounds are extremely poisonous and dangerous to human life.

The effectiveness of calcium cyanide lies in each grain coming into contact with the air, and it should, therefore, be scattered very thinly and evenly, preferably from a glass tumbler with a perforated top, down the whole length of each walk. It is very important that the walks should not be too moist, and that the powder should be weighed accurately. Where delicate and tender plants are present, three-sixteenths-of-an-ounce should be tried first, and then another fumigation given with a slightly larger dose if not entirely satisfactory.

The rays of the sun, acting on plants surrounded by hydrocyanic acid gas, may injure them, so that fumigation should be carried out at dusk. It is not advisable on rainy nights, as the house should be so dry as possible at the time, and no watering should take place for a few hours afterwards. It has been found that three hours fumigation, in a tightly closed new glasshouse, has been sufficient to control certain pests, but it is better to allow fumigation to proceed throughout the night, in the average greenhouse, opening the ventilators early in the morning, and watering only when the house has been well aired. *Bio-chemist.*

HOME CORRESPONDENCE.

Cuttings planted with Fruit stones or grains of Wheat beneath them.—A French gardening proverb states that all woody cuttings will take root if struck on October 25—St. Catherine's Day—

> "*A la Sainte Catherine*
> *Tout bois prendracine,*"

so it is a very general practice among gardeners in rural districts in France to devote that day to striking cuttings. A well-known French botanist and entomologist, who is the schoolmaster of a tiny village in the high Pyrenees, is also a very keen and knowledgeable gardener. One day he came to the pension in which I was staying, and asked all the guests there if they would save the stones of all the Peaches, Apricots and Plums which they had, and give them to him. I ventured to ask him what he wanted them for, and he answered that he would save them for the cuttings he was going to take on October 25. I suppose I looked puzzled, for he went on to explain that if the stones of stone fruits are planted in firm ground and covered lightly with soil, and a cutting, either woody or herbaceous, inserted above, each one of these, the resultant plants will start life doubly healthy and vigorous. Since then, many other French gardeners have told me the same story, but they often put a grain of Wheat beneath the cutting instead of the stone. Last autumn I was telling this to a young workman who was interested in my gardening operations. "Why, that's what my mother always did," he told me, "She put a grain of Wheat under all the cuttings she took, and I well remember what wonderful plants she had. She was a Devon woman. Her father always did the same, she said." I wonder what property in the stone of the fruit and in the Wheat grain is responsible for the sturdiness of plants grown from cuttings struck above them? *Victoria Slade.*

Bees and Fruits.—This season, or rather, the year of 1929, has been filled with withering hopes and unexpected happenings. For the first time in my memory I found honey bees attacking fruits, expecially Apricots and Plums. Recently, when going to pick the remaining fruits from Apricot trees, I found several wasps, as usual, but I found a far greater number of honey bees; in some cases there were three or four in one fruit, and they were so persistent that when the fruits were removed in a basket, they followed them. I also found the same state of things among the Plums, only in this instance there were no wasps, and the Plums were not thoroughly ripe. This unusual taste on the part of bees I ascribe to the long drought we have experienced in this district, nearly everything being dried and withered in consequence. Owing to this state of things, no doubt, all flowers had a very limited supply of nectar, while many plants refused to open their blossoms at all. *C. Morris, Holme, Hunts.*

Auctioneers and Estate Agents.—May I be allowed to submit that it is, nowadays, almost a duty for persons following various professions and businesses to belong to an appropriate organisation? Election to regular professional bodies is not obtainable merely at will, and thus, membership of such is, in itself, some guarantee to the public of the member's probity and knowledge. The auctioneer and estate agent, like the solicitor, often has to handle large sums of money, either, perhaps, as the result of auction sales, or by way of deposit on purchase of real property. At the present time, it is true that any one can call himself an auctioneer and estate agent by paying a few pounds annually to the Revenue, and there is no evidence that the Government has, so far, contemplated reforming this state of affairs by the promotion or by the support of an equitable, although compulsory, Registration Bill. This *laissez-faire* attitude cannot, however, last for ever. What is true of auctioneering and estate agency is also true of architecture, accountancy and insurance. All these, and many other callings, are agitating for better control, and sometime the Government will be compelled to listen. When registration does come, insistence upon educational qualifications, so well as upon personal honesty and financial stability, will naturally follow. My Society obtained Incorporation from the Board of Trade in 1924, and it was then laid down in its "Articles of Association" that after the end of 1929 all elections would ordinarily be by examination. Therefore, it is only during the next three months that auctioneers and estate agents, surveyors, valuers and appraisers, rating officers, etc., may apply for Election on the "Practice Qualification," which means, broadly, on their professional experience instead of by the passing of semi-scholastic and semi-technical examinations. The Society has now a membership of over 2,000, is firmly founded financially, has a growing Benevolent Fund and Library, and is managed by a Council of practical men in intimate touch with the profession, which effectively pursues a thoroughly progressive policy. I shall be pleased to give further details, both of Election on the Practice Qualification, and of the examinations—the fifth annual session of which will be held next April—to any who write to me at the below-mentioned address. *John Stevenson, General Secretary, Incorporated Society of Auctioneers and Landed Property Agents, 26, Finsbury Square, E.C.2.*

MARKET FRUIT GARDEN.

The long drought was broken at last by heavy showers on the last two days of September—earlier, by the way, than was that of last year, when relief did not come until the second week of October. The question is, has the rain come soon enough to help late varieties of Apples? In some districts the fruits are dropping badly, and must be picked. In my plantations there is, so far, not an abnormal number of windfalls, in spite of a couple of not very violent gales. I intend, therefore, to carry on in the ordinary way with picking, and not to hasten the harvesting of varieties which have not yet reached maturity or attained full colour. I am not at all sure that, even now, there may not be some slight increase in size; and a quarter-of-an-inch means a good deal in the commercial value of the crop. Apples and Pears are undoubtedly very late in my district this year, and it seems worth while to run some risk in the hope of further development as a result of the rain. Cox's Orange Pippin has already attained good size, and need only hang a little longer to gain colour. Lane's Prince Albert has already been picked to prevent dropping, to which it is particularly liable. Allington Pippin always hangs well and can safely be left until last. The only real anxiety is the extremely heavy crop of Bramley's Seedling. In this case colour is of small importance, but any little increase in size is worth a good deal in these days when only the largest Apples are in demand for cooking.

Effects of the Drought.

Both trees and bushes in my plantations have withstood the drought surprisingly well, and just as successfully in grass as under cultivation. Just a few trees close to a tall shelter belt dried up completely, the leaves withering instead of assuming autumnal tints. The rest of the trees have remained green throughout. In some cases, where the crop was really too heavy, more moisture would have been beneficial by increasing size, although there has not been much to complain about. The worst effect of the drought has been the very slow colouring of Apples. This was particularly noticeable in the case of Worcester Pearmain, which, with me, often colours all round. It was necessary to pick over the trees repeatedly; and they were not stripped until nearly the end of September. This slow colouring is always a feature of dry seasons, moisture so well as sunshine being required. The misty mornings experienced towards the end of the month brought about some improvement in this respect. Another common effect of drought is the prevalence of physiological troubles, such as bitter pit and glassiness in Apples, most noticeable this season in James Grieve, Charles Ross and Rival. Two hot summers have apparently favoured American blight, which has spread to a serious extent in my plantations. The trouble is not confined to the usual patches on the older wood. In some varieties, especially Allington Pippin, the insects are festooned along the young shoots. Dusting with three per cent. nicotine powder was tried on some of the trees carrying the most valuable crops, and this certainly killed the majority of the insects. With a small hand machine it would have been impossible to treat the whole area; but the result is so good that the purchase of a larger machine will have to be considered if the attack develops badly again next year. Dusting is costly for material but economical for labour, and it does not require water, which is liable to be unobtainable for liquid spraying in a dry summer.

Heavy Marketing.

The work of packing and marketing fruits is very heavy this season, and, owing to the low prices ruling for most crops, the reward is not what it should be. Plums, however, were a very light crop, and were always in demand; yet prices were distinctly low, except right at the end, when a few Presidents did realise 7s. per box of 14 lbs., equal to 14s. per half-bushel. My best yield was of Belle de Louvain, the trees being fully loaded; and it was fortunate that there was a strong demand just when that variety was ready. The only period when there was anything like a glut of Plums was during the Czar season. This variety has been planted so widely, and is such a heavy bearer, that it is often too plentiful in the markets. The planting of Czar is still advocated, just because it is the easiest Plum to grow. Personally, I shall never plant another tree of it. What we want very badly is more dessert Plums. Victoria is the only true dessert variety which is commonly grown for market; but there is a ready sale also for ripe samples of Czar, Belle de Louvain, Pond's Seedling, and even Monarch for eating raw, although these can barely be described as being really of dessert quality. The true dessert Plums are all stated to be shy bearers. We are, therefore, badly in need of new varieties.

Apples are the heaviest crop I have ever had, and are accounting for most of the hard work of packing and marketing. Dessert Apples have sold well, and have been the bright spot of the season. Beauty of Bath, of which I sold over twenty-one tons, served me very well, as also did Worcester Pearmain. Many hard things are said about the latter; but I have not lost confidence in it, and intend to plant more of it. For weeks I have been selling the best grade at 8s. to 10s. per half-bushel box, and smaller Apples in half-sieves at 4s. to 7s., according to size. Extra large specimens in single-layer trays realised 2½d. per Apple, as they generally do. Worcester Pearmain may not be a connoisseur's Apple, but it is certainly in favour with the general public. In districts where it colours well it is undoubtedly a profitable variety. It has many virtues as a commercial Apple. It bears very regularly and is of ideal shape and appearance for packing. It is liable to scab, but puts up with any amount of spraying, so that the disease is easily controlled. Cooking Apples, on the other hand, have been a very poor trade since the very earliest were disposed of. For weeks I could not realise more than 7s. for the largest specimens packed in standard bushel boxes. Only recently did the last of Lane's Prince Albert make 10s. It is to be hoped that this means that the trade for cooking varieties is improving, for there are tons of Bramley's Seedling and Newton Wonder to be dealt with.

Frost and Spray Injury.

The severe frosts of February did more harm in my plantations than appeared at the time. The bark was then seen to be split on the stems of a few trees. Later on a good many more were noticed with the bark killed all down one side of the stem, but not split. During the summer the bark in some of these cases has died right round the stem, so that the trees are doomed and must be sacrificed. Bramley's Seedling is one of the varieties most commonly affected. This variety, which we used to think so hardy, is turning out to be delicate in several ways. Frost is responsible also for some of the cracking and roughness of skin in a proportion of the Apples; but I have to admit, after all, that still more of this is due to spraying with Bordeaux mixture just before blossoming. I have had some suspicion about this for several years, but this season, when the Bordeaux mixture was made with hydrated lime instead of freshly-slaked lime, there is no doubt about it. The injury is worst where spraying was done latest. The varieties most affected are Beauty of Bath, Cox's Orange Pippin, Norfolk Beauty and Lane's Prince Albert. I am loth to abandon my programme of Bordeaux mixture just before blossoming and lime-sulphur twice afterwards, as it has given almost 100 per cent. control of scab; but an alteration will have to be made. Next year I shall probably apply the Bordeaux mixture earlier, at the green cluster or "mouse-ear" stage of the buds, and follow with lime-sulphur at one part in forty at the pink bud stage, and with one or two sprayings of more dilute lime-sulphur after the fall of the petals. A good many growers are now adopting earlier spraying against scab, and there is evidence that it is necessary in order to make sure of a good control of the disease in any year. In some seasons the scab is not distributed early in the spring, and then the earliest applications are wasted. In other seasons the disease is active long before the pink bud stage, and then the early work is very valuable. I do not doubt that the hydrated lime formula for Bordeaux mixture, which is a great convenience, will be quite harmless for early use; but it is not safe so late as the pink bud stage. *Market Grower.*

THE STRAWBERRY RED SPIDER.

In view of the prevalence of the Strawberry Red Spider (Tetranychus telarius, L.) in many parts of the country this summer, it is of interest to record a few observations relating to this mite.

The Strawberry red spider is the same species as that which occurs under glass and often causes so much damage to the Tomato, the Cucumber, and other plants of the greenhouse.

Although the red spider lives and feeds upon the Strawberry for the greater part of the year, it is not noticeable to the casual observer until the latter part of July or August. This is easily explained. During May and June the mites are scattered on the under surfaces of the leaves and among the fine hairs on the stems. Greenish white eggs are present on the foliage also, usually around the veins and on the unopened leaflets. Frequently less than a dozen red spiders are to be found on any one leaf during these months. In addition, the red spiders are not red in colour at this period of the year. They are either a dirty yellowish colour, of a greenhish hue, or may be yellow with darker markings upon their backs. There are two dark spots on the back near the head.

In some years the red spider may occur in considerable numbers upon Strawberry plants during May and June, but this has not been general this season.

In July, especially during the latter part of the month, red spiders increased very considerably in number and could be seen quite easily with the naked eye on the under surfaces of the leaves The mites, their cast-off skins and eggs, literally covered the lower surfaces of many of the leaves.

The red spiders bred very rapidly all through August and during the first week of September.

The mites feed by piercing the leaves with their mouth parts and sucking out the juices from the tissues. When the mites have been feeding continuously for some time, the effect upon the plant becomes evident; the young green leaves tend to lose their fresh colour and the older foliage turns brown and dries out prematurely. Whether this damage is of economic importance or not remains to be proved.

A very severe infestation does not necessarily occur at the same time in different parts of the country. For example, red spider appeared to be causing most damage to the plants during the first and second weeks of August in many parts of Kent, while in a Strawberry-growing district near Cambridge the worst damage was noted during the last week of August and in September.

In the Maidstone district comparatively few red spiders were found upon the plants during the first week of September. Many cast skins were observed on the leaves, and a few eggs and immature mites were present also.

The absence at this time of many of the adult mites from the Strawberry plants may be explained as follows:—In September the mites prepare to go into hibernation. When ready to hibernate they become brick-red in colour.

The mites hibernate in various situations, but usually choose a place in the vicinity of the Strawberry plants. They may be found in little colonies among the dead leaves and under stones and clods of earth. In addition, they may be found in numbers inside pieces of straw that have been placed around the plants to protect the fruits earlier in the year. Some of the red spiders remain on the plants all the winter, and these are found frequently in the crowns or other sheltered places.

The mites hibernate in this manner until the following spring.

It would appear that the Strawberry red spider is of considerable economic importance, especially in a dry season such as the present one, and it would be of interest to know whether this mite is connected in any way with one or more of the Strawberry diseases that are so troublesome at the present time. *A. M. Massee, East Malling.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)
(*Continued from p.* 288.)

WALES.

Cardiganshire.—All the fruit trees flowered very freely in this district and have fruited well, with the exception of Apples, which dropped very considerably owing to the drought. Strawberries were very good. The following varieties of cooking Apples have good crops: King's Acre Bountiful, Bramley's Seedling, Lady Henniker, Annie Elizabeth and Newton Wonder. Well-cropped dessert varieties include Langley Pippin, Gascoyne's Scarlet, Beauty of Bath, Cox's Orange Pippin, Gladstone, Allington Pippin and King of the Pippins. The best Pears are Fertility, Williams's Bon Chrêtien, Souvenir du Congrés, Doyenné du Comice, Pitmaston Duchess, Conference and Clapp's Favourite, while Plums which have fruited well are Czar, Monarch, Victoria, Pond's Seedling and Transparent Gage. The soil here is cold and wet, overlying slaty rock. *W. Phillips, Derry Ormond Gardens, Llangbi.*

Carmarthenshire. — The fruit crops in general have been very good, especially Raspberries, Black, Red and White Currants, and Gooseberries. I have not grown Strawberries for the past two seasons owing to the prevalence of mildew, but I have put down a new bed this season. The Apple and Pear crops are very good, although many fruits fell owing to the drought. The soil here is light for a depth of about two feet six inches, and overlies clay. *W. Robinson, Golden Grove Gardens, R.S.O.*

Carnarvonshire. — Strawberries were the worst on record, the only variety which produced fruits of any value being Givon's Late Prolific. The severe winter killed a great number of the plants outright, and then the drought played havoc with the remainder. Our soil is very light, over a gravelly subsoil, therefore the effects of drought soon become apparent. Taken as a whole, the fruit crops generally are a good average, and the quality is good. *J. S. Higgins, Glynllivon Gardens, Llanwnda.*

Denbighshire.—Owing to the very severe winter, fruit trees in general benefited much by the long rest, and a fine show of blossom resulted, but owing to the very dry weather and cold nights, Apples and Pears failed to set heavy crops. Peaches, Nectarines and Cherries cropped abundantly, and all small fruits, with the exception of Raspberries, carried very heavy crops. The canes of the Raspberries suffered badly during the very severe frosts, in fact, many were rendered useless. Strawberry plants, although appearing practically dead with the bad spell of weather, fruited exceedingly well. *R. H. Crockford, Horsley Hall Gardens, Gresford.*

——It is very pleasing to report another average crop of fruits, Plums being the only failure. Some varieties of Apples are carrying very heavy crops, notably Lane's Prince Albert, Red Victoria, Bramley's Seedling and Lord Derby. Bush fruits cropped well, as also did Strawberries. The soil here is rather heavy, overlying marl. *J. A. Jones, Chirk Castle Gardens, Chirk, Wrexham.*

——Considering the cold spring, fruit crops have been much better than was expected. Apples are very patchy, some trees bearing average crops, while others have none. Bush and stone fruits carried average crops, although the drought adversely affected the quality of the fruits. *F. C. Puddle, Bodnant Gardens, Tal-y-Cafn.*

Flintshire.—Apples are a very good crop, with the exception of Bramley's Seedling and Newton Wonder, which were damaged in the pink bud stage by frost. Pears are a disappointment as they promised so well, but frosts damaged the blooms, and even the fruits after they were set. Plums were patchy, good to very good in places, but bad in others; on the whole, there was an average crop. Cherries were under average, but the quality of the fruits was good. Peaches and Nectarines were a very good crop; better than we have had for some years, and where watering was done the quality of the fruits was very good. Small fruits generally were not up to the average, frost damage and drought causing a good deal of fruit dropping. Strawberries were not quite up to the average as frost damaged the first flowers, but the quality of the fruits was good. Nuts are a good average crop. *Harry L. Jones, N.D.H., Padeswood Hall Horticultural Centre, near Mold.*

Glamorganshire.—In this district there has been a good general crop of fruits. Very little damage was done by frosts, but a quantity of Apples and Pears dropped owing to overcropping and also dryness of the soil in the case of recently planted and transplanted trees. It is noticeable that some Apples that bore heavy crops last season, particularly Newton Wonder, are scantily laden this year. Gooseberries were plentiful, and Raspberries, Strawberries and Currants also have carried good crops of sound fruits. The soil here is rather light loam, overlying limestone. *W. E. Wright, Tregarth Gardens, Creigian, near Cardiff.*

—— All fruit trees blossomed well, but much damage was done by cold south-east winds, especially to large exposed trees, most of whose fruits are on the protected side. Cordon Pears on walls have good crops of clean, well-formed fruits. The fruit crops, on the whole, are satisfactory. *Robert Carter, Miskin Manor Gardens, Pontyclen.*

(*To be concluded*).

VEGETABLE GARDEN.

CONCERNING ONIONS.

Often when flower-heads are developed on Onions they are simply broken off, leaving the hollow of the stem open; often, too, this is not done until the blossoms are almost appearing. It is far better to use the knife and cut off in the solid tissue, just below the bud; and the earlier this amputation is performed the better, whether the patient be Onion or Shallot.

About a year ago, my gardener came elated with tidings of the only true and certain mode of preventing bolting—it was to remove much of the roots when transplanting, a routine performance, according to some French writers. The practice was essayed, with the result that about three of every seven plants bolted, thus hardly confirming the validity of the mode and contrasting with the neighbouring bulbil-raised plants of which only some three bolted in three ten-yard rows. For many years the bulbil method has uniformly done better here than the transplantation of August sowings.

Several varieties have been tried (Brown Globe, Long Keeping, etc.), but the classic Jaune de Mulhouse seems to take a deal of beating for the purpose. The seeds are thickly sown—a patch of two feet square suffices to raise some hundreds—and the poorest patch of gravelly soil is selected; cautious hand-weeding is indicated; if raised before the green withers little trouble is needed to find the tiny bulbs; these we ripen in trays and store them over winter in a shed or cool greenhouse. For our soil we use bulbs of about five to eight millimetres, say about a quarter-of-an-inch, larger ones being rejected; in some soils those up to three-eighths-of-an-inch may be usable, therefore an experiment of different sizes may be made as a guide. Set them out in some open weather, in February, or thereabouts, but in the ridges between drills and completely buried (the same as for Shallots), for if not well rooted before they grow, the thrushes, blackbirds, etc., will pull them up; later rake away the soil to expose the bulbs. There would seem to be some economy in seeds in this practice, less labour and little or no loss from bolters.

The Tree Onion (otherwise Egyptian Onion, and its congener the American Catawissa) seems to have come from China (D. Bois), where it was described at the end of the fourteenth century. When cultivated in the orthodox way, the reward is comparatively disappointing in amount, and it is not very commonly grown. By the rubric, we plant out the bulbils in the spring and are to get a crop of bulbs which should not rush into bulbil-apology-for-blossom until the next year; its harvesting is contemporaneous with other Onions. Be this method as it may, a variant makes it bridge a gap usefully.

There often comes a time when the stored Onions are finished in the spring and the new are not yet ready for pulling. In this instance of time the Tree Onion may be made quite useful. Plant the little bulbs in autumn (best, perhaps, in September), probably with the precaution against birds, given above. They soon push out and grow more or less all the winter, so that when spring comes they lightly turn to thoughts of bulb-making; if this is allowed to happen, the "Leek-like growths" of some inch or so in diameter, will rapidly become woody and fibrous, in fact, they are heartily spurned from the kitchen. If, however, their blossoming is stopped by cutting off the summits so soon as they are recognised, quite a useful set of long, Leek-like, cylindrical Onions are available for the kitchen, probably until "Onions come again." Thus one may bridge over the lacuna between old and new—a matter sometimes of importance.

There seems to be some error in D. Bois (*Les Plantes Alimentaires*, to be considered the fourth edition of the indispensable *Potager d'un Curieux*), for he puts it as Ail Rocambole (Allium Scorodoprasum), which as a Garlic sort should have flat leaves. Vilmorin leaves us uncertain, for his description is vague, and what we grow as Rocambole has Garlic-like leaves, although it does not make bulbils instead of blossoms.

We also grow a strain of Leek which has a habit of making, mostly, flowers at its head, but these are mixed with a variable proportion of bulbils, not, however, on every head. It had a Balkan origin. These bulbils are quite minute, and could hardly be utilised for pickles as may those of the Tree Onion. *H. E. Durham.*

FOREIGN CORRESPONDENCE.

HETEROSIS.

The interesting remarks on the above in your issue for June 22, 1929 (Vol. LXXXV, p. 455), reminds me that, apart from Maize, there is another subject that comes under the same heading, although as a rule, true varietal stocks of it may, and generally are, raised from seeds. If you consult the current season's catalogue of Ernst Benary, Erfurt, you will note, among the novelties, a Tomato he calls Heterosis. This novelty differs from the general type, in that it will not breed true from its seeds, so that the same cross has to be made year after year in order to secure it. What the parentage is, Mr. Benary does not state. He claims that it is extraordinarily vigorous, resembling the variety Lucullus, but much earlier both indoors and outside. It is a tremendous cropper, and it is claimed it will out-yield any other variety by twenty to twenty-five per cent.

It is of interest to note, too, that the Benary Begonias Prima Donna, Broadcast, Bonfire, Pink Perfection, Erfordia and Glory of Erfurt, are heterozygous varieties, and cannot be raised true from selfed seeds. *T. A. W., New Jersey.*

SOCIETIES.

ROYAL HORTICULTURAL.

The Fruit Show.

(*Concluded from p.* 294.)

Single Dish Classes: Apples.

The classes for single dishes of specified dessert and cooking Apples provided a capital display of grand fruits, and in the majority of the classes the number of entries was very gratifying and competition was keen.

For a dish of Adams's Pearmain, W. P. Metcalfe, Esq. (gr. Mr. C. A. Fane), Stone Hall, Oxted, was first, and this exhibitor also showed the best Claygate Pearmain. Twenty-three dishes of Allington Pippin were shown, the fruits exhibited by F. J. Long, Esq., The Moorings, Belmont, being adjudged the best; as also were his fruits in the popular class for Cox's Orange Pippin, thirty-one dishes of which were entered.

W. J. H. Whittall, Esq. (gr. Mr. J. M. Grant), Grayswood Hill, Haslemere, was first for American Mother, and for King of the Pippins, showing grand fruits of each; while of the twelve dishes of Blenheim Pippin, that staged by Mr. C. Butt, High Park, Isle of Wight, was considered the best. Mr. A. L. Linfield, The Homestead, Old Bletchley, was first in the popular class for Charles Ross; Mrs. J. J. Barrow (gr. Mr. H. E. Kemp), Holmewood, Langton, was first for Duke of Devonshire; while Mr. J. A. Stidston, Bishopsteignton, led for Egremont Russet.

Mr. A. H. Pullen, Hawthorne Road, Wallington, was a good first in the class for Ellison's Orange, and was also first for James Grieve, showing excellent fruits of both; while Mr. E. G. Hunt, Fremington, Barnstaple, showed the best dishes of King's Acre Pippin and Superb. Mr. E. Reynolds, The Avenue, Watford, was first for Orleans Reinette.

There were nineteen excellent dishes of Ribston Pippin shown, Mr. F. J. Long being awarded the first prize; while Mr. J. A. Stidston scored with Rival, and was also first for St. Cecilia. W. J. H. Whittall, Esq., exhibited the best dish of Sturmer Pippin, and was also first for a dish of any late dessert variety not included in the specified variety classes, showing good fruits of Golden Russet.

The best dish of William Crump was that exhibited by R. J. Corbett, Esq. (gr. Mr. J. Jones), Ymp-y-Maengwyn, Towyn; Captain J. P. Whiteley (gr. Mr. L. R. Coles), Bletchley Grange, Bletchley, was first with grand fruits in the class for a dish of an early dessert variety not included in the schedule, showing St. Edmund's Russet, while Mr. E. G. Hunt was first for any dessert Apple not offered for sale before 1919.

In the section for single dishes of cooking Apples, J. H. London, Esq. (gr. Mr. J. Bond), Olantigh, Wye, was first for Annie Elizabeth, while of the twelve exhibits of Bismarck, that entered by W. J. H. Whittall, Esq., was awarded the first prize. The last named exhibitor also led for Blenheim Pippin (large fruits), for Encore, and for Gascoyne's Scarlet.

The Earl of Sandwich (gr. Mr. W. J. Prowting), Hinchingbrooke, Huntingdon, showed grand fruits of Bramley's Seedling, and was awarded the first prize in this popular class; C. G. A. Nix, Esq. (gr. Mr. E. Neal), Tilgate, Crawley, was first for Crawley Beauty, and Miss M. Gardner (gr. Mr. G. Sturt), Oakhurst, Harrow, led for Dumelow's Seedling. Viscount Hambledon (gr. Mr. W. Turnham), Greenlands, Henley, scored a success with Edward VII, while the Earl of Bessborough (gr. Mr. T. A. Tomalin), Stansted Park, Emsworth, Sussex, was first for Golden Noble; for Warner's King, and for any variety for which there was not a special class, showing grand fruits of Loddington.

H. W. Henderson, Esq. (gr. Mr. F. L. Pike), West Woodhay, Newbury, was the first prize winner in the class for Golden Spire; and Mr. A. R. Carlisle, The Mattings, Henlow, led for Lane's Prince Albert; while Lord Waverley (gr. Mr. R. H. Crockford), Horsley Hall, Gresford, was successful with Lord Derby, in splendid condition.

Mr. J. A. Stidston was the only exhibitor in the class for Monarch, and he was awarded the first prize; W. J. H. Whittall, Esq., exhibited the best dish of Newton Wonder; and Mr. A. J. Smith, The Yews, Bengeo, Hertfordshire, was first for Peasgood's Nonesuch, with fruits of excellent quality. Mr. J. A. Stidston scored another success in the class for a dish of The Queen, while Mr. E. G. Hunt showed the best fruits of Rev. W. Wilks. J. Caird, Esq. (gr. Mr. F. Moon), Wimbledon Park, showed the prize-winning dish of Stirling Castle.

Single Dish Classes: Pears.

As in the single dish classes for Apples a high standard of quality and keen competition were evidenced in the various classes for single dishes of varieties of dessert Pears.

Mr. A. H. Pullen was first for Buerré Bosc, and Major C. H. Drummond (gr. Mr. L. A. Smith), Cadland Park, Southampton, was awarded the first prize for Beurré d'Anjou; for Glou Morceau, and for Louise Bonne of Jersey, the latter being a very popular class, with twenty-two entries.

There were fourteen exhibits in the class for Beurré Hardy, and many grand fruits of this popular variety were shown, the best being those from H. F. Baker, Esq. (gr. Mr. J. Lovell), Red Roof, Broom Road, Teddington; this exhibitor also scored with Winter Nelis. The Earl of Sandwich was first for Beurré Superfin, and H. L. Hornby Lewis, Esq. (gr. Mr. A. E. Friend), Danesfield Park, Marlow, showed the best Comte de Lamy. R. J. Corbett, Esq., was first for Conference, there being seventeen entrants in this class; while Lord Suffield (gr. Mr. A. J. Jones), Gunton Park, Norwich, was awarded the first prize for his dish of Doyenné du Comice; for Marie Louise, and for a dish of an early variety not included in the special class list, showing good fruits of Triomphe de Vienne.

W. P. Metcalfe, Esq., was the first prize-winner in the class for Durondeau; H. W. Henderson, Esq., showed the best Easter Beurré; Lady Mary Morrison (gr. Mr. W. H. Mills), Fonthill House, Tisbury, was first for Emile d'Heyst, and the Hon. Henry Coventry (gr. Mr. J. G. Jackson), Tendsing Hall, Stoke-by-Wayland, scored with Fondante d'Automne.

For a single dish of Joséphine de Malines, Lt.-Col. F. J. B. Wingfield Digby (gr. Mr. E. Hill), Sherborne Castle, Dorset, was awarded the first prize; E. H. Sikes, Esq. (gr. Mr. G. Diggens), Freyerning Grange, Ingatestone, showed the best Marguerite Marillat and Viscount Hambledon was first for Pitmaston Duchess.

In the class for a dish of Thompson's Pear, Mrs. Winterbottam (gr. Mr. G. Brown), Oakley Place, East Grinstead, showed the first prize set, while the Duke of Newcastle showed the best of the twenty-two dishes entered in the class for a dish of any late variety not included in the special class list, his variety being Charles Ernest. J. H. London, Esq., showed, in Triomphe de Vienne, the best-flavoured Pear not included in the single dish classes.

Special District Classes.

The classes confined to special districts, for fruits grown in the open, as usual proved very interesting, although some of the classified areas were but poorly represented.

Two classes were allotted to each district, one being for six varieties of Apples, four cooking and two dessert, and the other for six varieties of dessert Pears, one dish of each variety in each class.

In the classes open only to growers in Kent, Surrey, Sussex and Hampshire, no first prize was awarded for Apples, the second prize going to the Earl of Bessborough who, however, was first for Pears.

Lady Mary Morrison showed the best set of Apples in the class confined to Wiltshire, Dorsetshire, Somersetshire, Devonshire and Cornwall, her varieties being Cox's Orange Pippin, Herring's Pippin, Lord Derby, Ribston Pippin, Bramley's Seedling and Warner's King, and she was also first for Pears, showing excellent fruits of Marguerite Marillat, Beurré Hardy, Conference, Durondeau, Pitmaston Duchess, and Doyenné du Comice.

In the classes limited to growers in Oxfordshire, Buckinghamshire, Bedfordshire, Berkshire, Hertfordshire and Middlesex, A. R. Carlisle, Esq., was first for Apples, his varieties being Mère de Ménage, Newton Wonder, Cox's Orange Pippin, Rival, Cox's Pomona and Lane's Prince Albert; while Brigadier R. G. H. Howard-Vyse (gr. Mr. F. S. Cook), Stoke Place, Slough, was first for Pears.

Splendid fruits of Ribston Pippin, Superb, Gascoyne's Scarlet, Newton Wonder, Lane's Prince Albert and Bramley's Seedling secured for the Earl of Sandwich the first prize for Apples in the class confined to growers in Essex, Suffolk, Norfolk, Cambridgeshire, Huntingdonshire and Rutland; no first prize was awarded for Pears, but the Earl of Sandwich secured the second prize.

In the classes for growers in Lincolnshire, Northamptonshire, Warwickshire, Leicestershire, Nottinghamshire, Derbyshire, Staffordshire, Shropshire and Cheshire, the Earl of Ancaster (gr. Mr. F. J. Foster), Grimthorpe Castle, Bourne, was first for Apples, his best fruits being of Peasgood's Nonesuch, Allington Pippin and Bramley's Seedling, the first prize for Pears going to the Duke of Newcastle (gr. Mr. S. Barker), Clumber, Worksop, who had grand fruits of Marguerite Marillat, Pitmaston Duchess, Doyenné du Comice, Charles Ernest, Le Lectier and Conference.

The Earl of Coventry (gr. Mr. W. H. Wilson), Croome Court, Severn Stoke, Worcester, was first for Apples in the Gloucestershire, Worcestershire, Herefordshire and Monmouthshire class, with good dishes of Lady Henniker, Mère de Ménage, Newton Wonder, Blenheim Pippin, King of the Pippins and Ribston Pippin, the first prize for Pears being secured by Mrs. D. J. Mitchell (gr. Mr. A. W. Neal), Winchcombe. With a set which contained specially good fruits of Peasgood's Nonesuch and Bramley's Seedling, Captain Compton (gr. Mr. A. Mason), Newby Hall, Ripon, secured the first prize for Apples in the six northern counties and Isle of Man class, and Lord Hotham (gr. Mr. J. S. Coates), Dalton Hall, Beverley, was first for Pears. Lord Wavertree was first for both Apples and Pears in the classes for Welsh growers, his Apples being grand examples of Ribston Pippin, Mère de Ménage, Cox's Orange Pippin, Peasgood's Nonesuch, Rev. W. Wilks and Bramley's Seedling; while in the classes open only to growers in Scotland, Major E. L. Gordon (gr. Mr. J. Duff), Threave Castle, Douglas, led for Apples, his fruits of Rosebery and Ben's Red being of wonderful colouring; there were no exhibits of Pears.

The Earl of Bessborough (gr. Mr. T. E. Tomalin), Bessborough, Piltown, Kilkenny, was the only exhibitor of Apples in the Irish classes, and he was awarded the first prize, his fruits of Yorkshire Beauty, Hambling's Seedling and Royal Jubilee being very fine; the Earl of Bessborough was also first in the corresponding class for Pears. There were no entrants for the Channel Island classes.

Affiliated Societies Competition.

The Challenge Cup Competition, open to Societies affiliated to the R.H.S., provided one of the most attractive features of the Show. A collection of eighteen dishes of Apples and Pears (six varieties of dessert Apples, six of cooking Apples, and six of dessert Pears) was required, all of the fruits to have been grown out-of-doors, and by members of the Society staging the exhibit. Six grand collections of fruits were staged.

The Pangbourne and District Gardeners' Mutual Improvement Society was awarded the Challenge Cup and Silver-Gilt Hogg Medal for a superb collection, which included grand sets of Apples Peasgood's Nonesuch, Bramley's Seedling, Cox's Orange Pippin, James Grieve, and Ribston Pippin, and Pears Conference, Beurré Hardy, Pitmaston Duchess, Doyenné du Comice, Le Lectier and Souvenir du Congrés.

Non-Competitive Exhibits.

These assisted greatly in making this show a success, for several very extensive trade groups of fruits were staged, together with other exhibits of educational value.

One of the most meritorious groups in the hall was that set up by Mr. J. C. Allgrove, twice the size of the one he received a Gold Medal for at the previous show. Fruit trees in pots, all heavily laden with fruits, were arranged in association with baskets and dishes of numerous varieties, in an exceedingly attractive manner. Among the best of the fruit trees were the fan-trained Plums President, Pond's Seedling and Jefferson, while the baskets of Plums Coe's Golden Drop and September Prolific were excellent. The fan-trained trees of Peach Sea Eagle also were very fine, together with the pot trees of Apples S. T. Wright, Allington Pippin, and Gascoyne's Scarlet. Good dishes of Apples were of the varieties Charles Ross, Peasgood's Nonesuch, American Mother, Emperor Alexander, Belle de Boskoop, Ellison's Orange and Edward VII; while there were grand specimen fruits of Pears Beurré Hardy, Durondeau, Louise Bonne of Jersey, Doyenné du Comice, Pitmaston Duchess, Conference, and many others; Plums in baskets included excellent fruits of Wyedale, Coe's Violet and Late Orange. An excellently arranged group of first-class trees and fruits.

Messrs. George Bunyard and Co., Ltd., showed an extensive collection of Apples, Pears, Plums and other fruits, all in grand condition and in many instances richly coloured. Among Apples exhibited were Christmas Pearmain, Superb, Allington Pippin, Gascoyne's Scarlet, Ellison's Orange, Reinette Rouge Etoilée, Charles Ross, American Mother, Wealthy, Mère de Ménage, Twenty Ounce, Lady Sudeley, Smart's Prince Arthur, Withington Fillbasket and Emperor Alexander, while noteworthy among the many varieties of Pears were Pitmaston Duchess, Beurré Hardy, Beurré Diel, Glou Morceau, Marguerite Marillat, President Roosevelt, Beurré Superfin, Double de Guerre, Catillac and Doyenné du Comice. A very interesting and instructive exhibit.

Another splendid collection of fruits, attractively arranged, was that staged by Messrs. J. Cheal and Sons, Ltd., who, besides showing well-fruited specimen trees of Apple King George V, had large baskets of grand fruits of Apples Warner's King, Bismarck, Lane's Prince Albert, Arthur Turner, Herring's Pippin, King Edward VII, Charles Ross and Bramley's Seedling, and dishes of Mabbott's Pearmain, Ellison's Orange, Redcoat Grieve, Guelph, Red Wing, Rival, Forge, St. Cecilia, The Houblon and American Mother, with many others. Among their best Pears were Doyenné du Comice, Princess, Beurré Clairgeau, Beurré Bachelier, President Roosevelt, Conference, Beurré de Naghan and Glou Morceau.

Messrs. Daniels Bros. staged a small but choice collection of Apples and Pears, outstanding among the former being Herring's Pippin, Peacemaker, Lord Derby and Norfolk Beauty, while their Pears included Pitmaston Duchess, Conference, Marguerite Marillat, President Roosevelt and Louise Bonne of Jersey. They also showed branches of Black Currant Daniel's September heavily laden with trusses of fruits.

An extensive and representative collection of Apples and Pears of grand quality, was staged by Mr. R. C. Notcutt. His Apples included Rival, James Grieve, Anne Elizabeth, Allington Pippin, Duchess of Oldenburg, The Queen, Herring's Pippin, Ellison's Orange, Guelph, Blenheim Pippin, Monarch, American Mother, and Rev. W. Wilks, while among his Pears were good dishes of Winter Orange, Emile d'Heyst, Doyenné du Comice, Conference, Durondeau, Triomphe de Vienne, King Edward, Beurré Clairgeau, St. Luke, Beurré Baltet Pére, Le Brun and Pitmaston Duchess. He also showed dishes of Plums Monarch, President and Pond's Seedling.

The Barnham Nurseries, Ltd., had a good collection of Apples and Pears in baskets, the former including the varieties Red Victorian, Rival, Washington, Ben's Red, Charles Ross, Guelph, Charles Eyre, Peacemaker and Herring's Pippin; while the best of the Pears included Conference, Verulum, Souvenir du Congrés, Beurré Duboisson and St. Luke. Messrs. G. and A. Clark, Ltd., also staged a collection of many popular varieties of Apples and Pears; and Messrs. S. Spooner and Sons had grand baskets of Apples Allington Pippin, Worcester Pearmain, Hounslow Wonder, Lord Derby and Cox's Orange Pippin. Messrs. Herbert Chapman, Ltd. showed the crop of one espalier tree of Apple Saltcote Pippin, which would appear to be very free cropping, and Mr. J. J. Kettle showed autumn-fruiting Raspberries. Lovely bunches of Grapes Lady Downe's, Black Alicante, Muscat of Alexandria and Gros Colmar, in perfect condition, were exhibited by Messrs. J. Almond and Son.

Messrs. T. Rivers and Son arranged a grand group of fruit trees in pots, all very healthy and carrying good crops. They included Apples Peasgood's Nonesuch, St. Cecilia, Gascoyne's Scarlet, Wealthy, Cox's Pomona and King of Tompkin's County; Peach Salway; Plums President and Coe's Violet; and Pears Marguerite Marillat and Beurré Bedford. They also had baskets of grand specimen fruits of Apples Ribston Pippin, James Grieve, Melon, Peasgood's Nonesuch, King of Tompkin's County, Cox's Orange Pippin, Charles Ross and Washington.

Messrs. Laxton Bros. staged a group of baskets of first-class fruits of Apples and Pears surrounded by beautifully trained cordon trees of Apples and Pears. Noteworthy Apples which they showed were Lord Lambourne, Laxton's Epicure, Rival, Gascoyne's Scarlet and Laxton's Superb, while their Pears included Louise Bonné of Jersey, Marguerite Marillat, Doyenné du Comice and Beurré Bedford.

From the Royal Horticultural Society's Gardens, Wisley, came a representative collection of Apples and Pears, sixty varieties of the former and thirty-two of the latter being shown, together with vases of ornamental fruiting Pyruses, among which the Wisley Crab was notable.

The University of Reading Horticultural Department staged an educational exhibit consisting of Apples beautifully graded and packed for market; and excellent bunches of Grapes Lady Downe's, Black Alicante, Diamond Jubilee, Gros Maroc and Lady Hutt. The exhibit also contained baskets of numerous Apples and Pears, each variety being instructively labelled with the name, class, season and origin.

An interesting exhibit of growing plants of the Cape Gooseberry Gold Nugget, a basket of ripe fruits, and dishes of preserves made from them, was shown by Sir William Lawrence, Bt. (gr. Mr. W. Everatt), Burford, Dorking, while S. Brown Esq. (gr. Mr. H. Rosewell), Brownlands, Shepperton, staged an exhibit of fruits of Passiflora quadrangularis, and a magnificent bunch of fruits of Musa sapientum grown in the glasshouses at Brownlands. He also showed a fruit produced on Melon Earl's Favourite pollenated with Cucumber Carter's Improved Telegraph; the fruit was about six inches long and four-and-a-half inches through, distinctly and regularly grooved longitudinally, and dark green, mottled lighter green.

Mr. Walter Hearn, Cornerways, Spence Road, Chiswick, exhibited a small collection of Apples, and W. J. H. Whittall, Esq., showed single specimen fruits of 150 varieties of Apples grown on the greens and at Haslemere, at 600 feet above sea-level.

Vegetable Show.

The vegetable show, held in conjunction with the exhibition of fruits, was staged in the old R.H.S. hall, and although the exhibits in the competitive classes were, perhaps, not so numerous as in previous years, the general quality of the produce shown was high, and there were several grand trade exhibits.

Vegetable Collections.

The exhibits staged in the important class for a table of vegetables, ten feet by four-and-a-half feet, were extremely good. Viscount Hambledon (gr. Mr. W. Turnham), Greenlands, Henley-on-Thames, was awarded the Silver Cup and first prize, the points awarded his exhibit by the judges being:—Variety, 20 out of a possible 25; quality, 45 out of 55; and arrangement, 19 out of 20, making a total of 84 points out of a possible 100. The exhibit included orange and red Capsicums; grand Ailsa Craig Onions; white and red-stemmed Celery; Carrots New Red Intermediate and Long Red Surrey; Radishes, Runner Beans, Turnips, Potatos Red King, Catriona, Bishop, King Edward and others; Vegetable Marrows, Parsnip Tender and True; Cucumbers, Kohl Rabi Early Purple, Cabbage Lettuces, Cauliflower All the Year Round, Pea Gladstone, and others. Sir Randolf L. Baker (gr. Mr. A. E. Usher), Ranston, Blandford, was second, with 79 points, and Dr. J. A. C. Roy (gr. Mr. A. Falconer), Cheadle Royal Mental Hospital, was third, with 77 points.

In the class for a collection of twelve kinds of vegetables, one variety of each, Viscount Hambledon was again first with a grand set of Onion Ailsa Craig, Pea Gladstone, Tomato Best of All, Cucumber Everyday, Potato Arran Comrade, Beetroot Selected Black, Carrot New Red Intermediate, Runner Bean Prizewinner, Parsnip Tender and True, Celery Giant Red, Cauliflower Autumn Giant, and Leek Acquisition. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, was a good second, and Lord Riddell (gr. Mr. A. Payne), Walton Heath Golf Club, was third.

Six exhibits were staged in the class for a collection of nine kinds of vegetables, open only to amateurs who have not more than six employees in the garden, the best being that shown by Sir D. Watson, Bt. (gr. Mr. R. Macdonald), Burrswood, Groombridge, who had splendid specimens of Leek Royal Favourite, Onion Ailsa Craig, Cauliflower Michaelmas White, Carrot New Intermediate, Parsnip Tender and True, Potato Ben Lomond, Tomato Best of All, and Cucumber Delicacy. W. Robinson, Esq., Sunny Bank, Forton, Lancashire, was second; and Earl Beatty (gr. Mr. A. Barrett), Reigate Priory, Surrey, was third. C. Ward, Esq. (gr. Mr. A. G. Lane), Murrel, Ware, secured the first prize for a collection of six kinds of vegetables, with an excellent set, the Rev. F. G. Wyatt (gr. Mr. J. E. Shirley), Horley, being placed second; while in the class for six kinds of vegetables, open to those who employ a single-handed gardener only, F. Barratt, Esq., High Street, Eltham, was first and E. A. Whitlock, Esq., Alton, Hampshire, second, the former exhibitor including a grand set of Onion Premier in his collection.

Of the five collections of twelve varieties of Potatos, Viscount Hambledon's was considered the best, the dishes of Catriona, Bishop, King Edward, Di Vernon and Doon Star being outstanding; second, E. P. Dashwood, Esq., (gr. Mr. C. Fuller), Oxford; and H. W. Henderson, Esq. (gr. Mr. F. L. Pike), West Woodhay, Newbury, third. There were thirteen exhibits in the class for six varieties of Potatos immune to wart disease, the premier award being secured by Dr. J. A. C. Roy, who showed grand tubers of Edzell Blue, Bishop, Snowdrop, (Witch Hill), Mr. Breese, Sefton Wonder and Arran Comrade; second, Viscount Hambledon, with Catriona, Arran Comrade, Arran Rose, Bishop, Di Vernon and Snowdrop; third, Mr. F. Barratt.

Sir Randolf L. Baker showed the best collection of six varieties of Onions, his varieties being Gretton Globe, Ailsa Craig, Blood Red, Longkeeping, Red Globe and A.1; second, Viscount Hambledon; third, Lord Riddell. The premier award for a collection of six kinds of salad vegetables was won by Viscount Hambledon, who showed Cabbage Lettuce Ideal, Globe Beetroot, Cucumber Everyday, Tomato Best of All, Mustard, Cress, and Celery Solid White; Dr. J. A. C. Roy was second, and Lord Riddell, third.

Single Dish Classes.

In the classes for single dishes of vegetables competition throughout was keen, and produce of high quality was the general rule.

Earl Beatty was first for Runner Beans with grand pods of Prizewinner of even size and form, and Lord Riddell led for French Beans, his variety being The Prince. There were fifteen entries in the class for Beet, of the Globe type, the premier award being secured by Lady Stucley (gr. Mr. T. H. Bolton), Hartland Abbey, Devon, with fine roots of Sutton's Globe; second, Mr. M. G. Stuart, Hanwell. Mr. W. J. Cherry was first for long-rooted Beet.

Dr. J. A. C. Roy showed the best Brussels Sprouts, his dish being of medium-sized buttons of the variety Exhibition, other successes scored by the Cheadle produce being first prizes for Celeriac, Peas, Turnips, white-fleshed and also yellow-fleshed Turnips. Sir W, Lawrence, Bart., was first for Cabbages, with good specimens of Goliath; Mr. W. Robinson led for Cauliflowers, with lovely heads of Autumn Giant; the Rev. L. G. Wyatt secured the first prize for white Celery, and E. P. Dashwood, Esq. (gr. Mr. C. Fuller), Aston Rowant, Oxford, was first for red Celery.

Other first prize-winners in the single dish classes were A. D. Sanderson, Esq. (gr. Mr. A. E. Adlam), Selsdon Park Hotel, Sanderstead, for Cucumbers; Viscount Hambledon, for Leeks, Onions and kidney-shaped Potatos; Mr. A. C. Britten, 82, Glanthorne Road, London, N., for Marrows; G. Meyer, Esq. (gr. Mr. R. Cottam), Wistler's Wood, Woldingham, for Mushrooms; E. P. Dashwood, Esq., for Parsnips and round Potatos; S. Wallrock, Esq., for long or intermediate Carrots, and for any vegetable for which there was no special class, showing good specimens of Savoy Best of All; Earl Beatty, for stump-rooted or short Carrots; Sir Randolf L. Baker, for red Tomatos; and R. Chetwynd Stapylton, Esq., (gr. Mr. W. Meagen), Headland, Berkhamsted, for yellow Tomatos.

Non-Competitive Exhibits.

A spectacular, highly educational and very extensive group of vegetables was staged by Messrs. Sutton and Sons, all the produce displayed being in perfect condition. They showed lovely heads of Cauliflowers Early Giant, Autumn Giant, Autumn Mammoth, and All the Year Round; golden and red-fruited Capsicums; Celery Solid White, Superb Pink and Sulham Prize; Leeks Acquisition and Prizetaker; giant Cardoon Large Solid; Chilis, Aubergines, Globe Artichokes, Onions Ailsa Craig, The Sutton Globe, Long-keeping, White Leviathan, Park Hero, Crimson Globe, and others; Gourds in variety; Khol Rabi; red and yellow-fruited Tomatos; Cucumbers, Vegetable Marrows, Potatos in numerous sorts, and a host of other subjects. The whole made a magnificent display.

Messrs. Dobbie and Co., Ltd., staged one of their famous exhibits of Potatos, outstanding among their numerous varieties being Edzell Blue, Arran Crest, Mien's Early Round, Dunbar Cavalier, described as an immune King Edward; Quarantine Rosa and Quarantine Violette, two Potatos of French origin; Arran Banner, Arran Chief, Arran Comrade, Climax, Di Vernon, Herald, Kerr's Pink, Midlothian Early, Mr. Breese, Red King and The Ally.

This firm also set up an interesting exhibit (Fig. 143) consisting of seed heads of various vegetables grown on the firms seed farm in Essex, among the vegetables represented being Spinach, Carrot, Kale, Beet, Onions, Leeks, Peas and Beans, various Brassicas, Celery, Parsley, Turnip and Marrow.

In the interesting vegetable collection staged by Messrs. Barr and Sons we noted grand heads of Cauliflowers Best of All, Autumn Mammoth and All the Year Round; Celery Solid Pink and Solid White; Lettuce and Endive in variety; Onions of various types; Shallots, Tomatos, many varieties of Potatos, Maize, Jerusalem and Globe Artichokes; Cucumbers, Vegetable and Custard Marrows; Leeks Giant Winter and Prizetaker; Carrots, Turnips and several other vegetables and salads, the whole making a very praiseworthy exhibit.

Several floral exhibits were staged in the old hall. Dahlias were shown by Messrs. J. Cheal and Sons, Ltd., Messrs. H. Langridge and Co., Mr. J. B. Riding and Mr. J. T. West; Chrysanthemums by Mr. J. W. Forsyth; and Michaelmas Daisies by Mr. T. Bones, and the Gay Border Nurseries. Messrs. W. Wood and Son, Ltd., set up a mixed group of Dahlias and perennial Asters.

ISLE OF WIGHT HORTICULTURAL.

The above Association holds three exhibitions during the year, one in July, another in October, and a Chrysanthemum exhibition in November, and all of these are invariably popular.

The autumn show was held at the Drill Hall, Newport, on October 3, 4 and 5, and the result was a splendid exhibition of flowers and fruits, the vegetables, owing to the long drought, not being up to the usual high standard.

The Silver Challenge Cup presented by the President, Lady Seeley, for a collection in a space on stagihg not exceeding ten feet by four feet six inches, was won by the Gatecombe and Carisbrooke Horticultural Society, with a creditable display; while in the same section, for affiliated societies, the best group on a space six feet by four feet six inches was staged by the Sea View Horticultural Society.

For a collection of fruits—Apples and Pears—Mr. C. Butt, Ryde, was first; Mr. C. Bound, Norton, second; and General Leveson-Gower (gr. Mr. A. Baker), third. Some remarkably highly coloured Apples and fine Pears were shown in these collections. Prizes for graded Apples, packed ready for market, were won by Mr. G. Russell, Ryde.

The single dishes of Apples and Pears were very fine, Mr. Butt and Mr. Russell being the chief prize-winners.

The display of twelve Onions on trays was an outstanding feature; there were six competitors, and the winner was Mrs. Parsons (gr. Mr. W. Birch), Shanklin; second, Lt.-Col. Brent Good (gr. Mr. S. Jones), Norton. All showed fine specimens of Ailsa Craig, spring-sown.

The collections, of vegetables in trays, from scholars in elementary schools, created much interest, some creditable produce being shown. There were six lady competitors in the table decoration class, Mrs. W. H. Dove being placed first, with an arrangement of Rose Ivy May, and Miss Dove second.

The trade exhibits made a great display. The large and beautifully arranged collection of every section of Dahlias by Messrs. J. Cheal and Son, Crawley, was of outstanding merit. Mr. E. C. Goble, Ryde, had a smaller collection, and Mr. W. H. Dove, Newport, had a fine bank of early-flowering Chrysanthemums. Mr. Frank Barwell, Alverstone Nurseries, showed eighty baskets of distinct varieties of Apples. Rev. A. Dedemas, Yarmouth, staged an interesting collection of new and old varieties of Apples.

ROYAL CALEDONIAN HORTICULTURAL.

At the monthly meeting held at Edinburgh on October 1, Mr. George E. Greenhowe, Marischal College, Aberdeen, delivered a lecture on "Trials of Varieties of Black Currants in the North of Scotland." He showed, by means of lantern slides the chief distinctive characteristics of the different varieties, most of which were included in the East Malling classification, and specified Edina as the best in the trials, so far as weight of crop and freedom from big bud was concerned.

In the following table, the cropping results are shown, the figures in each relating to the average yield per bushel:—Edina, 11 lbs. 11 ozs.; Victoria, 10 lbs. 6 ozs.; Seabrook's Black, 8 lbs. 4 ozs.; French Black, 8 lbs. 1 oz.; Baldwin, 6 lbs. 6 oz.; and Boskoop Giant, 5 lbs. 2 ozs. Calculated at the rate per acre, the yield was as follows:—Edina, six tons; Victoria, 5¼; Seabrook's Black, 4⅛; French Black, 4; Baldwin, 3; and Boskoop Giant, 2¾. The lecturer stated he knew a grower in Morayshire who took 2¼ tons of fruits from half-an-acre planted with Black Currants, and a railway porter who made £30 from one-eighth-of-an-acre in his garden.

The Chairman, Mr. Robert Scarlett, did not think it possible to raise five tons to the acre, and said if growers got two-and-a-half tons they did very well.

Exhibits of Michaelmas Daisies by Messrs. Dobbie and Co., Ltd., and of Begonias varieties Optima and Elatior, by Messrs. Wilson and Co., were awarded Gold Medals.

In the competitive section, Mr. R. B. White was first for a vase of Chrysanthemums (Dick Barnes), and for four Carrots.

DERBYSHIRE HORTICULTURAL.

The first monthly meeting of the Derbyshire Horticultural Association was held in St. James's Hall, Derby, on September 30, when Mr. J. Woolman, of Birmingham, gave a lecture upon the cultivation of Chrysanthemums before a large gathering of members.

Mr. Woolman began his lecture with a brief history of the Chrysanthemum, and he stated it was not until the year 1764 that the first plant was brought from Japan. For centuries the Chrysanthemum has been held in high favour in both China and Japan, and it was a Mikado of Japan who instituted the Order of the Chrysanthemum as one of the highest Orders he could bestow. A Mr. Wheeler, of Oxford, was the first Englishman to grow Chrysanthemums successfully in this country, and this was about 1830. The first show is stated to have taken place in Norwich in that year, and the second in Birmingham in 1836, for plants. Stoke Newington was the first to hold an exhibition for cut blooms, and is stated to be the parent of the present National Chrysanthemum Society.

The treatment of plants from the time of taking the cuttings in November, December and January, through the various pottings in suitable composts, the stopping and timing, feeding, housing, watering and remedies for prevention of pests, claimed the interests of the keenest enthusiasts.

A display of early-flowering Chrysanthemums had been arranged, and Mr. Woolman, Mr. J. Coley, Duffield, and Mr. A. H. Harrison, Melbourne, put up collections, while the competition for the best vase of six disbudded blooms brought three exhibits in the professional gardeners' class, and six in the amateurs'. Mr. A. Turner, of Newton Solney, gained first prize in the former class, and Mr. A. Whitehurst was the winner in the latter, the flowers approaching the size of Japanese varieties; Certificates of Merit were also awarded.

Mr. Woolman, in responding to a hearty vote of thanks, spoke in high praise of the progress and activities of the Derbyshire Association, over two hundred new members having joined during the past twelve months, and he urged all lovers of the flower to do all they could to bring it into still greater prominence. After the meeting, the blooms were sold in aid of the Mayor's Hospital Fund.

GENERAL BULB GROWERS' OF HAARLEM.

The Gladiolus Committee of the above Society has made the following awards to Gladioli during the current year:—

First Class Certificates.

Abricot.—Golden-yellow, shaded apricot, with carmine stripe. Entered by Messrs. Bierde.

Mount Everest.—Flowers paper-white, in a broad, extremely well-formed spike. Also awarded a Trial Garden Award. Entered by Messrs. Alkemade.

Norma.—Flowers cherry-red, with a large, white blotch. Entered by Messrs. P. Byvoet and Co.

Rosette.—Soft pink, with small, carmine stripes. Also Trial Garden Award. Entered by Messrs. Alkemade.

Awards of Merit.

Adoration.—Scarlet. Entered by Messrs. Alkemade. Also received Trial Garden Award.

Anni.—Clear salmon-pink, with orange-scarlet yellow-striped blotch. Entered by Messrs. P. Byvoet and Co.

Asa.—Violet-purple with velvet sheen. Entered by Messrs. Pfitzer.

Azurea.—Soft bluish-violet, purple striped. Entered by Messrs. Pfitzer.

Chamberlain.—Salmon, with a scarlet blotch. Entered by Messrs. Alkemade.

Czardas.—Flaming scarlet with a dark purple stripe. Entered by Messrs. Alkemade.

Frans von Schubert.—Soft apricot-yellow, with a distinct, deep scarlet blotch. Entered by Messrs. Pfitzer.

Frau Dr. Adenauer.—Salmon, with vermilion stripes. Entered by Messrs. Graetz.

Garden Love.—Very soft, clear pink, with creamy blotches. Entered by Messrs. Alkemade.

Generalstab.—Cochineal-carmine. Entered by Messrs. Pfitzer.

Gloria Mundi.—Golden-yellow, without blotches. Entered by Messrs. Pfitzer.

Godetia.—Apricot rose, carmine striped, with geranium-red blotches. Entered by Messrs. N. and J. Roozen.

Good Hope.—A sport of Venus; rosy-white; semi-double flowers.

Graf Zeppelin.—Orange-scarlet, white-feathered, large flowers.—Entered by Messrs. Pfitzer.

King of the Reds.—Deep scarlet, with velvet sheen. Entered by Messrs. Pfitzer.

Libelle.—Violet. Entered by Messrs. Pfitzer.

Maagd van Orleans.—Milky-white, shaded cream. Entered by Messrs. Pfitzer.

Massenet.—Vermilion-red on pink. Entered by Messrs. N. and J. Roozen.

Mother Pfitzer.—Sulphur-white, shaded green. Entered by Messrs. Pfitzer.

Mr. Dix.—White, with creamy blotch. Entered by Messrs. Pfitzer.

Perle des Jardins.—Very soft strawberry-pink. Entered by Messrs. Alkemade.

Pink Pearl.—Soft pink-rose, creamy-white blotches. Also Trial Garden Award. Entered by Messrs. P. Byvoet and Co.

Poolija.—Pure white. Entered by Messrs. Pfitzer.

Queen Louise.—Clear white, shaded creamy-white on the falls. Entered by Messrs. Pfitzer.

Queen Mary.—Orange-pink, with purple-striped blotch. Entered by Messrs. Alkemade.

Red Beauty.—Geranium-red. Entered by Messrs. Alkemade.

Rheinperle.—Creamy-white, feathered pink. Entered by Messrs. Graetz.

Rokoko.—Soft china-blue, with purple marked, violet blotches. Entered by Messrs. Pfitzer.

Summer Beauty.—Distinct soft carmine-pink, somewhat deeper flamed at the ends of the petals. Entered by Messrs. Velthuys.

Verdi.—Pink, with large, creamy-white blotches. Entered by Messrs. Alkemade.

Wolga.—Scarlet, with carmine blotch. Entered by Messrs. Pfitzer.

Bianca (primulinus).—Sulphury-white. Entered by Messrs. P. Byvoet and Co.

Grandiflorus Rosemary.—Peach-rose and creamy-yellow. Entered by Messrs. P. Byvoet and Co.

Scarlet Bedder.—Deep orange-scarlet. Entered by Messrs. Salbach.

Grandiflorus Vestris.—Salmon, with small, blood-red spots on the falls. Entered by Messrs. P. Byvoet and Co.

Trial Garden Awards.

Ariadne.—Geranium-red, with scarlet, white-edged blotches. Entered by Messrs. P. Byvoet and Co.

Carolus Clusius.—Soft cattleya-pink. Entered by Messrs. K. Velthuys and Co.

Captain Boyton.—Violet, with purple-violet blotches on the falls.

Doris.—Apricot, with carmine stripe. Entered by Messrs. Alkemade.

Harmony.—Very soft pink, with a cream, carmine-feathered blotch. Entered by Messrs. Alkemade.

Ismene.—Violet-white, with a cream blotch; spike broad. Entered by Messrs. P. Byvoet and Co.

Mont Cenis.—Pure white. Entered by Messrs. Alkemade.

Mrs. Alice Amos.—White, with a creamy blotch. Entered by Messrs. Alkemade.

Ne Plus Ultra.—Flowers pure white, in a big spike. Entered by Messrs. Alkemade.

Rheinweiss.—Soft sulphur-yellow, with a butter-yellow blotch. Entered by Messrs. P. Byvoet and Co.

Salvation Rosa.—Soft strawberry-pink, with a carmine blotch on the falls; spike slender. Entered by Messrs. P. Byvoet and Co.

The Queen.—Satin-rose, with a small, scarlet blotch. Entered by Messrs. Alkemade.

Wagner.—Soft salmon-orange, with a cream-coloured blotch. Entered by Messrs. Alkemade.

Phantasy (primulinus).—Strawberry-pink. Entered by Messrs. P. Byvoet and Co., as also were the following primulinus varieties.

Hildegonde.—Salmon, with carmine stripes on the cream-coloured falls.

Leda.—Soft apricot, shaded yellow.

Lilac Favourite.—Soft cattleya-pink, with a soft yellow blotch.

Grandiflorus Rose d'Amour.—Clear salmon-pink, shaded.

Obituary.

John Cowan.—The passing of Mr. John Cowan, of Liverpool, on October 1, at the ripe age of eighty-seven, brought to an end the last of those great Orchid importers who flourished during a past generation, and who laid the foundations of the present day important industry. Few of to-day's Orchid enthusiasts will remember his great activities when the famed Vineyard Nurseries, at Garston, near Liverpool, was a huge emporium for receiving and distributing Orchids collected from all parts of the world. His dinamic energy and dauntless will carried him through many difficult and troublesome periods. Nothing was too big for him to tackle, from a ship-load of Orchids arriving in dock to the biggest private collection to be catalogued and disposed of in a couple of weeks! Such colossal courage as he often exhibited in these adventures deserved better returns, but, few men can have toiled so hard and "caught so little." Being a merchant rather than a cultivator, he found himself scarcely equipped for the change of taste when hybrid Orchids began to appear frequently and imported plants became less and less in demand. He retired gracefully from the new scene of action leaving two of his sons to carry on the name in another and more up-to-date sphere—now at Southgate. A great personality, but rather impatient, and sometimes a trifle irritable, not suffering fools gladly—John Cowan, nevertheless, was not an unreasonable chief. Always a furious worker himself, it was impossible for his staff to be idle, and none of the young men (the writer among them) who passed through his hands during his busy days, will have regretted their experience. His sympathetic nature was often imposed upon; probably his benevolent appearance and leonine head exposed him to that sort of thing! He will be remembered with affection by those who knew him personally, and with appreciation by those who remember to give him credit for all he did to popularise Orchids. It is good to know that the latter years of his life were spent peacefully at Gateacre, where, up to the last, he took a delight in keeping himself acquainted with what was going on in the Orchid world. *H. H. S.*

Geardus van Noordt.—Horticultural papers in Holland give news of the death, on October 5, at the age of sixty-nine years, of Herr Geardus van Noordt, one of the best-known nurserymen of Boskoop, Holland. For many years he was president of the Boskoop branch of the Dutch Horticultural Society, and took an active part in its work.

Emile Rosette.—We regret to learn of the recent death of a well-known French Chrysanthemum grower, M. Emile Rosette, of Caen. He was passionately devoted to Chrysanthemums, and had played, for the past thirty years, a large part in the development and improvement of the flower. He was considered one of the best cultivators in the country, and some of the exhibits he sent to the shows in Paris created quite a sensation. He was a Vice-President of the French Chrysanthemum Society, and had received the cross of the grade of Officer in the Order of "Mérite Agricole."

ANSWERS TO CORRESPONDENTS.

Iris Diseased.—*A. J. W.* The Iris rhizome has been attacked by the bacterial soft rot disease. Numerous larvae of one of the lesser Narcissus flies, Eumerus species, were present, but are probably secondary agents concerned in the decomposition of the tissues. Remove and burn all decaying portions and dress the beds with superphosphate of lime. The plants have received a check and this has opened the way to infection.

Lilium speciosum Bulbs after Flowering.—*W. H. D.* If the bulbs of Lilium speciosum are well established in pots, with plenty of healthy roots, the best plan is to leave them undisturbed until they commence to grow next year, when several inches of the top soil may be removed, and a topdressing of good loam, leaf-soil and sand given. If the bulbs are at present in small pots, it may be necessary, when they start to grow, to give them a shift into larger-sized pots. Remember that this is a stem-rooting Lily, and, therefore, fairly large, deep pots are necessary to allow plenty of room for the stem roots. They may be kept all the winter in a cold frame, or they may be stood out-of-doors, at the foot of a warm wall, plunged to the rim in ashes, or leaf-soil; in any case the pots should be covered over the top with several inches of clean leaf-soil, or fibre, or well weathered ashes will answer the purpose. If the plants are in poor condition, with very few good roots, they should be turned out and cleaned, afterwards repotting them in fresh compost and wintering them in the same way as advised for well established plants.

Rose Bush Unhealthy.—*H. K.* We were unable to find on the Rose bush any other diseases than mildew and rust, which you mention, nor any disease to which is attributable the collapse of the plant. The cause of the trouble appears to be traceable to the root system, which is quite inadequate for the task of supplying sufficient water requirements to such a large plant. A heavy mulching in spring should be adopted to induce the formation of fibrous roots, of which the plant submitted was almost devoid.

Single Dahlias.—*L. S.* The larger of the two seedling Dahlias is of good colour but appears to be rather floppy, although it may not be so when freshly cut; we liked No. 2 best because of its brilliant colour and good substance. You should have them tested in a large collection, as it is only by comparing habit, freedom of flowering, and length of stem that a proper estimate of their usefulness can be made.

Water Grass on Lawns.—*G. H. H.* If you are desirous of eradicating the water grass on your lawn, we recommend removing the affected parts and relaying with a turf consistent in texture with the lawn grass. If the desired quality of turf cannot be obtained in your district, we further recommend removing the patches, making up with a good loam, and incorporating a quantity of well-decayed farmyard manure, and sowing down immediately with a good mixture of grass seeds (excluding Rye grass). The sowing should give you every satisfaction and may prove to be the more economical method.

MARKETS.

COVENT GARDEN, Tuesday, October 15, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—The general conditions have shown some improvement during the past week. Carnations have realised better prices, also Chrysanthemums, especially good spray white. Among disbudded varieties, medium-size blooms of Bronze Alcalde and Almirante are most prominent; more blooms of Cranford Pink, Uxbridge Pink and Profusion are now arriving in good condition, and exhibition blooms have increased in quantity, the principal sorts being N. Davis, Edward Page, Yellow Edward Page and In Memoriam. More Lily-of-the-Valley has been on sale, including small consignments from Holland. Chrysanthemums and Gladioli are also arriving from this quarter in a sound condition, but Gladioli are now practically finished for this season. Roses are still on offer in very fine condition and prices remain steady. Arums (Richardias) show some improvement in quality, but arrivals are still very erratic. Larger consignments of flowers are now coming to hand from Cornwall, and include some very fine single Anemones, Violets, Forget-me-nots and spray Chrysanthemums. Small consignments of blue Cornflowers, Scabiosa caucasica and Marigolds are on sale from home-growers. All Asters are practically over for this season. There is a good supply of such foliage as Asparagus plumosus, A. Sprengeri and Maidenhair Fern, but it is somewhat varied in quality. Smilax is arriving from Guernsey in a sound condition, and there is also a good selection among hardy foliage, good-coloured Oak being most in demand at present. In the pot plant department some very fine Cyclamens are now on offer in 32's, 48's and 60's. Ericas and Chrysanthemums in pots are also more plentiful, and the usual Palms and Ferns are now receiving more attention.

Remarks.—There has been some slackening in the general inquiry in most departments and trade, on the whole, is not good. In the hothouse fruit section there is some congestion of produce, and prices are on the low side, particularly for Grapes. There are not so many English Apples available at the moment, and Worcester Pearmain is getting to the end of its season. Cox's Orange Pippin shows a gradual increase in supply, and prices are fairly good. Large cooking Apples are not plentiful, but even so, there are few high prices being realised. Some good Pears are being marketed just now, but with such excellent Doyenné du Comice and Beurré Hardy Pears from California, buyers are not much interested in the English fruits. Mushrooms are plentiful and cheap, the recent rains having encouraged the production of field Mushrooms, which are coming along in heavy supplies. The past week has seen a slump in the values of forced Beans, owing to increased supplies of Peas and Runner Beans. Green vegetables, generally, are selling but slowly and prices cannot be termed good. English Tomatos have shown a shade of improvement in prices, owing to a slight reduction in supplies, and even outdoor Jersey Tomatos, if of good quality, are realising rather more money. The Cucumber trade is firm, with little variation in prices. There is some slight improvement in the Potato market, and quotations are inclined to harden.

GLASGOW.

Characterised by a dull time early in the week, the cut flower market experienced a sharp advance in prices of Chrysanthemums later, and at the close advances ranging from thirty-three to fifty per cent. were recorded on the previous week's quotations. Disbudded blooms of Cranford Yellow were worth from 1s. 6d. to 2s. 9d. for 6's.; Pink Consul, 2s. to 2s. 6d.; Bronze Consul, 1s. 6d. to 1s. 9d.; Almirante, 1s. 4d. to 1s. 9d.; Le Pactole, 1s. 3d. to 1s. 8d.; Debutante and Holicot Yellow, 1s. 3d. to 1s. 6d.; Sanctity and Holicot Bronze, 1s. to 1s. 6d.; Dolores, 10d. to 1s. 3d.; sprays, 3d. to 6d.; and large bunches, 6d. to 10d. each. Carnations sold at from 2s. 6d. to 4s. per dozen; pink Roses, 2s. to 3s. 6d.; red, 1s. to 2s. 6d.; Richardias, 3s. to 4s. per bunch; Michaelmas Daisies, 4d. to 1s. 6d.; Calendula, 2d.; Ruscus, 12s. 6d. per pad; Solanums, 14s.; Chilis, 7s.; Smilax, 1s. and 2s.; and Asparagus, 3d. to 1s. 3d.; trails, 1s. 6d. to 2s. 6d.

Imports of American Apples which are arriving in the Clyde in good condition made the following prices:—McIntosh Red, 16s. to 20s. per case; Jonathan, 14s. to 17s. 6d.; David and Grimes Golden, 14s. to 15s.; Nova Scotia Wealthy, 25s. to 30s. per barrel; Gravenstein, 25s. to 26s.; and King of the Pippins 30s. to 33s. Doyenné du Comice Pears made 27s. per case; Winter Nelis, 26s., and Beurré Hardy, 25s. to 30s.; Scotch Burnett Plums sold at 2d. to 3d. per lb.; Damsons, 4d. to 5d.; Blackberries, 5d. to 6d.; Cranberries, 6d.; Peaches (Italian), 8s. per package; Pineapples, 5s. 3d. each; home-grown Grapes, Alicante, 2s. 6d. per lb.; Black Hamburgh, 2s.; Gros Colmar, 3s. 6d.; and Muscats, 4s. 6d.

Tomatos fluctuated between 6d. and 9d. per lb.; Cucumbers, 3s. to 6s. per doz.; Cauliflowers, 3s. to 7s.; Lettuces, 2s. to 2s. 3d. per box (15's and 18's), and Mushrooms, 3s. to 3s. 6d. per lb.

WEATHER IN SEPTEMBER.

Before the end of August the drought had returned, and September, to within three days of its close, was mainly a fine, dry and warm month, with an unusual prevalence of light sea breezes. But for a valuable heavy fall of rain—over an inch—during the night of 28th to 29th, it would have been much the driest month so far, in 1929. Even so, measurable rain fell on only six days, or nine fewer than the average number; and the total quantity did not quite equal two inches, which implies a deficiency of 1½ inch. The ground water level became exceedingly low. The mean temperature was 57·8°, or 2·5° above the average. The duration of sunshine amounted to 157 hours, or to 17½ hours more than the normal. The afternoons yielded 22 more sunny hours than the forenoons. The great bulk of the month's small rainfall fell during the early mornings—before 9 a.m. Gales were restricted to the 20th and 21st, and moderately high winds to the 19th and 22nd; all other parts of the month were remarkably calm. Several early morning fogs were reported, but none between 9 a.m. and sunset. Only one, very slight, thunderstorm occurred (on the 12th). No trace of frost was recorded. *Joseph Baxendell, The Fernley Observatory*, Southport.

THE ENGLISH ROCK GARDEN
by
The late REGINALD FARRER
PRICE (two volumes) £3 3s.
Postage extra 1/3
This wonderful book remains, and is likely to remain indefinitely, the classic of the rock garden, for since Farrer no new prophet has arisen in this realm of horticulture. He wrote the book not long before his tragic early death, and there is in it all the flame and ardour of his wonderful genius. To read its pages is to walk with Farrer through the rock garden, and hear his vivid, forceful comments on each of its denizens.

Nature Reserves.

The Conference recently held at Manchester on the preservation of the countryside is doing admirable work in keeping before the public the need for active measures if the beauty of rural England is to be maintained. No country in the world is more beautiful, no people in the world is more possessed with a feeling for natural beauty, and therefore it should prove by no means impossible to create and foster a public attitude toward the countryside which would make its desecration impossible. We are glad to learn, from the stimulating address which he gave at the Conference, that Lord Grey of Falloden holds this view fervently. He points out that public opinion already upholds the sanctity of flowers in our public parks. The high standard which parks-gardening has reached is appreciated by all classes of the community and by none more than by that which is commonly called the working class. In like manner, Lord Grey hopes, and we agree fully with him, that a deep and strong respect for the beauty of rural England may be quickened in the general mind. That it exists already —overlaid it may be by indifference due to unfamiliarity—is certain. The cottage gardens of England attest it; all that is needed is a little education—in the literal sence of the word—for the latent to be converted into a patent appreciation. Municipalities have in the past been much to blame in sanctioning and consecrating ugliness in buildings, in alignment of streets and so forth. But this remissness is now of the past, and towns are beginning to vie with one another in beautifying themselves. Our seaside resorts—of the east coast, Scarborough for instance, of the west coast, as Southport may testify, and of the south coast, as exemplified by Eastbourne—begin to be more plentifully and beautifully supplied with gardens than are any other seaside resorts anywhere. A visit to any of these places or, for that matter, to Kew, on Saturday afternoon, will suffice to show how widespread and intense is the feeling for the beauty of gardens. Something more—indeed much more—might, of course, be done to foster this feeling, and that without any sentimental mawkishness. Our public schools might do much more to spread a discriminating love of natural beauty among the boys. It should be regarded at least as disgraceful to be ignorant of the names and peculiarities of our common trees as to be ignorant of the tenses of *amo*. Yet, although a good deal of science is taught in our public schools, and although in some Nature study is encouraged, that study is not, as, of course, it should be in a really civilised state, universally followed. To an even more marked degree neglect of the study of living things and the countryside which supports them is common in our secondary schools, where sciences—made arid by the classroom and laboratory—are badly, or, at all events, stuffily pursued. Of the people so deprived of one of the chief pleasures of life—the enjoyment of rural beauty—some come up to Universities and in fulness of time go down from them without having their attention directed to this serious omission in their education. Naturally they were busy with other things, such as careers, and games and books, and human intercourse; all the more reason then that at some time or other the rising generation should be reminded of their increasing urbanisation and of the disabilities which attend thereon. Lord Grey, in pleading for the education of public taste in rural things, makes a number of useful suggestions; the planting of suitable flowering and other trees in the country—the careless tyranny of the Elm is too strong in England—and the clipping of hedgerows so as to leave at intervals the Thorn or other plant to grow as it will. The ruthless rooting up of wild flowers is, of course, to be deplored; but, except where hawking is concerned, it comes from an ill-balanced appreciation of objects sought after and would soon correct itself when knowledge exercised its restraining power. Given wise leadership, ugliness, which until recently was accepted as insuperable by high industrialists, will be exorcised, and the natural beauty of the countryside of these islands, which has given solace and joy to countless generations in the past, will be preserved and enhanced to the benefit of the health and happiness of the generations yet to come.

Retirement of Mr. Charles H. Wright, A.L.S.—After forty-five years' service in the Herbarium of the Royal Botanic Gardens, Kew—commencing on September 1, 1884, when he came from the Herbarium and Library of the Oxford Botanic Garden—Mr. C. H. Wright has retired under the age limit. The *Kew Bulletin* records that among his many activities during his long period of service at Kew, one of the most important was in connection with the building of the new wing of the Herbarium. Mr. Wright was assigned the task of rearranging the collection and organising the whole of the moving over of the spceimens and arranging them in the new wing—a task for which, by reason of his well-known accuracy and mastery of method, he was peculiarly fitted. For many years, all the detail work in connection with the receipt and despatch of specimens had been in his hands, and his knowledge of the history of the Herbarium collections has enabled him to render very valuable services to Kew. Another important piece of work which he has carried out has been the reading of the proofs of the African Floras—a task needing meticulous accuracy and attention to detail. In addition to these many duties he has been able to carry out a considerable amount of systematic research-work. His loss to Kew will be felt very greatly, since for many years past he has been in charge of the Palms and Petaloid Monocotyledons, and the Ferns and Mosses. As specialists on the Cryptogams are now few in number, it will not be easy to find anyone to take Mr. Wright's place in this particular and very important field. In the year 1896 he was awarded the distinction of the Associateship of the Linnean Society. He leaves Kew with the best wishes of all his colleagues that he may fully enjoy the leisure of his retirement. A portrait and appreciation of Mr. C. H. Wright appeared in *The Gardeners' Chronicle* of July 16, 1927.

The King's Gift to the Royal Gardeners' Orphan Fund.—So that this deserving gardening charity should not suffer through the abandonment of the Sandringham Horticultural Society's Show on account of the King's illness, His Majesty commanded that a donation of £15 be sent to the R.G.O.F. Needless to state, the King's thought for the orphans has been immensely appreciated by the Fund.

Imperial Fruit Show.—We learn, at the time of going to press, that preparations for the ninth Imperial Fruit Show, which opens at the end of the current week, are complete. The show, which has been staged in Bingley Hall, Birmingham, covers a floor area exceeding 60,000 square feet, and will remain open to the public until Saturday, November 2. In the Empire Marketing Board's section are representative exhibits of fruits of the Home Country, Canada, Australia, New Zealand, South Africa, Malaya and the West Indian Colonies. The Ministry of Agriculture is responsible for demonstrations of packing and grading fruits for market by means of the latest machines, and featuring the new National Mark for home-grown produce, while it is estimated that at least three thousand packages of fruits are displayed in the various competitive classes, for which £1,500 in cash, cups, trophies, etc., is offered. The research stations of Long Ashton and East Malling are represented; there is a window-dressing competition; an ideal fruit shop, and a "Palace of Beauty." On Wednesday, October 30, there will be a conference organised on a national basis for retail fruiterers, who will be widely represented, while on the following day an invitation luncheon and conference for fruit-growers has been arranged. During this conference a number of films dealing with the fruit industry will be shown. Each visitor to the fruit show will be presented with a free sample of Empire fruit, either Apples, Oranges, Grape Fruit, Limes, or canned fruits, and this year a proportion of all growers' exhibits staged will be sold to the visiting public in small quantities at normal prices. The railway companies and the Midland Red Motor services are co-operating in the matter of special excursions and cheap return tickets to the Imperial Fruit Show.

September Rainfall.—The British Rainfall Organisation (Air Ministry) informs us that it is now possible to state that the rainfall over the British Isles as a whole during September, 1929, was just less than half the usual amount. During the past sixty years there have been four drier Septembers, of which only those of 1907 and 1910 were appreciably drier, and those of 1894 and 1895 were slightly drier. The drought was most intense in the south of England, in the south-east of Scotland, and in the neighbourhood of Dublin, where the total fall amounted to less than a quarter of the average. In parts of Surrey, Hertfordshire and Buckinghamshire rain fell only on the last two days of the month. The total rainfall recorded over the

British Isles up to the end of September this year was less than that of any similar period in the last sixty years, although there was very little more in 1870, 1887 and 1921. Over England and Wales alone, January to September, 1929, was drier than any similar period in the past sixty years, the general fall being 15·0 inches compared with 16·7 inches in 1870, 17·0 inches in 1921, and 17·4 inches in 1887. In both 1887 and 1921 the last three months of the year were dry, so that it is by no means certain yet that 1929 will rank as the driest year on record. The relatively wettest parts of England and Wales were the Devon-Cornwall peninsula, western Wales and the English Lake District, where the rainfall of the nine months, January to September, 1929, was about three-quarters of the average amount. Rather less than half the average was recorded in the neighbourhood of Margate and Skegness, and over a large area stretching from Woburn in Bedfordshire to Southampton. At Oxford, the total rainfall (44 per cent. of the average) was only about 7·5 inches, or 1·5 inch less than that recorded in the previous driest group of nine months during the past sixty years, viz., February to October, 1921.

Successful Peach Culture at Teston.—Our veteran friend and correspondent, Mr. George Woodward, of Barham Court, Teston, Maidstone, is well-known as a successful cultivator of fruit, and as a particularly successful grower of Peaches. These last he grows for market, and during the present season has sent to Covent Garden no fewer than 16,161 fruits, and of this number only 3,000 were grown under glass. This has, of course, been a good Peach year, but Mr. John Poupart, the salesman, assures us that in his long experience he has never handled such splendid fruits—they were triumphs of skilful cultivation.

Progress of the Balfour Forest in Palestine.—At a meeting of the Jewish National Fund, held at the Mansion House recently, Lord Melchett referred to the progress that has been made in the planting of the Balfour Forest on the hills of Judea. He stated that two years ago 57,000 trees were planted, and last year 151,000 were planted, and it is hoped that within the next few years the work would be completed, greatly to the advantage of the country and the climate.

Manchester Exhibitions.—The Royal Botanical and Horticultural Society of Manchester and the Northern Counties will hold a Chrysanthemum show in the Town Hall, Manchester, on November 12 and 13, when thirty-four classes will be arranged and handsome prizes, including Cups and Gold, Silver-gilt and Silver Medals, offered. The Schedule of the Spring Show, to be held in the Town Hall, on May 6 and 7, 1930, has been issued, and this contains forty-two classes, in which the sum of £250 is offered as cash prizes, in addition to Gold, Silver-gilt and Silver Medals. The Secretary is Mr. Arthur Eastwood, 59, Ennismore Street, Burnley.

Apple from an Australian "Pip."—Writing from Orton Hall, Peterborough, the Marquis of Huntly states:—"In 1887, my brother, Granville Gordon, took a fancy to some Australian Apples that had been imported. Seedlings were raised from the pips, and one was planted in the garden here. The tree, now forty-one years old, has been a luxuriant grower and good bearer, and its height is about twenty-five feet. This week (October 17) we have gathered 4,015 Apples from it, all of good and average size, entirely free from maggots and disease. This appears to be an exceptional record!"

Historic Headquarters of the French Ministry of Agriculture.—The French Ministry of Agriculture is housed in a building of considerable historic interest and architectural beauty, namely, the mansion in the Faubourg St. Germain, formerly known as the Hôtel de Villeroy. Our French contemporary, *La Vie a La Campagne*, in its October issue, gives some interesting photographs and details of the house, which was originally erected at considerable cost, in 1720, by the Baron de Presles, for his mistress, Charlotte Desmares. It was sold in 1746 to the Marquis de Villeroy, and, later, changed hands several times, becoming the headquarters of the Ministry of Agriculture in 1881. Many of the interior decorations of the eighteenth century have been retained, and the lofty salons with their handsome tapestries and hangings are eminently suited for the receptions which the Minister and Madame Hennessy hold from time to time. The garden is very much smaller now than when the house was first built, and its style is completely changed. It was originally laid out in the formal style prevailing at the beginning of the eighteenth century, but at various later periods alterations were made, Cedars and other large trees planted, and in the reign of the Emperor Napoleon III it was completely re-arranged and laid out afresh by Barillet-Deschamps, a former gardener of the Bordeaux gardens, who was promoted to be the favourite garden-designer of the Emperor.

Herr F. Kunert.—Gartendirektor F. Kunert, of Sanssouci, the famous castle near Potsdam (built by Frederick the Great), retired with a pension on October 1. He was born in 1863, in Silesia, and spent the early years of his gardening career in various private estates in that province, where many famous gardens used to be and some of which are still existing. In 1895, Herr Kunert entered the service of the former Emperor William II, and took charge of the famous Terrassen-Revier in Sanssouci, where fruits of all kinds are grown under glass. Later on he built a very fine modern range of greenhouses for Grape and Peach cultivation, as well as for stove and greenhouse plants for the decoration of the castle, etc. He became so famous as a skilful cultivator all over the country, that the Emperor appointed him as his Oberhofgärtner, and he was the recipient of many decorations from the former German Emperor and royal visitors. After the great change in 1918, Herr Kunert remained in charge of his department, and was appointed Garten Ober-Inspektor, and a few years later received the title of Garten Direktor. He has now left this position owing to the age limit, but as he enjoys good health, it seems a pity that his knowledge and great experience should remain unused. Herr Kunert is certainly one of the best plant cultivators in Germany, and his successes at Sanssouci included fruits, Orchids, Chrysanthemums, Amaryllis, Carnations, Lilies and general greenhouse and stove plants, and all were of the highest standard of quality and admired by everybody who had an opportunity of visiting his department at Sanssouci Park.

HERR F. KUNERT.

Pomological Conference in France.—The sixty-fifth Congress of the French Pomological Society took place on September 20 and 21, at Clermont-Ferrand, in the large amphitheatre of the Faculty of Letters. The first session opened at 9 a.m., with about a hundred members present, M. Castaigne, the Director of the Medical College, taking the chair in the absence of the Rector, M. Lirondelle. A number of interesting papers were read, and it was decided to hold the next Conference at Chambéry, in 1930. The close of the Conference was marked by a banquet, at which 120 guests were present, and a number of excursions were made on subsequent days to places of interest in the vicinity. The Conference had been fixed to coincide with the local horticultural exhibition, held from September 19 to 23, in the Jardin Lecocq. The Grand Prix d'Honneur was awarded to MM. Cayeux et Le Clerc, of Paris, for a splendid collection of Dahlias and Gladioli, and a second Grand Prix was won by M. Perdoux, of Bergerac (Dordogne) for a display of Grape vines in excellent condition. Groups not for competition were sent by the Luxembourg Gardens, Paris, with a fine collection of Rex Begonias and Adiantum cuneatum; and by the Syndicat des Horticulteurs et Pépiniéristes du Centre, which displayed mixed flowers, Dahlias, Roses, Carnations, etc., with a wonderful lot of Reinette du Canada Apples, of a quality never seen except in Auvergne and in certain regions of the Pyrénées Orientales, where they are produced in huge quantities.

Successful National Cactus Show in America.—Interest in Cacti and other succulent plants continues to increase in the United States, and is being fostered by the recently instituted Cactus and Succulent Society of America. This Society held its first show at the Rust Nurseries, Pasadena, California, at the end of August, and we learn that it was a great success, the exhibits being of high quality and interest and the attendance good.

R.H.S. Award of Garden Merit.—Seven plants are recorded as having received the Royal Horticultural Society's Award of Garden Merit, in Part 2. Vol. LIV, of the *Journal* of the Royal Horticultural Society (September, 1929), making a total of one-hundred-and-fourteen plants which have been so honoured. Kerria japonica was given the Award on June 7, 1928. The single form is stated to be better worth growing than the double form, which was introduced first from Japan so long ago as 1700. The single form is hardier than the double, and is quite safe out-of-doors in any ordinary soil and situation. Aster Thompsonii was given the Award on October 3, 1927; a native of the Himalayas, few herbaceous perennials have a longer season of flowering than this Aster, which produces its first blooms in July and maintains a succession of them into October. The flowers are about two inches across, and the ray florets pale blue. The type attains two feet in height, but there is a dwarfer form, equally desirable and called variety nanus, about eighteen inches high; crossed with A. Amellus by M. Frikart, A. Thompsonii produced a race of plants of good form, rather more floriferous, and with larger flowers, called A. × Frikartii, the best form being the variety Stäfa. The Award of Garden Merit was bestowed upon Astilbe simplicifolia on August 8, 1927, a plant which has received considerable notice in this journal; A. s. var. rosea was the subject of the Supplement Plate in our issue of August 24. Spiraea venusta, which received the Award also on August 8, 1927, is an herbaceous species of garden merit; it is very accommodating, for Mr. F. J. Chittenden states it will flourish in the open, sunny border (provided the soil is not too dry), in partial shade, and on the edge of the pond or bog. Its growths will attain a height of three to five feet, and are terminated in July and August with large, branching clusters of pink flowers. S. venusta is described in some works of reference under S. lobata, and is also synonymous with S. palmata, L. There is a variety of it called magnifica, with larger flowers of deeper colouring, while the flowers of variety albicans are light pink. The praises of Hypericum reptans, which was given the Award on July 4, 1927, have often been sung, for it is a highly ornamental subject for the rock garden. It forms a close mat of bright green which is studded, from August until frosts set in, with large, rich yellow flowers and almost crimson buds; it requires a moderately sheltered position to ensure it withstanding the winter, as it hails from Sikkim. The superior colouring and larger size of its flowers led to the variety of Ribes sanguineum (the Flowering Currant, so well known in English gardens) known as splendens, being selected for the Award of Garden Merit on April 4, 1928. R. s. var. splendens is as free-flowering as the type, and forms a shapely bush up to six feet in height, although it does not resent restrictive pruning. The last plant described as having received the award, on January 14, is the invaluable Viola Jersey Gem which was raised by Mr. T. A. Weston, of New Jersey, U.S.A., a not infrequent contributor to the columns of *The Gardeners' Chronicle*. Viola Jersey Gem is very popular in America, and soon gained favour upon its introduction to this country, for it is of compact, tufted habit, and very floriferous, while it produces its violet-blue flowers, of medium size, over a very long period.

Register of Growers of Certified Black Currant Bushes, 1929.—This Register, which has been issued recently by the Ministry of Agriculture and Fisheries, contains the names and addresses of growers of Black Currant bushes whose stocks have been examined during the past season by the Ministry's Inspectors, and certified as true to type and apparently free from reversion. Certification of bushes has followed the group classification adopted by the East Malling Research Station, with the exception that "Goliath" has been replaced by "Edina" as the type name of Group III. The four main groups, therefore, are I, French Black; II, Boskoop Giant; III, Edina and IV, Baldwin. Particulars of certified stocks of varieties not included in any of these groups will be found under the heading "Unclassified Varieties," at the end of the register. Except in the case of unclassified varieties, certificates do not guarantee that bushes are true to any particular variety, but where bushes have been stated by the growers to be of particular varieties included in the group types, those varietal names have been added in brackets. The certificates relate solely to the purity of the stocks and their apparent freedom from reversion at the time of inspection. They must not be regarded as guarantees of freedom from disease, although no stocks were certified which were obviously unhealthy or lacking in vigour at the time of inspection. Certificates are valid only up to April 30, 1930, and growers to whom they have been issued have given undertakings that they will be used only in connection with the bushes actually inspected and certified by the Ministry's Inspectors. Copies of the Register may be obtained upon application to the Ministry, 10, Whitehall Place, London, S.W.1.

Sterilisation by Heat of Small Quantities of Soil.—In view of the various opinions expressed in these columns recently on the question of soil sterilisation, and especially with regard to steaming versus baking, over which considerable controversy has arisen, the contribution by Dr. W. F. Bewley, Director of the Cheshunt Experimental and Research Station, to the October issue of the *Journal* of the Ministry of Agriculture, entitled "The Practical Sterilisation by Heat of Small Quantities of Soil," is of special interest. Soil sterilisation eliminates pests and diseases, and greatly increases the fertility of the soil, with the result that plants of increased vigour and health are assured. The soil is heated to a temperature of 210° to 212°F., and is maintained at that temperature for from fifteen to forty minutes, according to the type of soil and its contaminations. Dr. Bewley compromises on the question of steaming versus baking, stating: "Actually both methods are beneficial if properly conducted with due regard to the type of soil and the nature of its contaminations." Both methods increase soil fertility, and destroy obnoxious fungi and bacteria. Baking is more severe upon the soil colloids than steaming, and baked soil is more difficult to handle in potting than that which has been steamed, as it dries out more quickly and requires more attention—"many Tomato growers refuse to use it for this reason." Another risk engendered in baking the soil is that it is easy to overheat it, especially if the soil is on the dry side, with the result that it is rendered "dead" and incapable of supporting plant life; seedlings planted in such soil turn blue and hard and make poor, if any, growth. If steamed soil turns out of the steriliser like "so much thick mud," a not uncommon complaint, the method employed is wrong. Later, Dr. Bewley states his preference for steaming. Numerous devices for both baking and steaming soil, in quantities varying from half-a-ton to three tons, have been invented by nurserymen and others, and the most important of these are discussed very thoroughly by Dr. Bewley. Diagrams are given demonstrating the box method of steaming, and the Washburton Baking Apparatus, as used on Mr. G. Tabner's nursery at Timperley; the illustration of the Cheadle Royal steaming apparatus, which appeared in *The Gardeners' Chronicle* of December 22, 1928 (Vol. LXXXIV, p. 495, Fig. 221), is reproduced, and there is also an illustration of a very efficient soil-baking apparatus in use on Mr. W. Priestner's nursery at Northenden, Cheshire. The value of a particular sterilising device depends upon whether the method will provide a uniform temperature of at least 210°F. throughout the mass of soil in a reasonable time; whether it will turn the soil out in a condition suitable for plant growth; the cost of constructing and working the apparatus. In conclusion, Dr. Bewley states that steaming is, undoubtedly, the best method of sterilisation, and should be employed whenever possible; the box and grid method, fully explained in the text, and the Cheadle Royal method, are recommended, the latter being especially commendable for its ease of working. If steaming is impracticable, then baking should be considered, the apparatus recommended for this purpose being that devised by Holmes and incorporated in the Holmes' baking oven, the metal parts of which are sold by Messrs. C. P. Kinnell and Co., Ltd. Bakers of the Cheshire type have not been found to maintain a uniform heat.

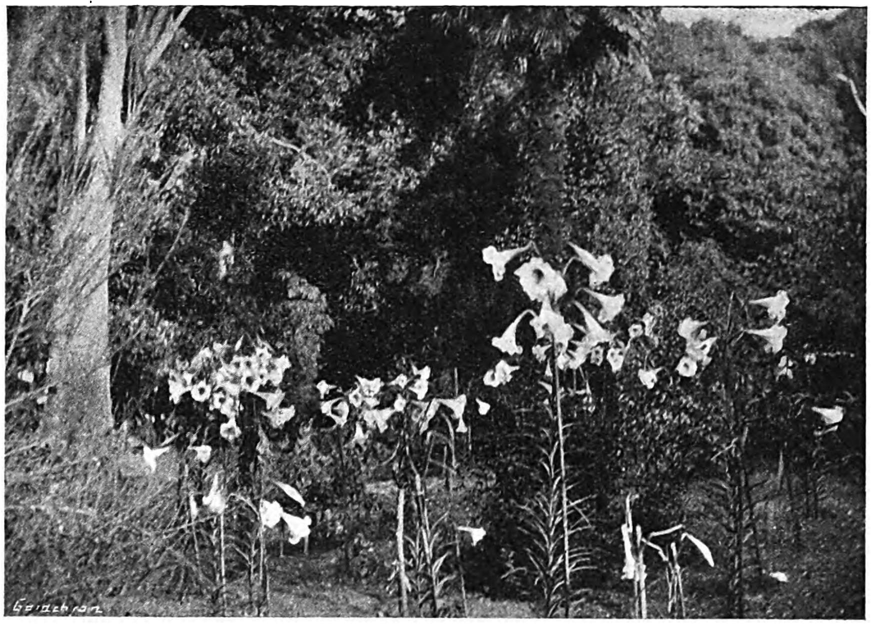

FIG. 148.—LILIUM PHILIPPINENSE VAR. FORMOSANUM AT ABBOTSBURY, WEYMOUTH.

(see p. 325.)

Appointments for the Ensuing Week.—Monday, October 28: Birmingham and Midland Counties Gardeners' Association's lecture. Tuesday, October 29: Croydon Chrysanthemum Society's Exhibition; Royal West Renfrewshire Horticultural Society's meeting. Wednesday, October 30: Eastbourne Horticultural Society's Autumn Show (two days); Guildford and District Chrysanthemum Society's Show (two days). Friday, November 1: Dundee Horticultural Society' lecture. Saturday, November 2: Leeds Paxton Society's open exhibition night.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Effects of the Past Winter.*—It is not a little remarkable that Garrya elliptica, an Oregon plant, naturally associated with Berberis aquifolium, Ribes sanguineum, Spiraea ariaefolia, and similar hardy plants should have suffered so generally; for although not killed altogether in any place from which reports were received, yet we know that it scarcely escaped with life in the immediate vicinity of London. No Spiraeas seem to have sustained material injury. The new evergreen shrub Swammerdamia antennaria, notwithstanding its Australian origin, proves as hardy as a common Laurel; nor is the Pittosporum bicolor, from the same country, much more tender. In speaking of Eucalyptus, we have already pointed out how much there is to hope from experiments with Van Diemen's Land shrubs, and these cases materially strengthen the probability. We may take this opportunity of adding that the Eucalyptis called montana, which has proved so hardy in the south of England, is not coccifera, as we suspected, but is the Van Diemen's Land radiata, as we have learned from specimens communicated by Mr. Luscombe of Combe Royal. Lastly, we have to record the unexpected fact that the Assam Tea plant is hardy. Several small plants in the garden of the Horticultural Society survived without the smallest protection; and, what is still more curious, a young plant in incipient leaf was very little damaged by the frost of April 24, which killed all the young wood of the Walnut trees. This may be taken as a further illustration of what we have said while speaking of Garrya elliptica, showing how impossible it sometimes is to judge *a priori* whether a new plant is hardy or not. It shows that the question is one that can only be answered by direct experiment.—*Gard. Chron.*, *October* 28, 1854.

Publications Received.—*The World's Grasses, their Differentiation, Distribution, Economics and Ecology*, by J. W. Bews, M.A., D.Sc., F.L.S.; pp. xii, 408, illustrated. Messrs. Longmans, Green and Co., Ltd., 39, Paternoster Row, E.C.4. Price 21s. net.—*Patio Gardens*, by Helen Morgenthau Fox; pp. xx, 228, with many illustrations. Messrs. Macmillan and Co., Ltd., London. Price 25s. net. *Journal of Forestry* (No. 4, Vol. XXIII), of the Royal English Arboricultural Society. Laughton and Co., Ltd., London. Price to non-members, 2s. 6d.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Duckyls Park, East Grinstead, Sussex.

Cypripedium Seedlings.—Where seeds of Cypripediums were sown early in the year, on the surface of the compost of older plants, and germination was successful, the seedlings should now require attention. The larger seedlings that have completed the formation of their first leaf, should be transplanted singly into very small pots, or several may be pricked out into store pots two-and-a-half inches in size, which have been prepared a few days previously and thoroughly watered, so that the moisture can be absorbed and the compost warmed through before the small plants are transplanted into it. The compost may consist of A.1. fibre and Sphagnum-moss cut moderately fine, in equal parts, for the very small plants, adding a little fibrous loam for the more advanced seedlings and incorporating a few finely crushed crocks to keep it porous. The whole should be mixed well together and pressed firmly into the pots, trimming the surface off neatly and level with the pot rim. Place the pots near the roof-glass at the warmer end of the house, and spray the plants and surroundings frequently with a fine sprayer to avoid disturbing the seedlings. Under genial and moist conditions, the plants quickly become established and should be kept growing steadily during the winter in favourable districts. Near large towns and manufacturing centres, where the light is usually very poor during the next two months, it is advisable to leave the pricking out of seedlings until early in the new year, when the increasing light should be more conducive to growth. Stronger plants that were pricked off earlier in the year, may require separating and potting singly, the size of the pots depending on the vigour of the plants. In all cases good drainage is essential to allow a free passage of water and air through the compost, which, for the tessellated section, need not contain any loam. The small plants are subject to attack by thrips, which should be kept in check by occasional fumigating, while the troublesome small black fly may be trapped by insectivorous plants, such as Pinguicula caudata, Drosera binata and D. capensis. The larvae of this fly churns up the compost and disturbs the small seedlings, often necessitating their removal to fresh compost. A few of these insectivorous plants grown among the seedling pots serve a useful purpose and many of them are attractive and interesting subjects.

Oncidiums.—Cool house Oncidiums, of the macranthum type, which have just flowered, should be given ample supplies of water at the roots each time the compost appears dry until growth is complete, when a smaller quantity will suffice, although plants of this section of Oncidium should not be kept dry at the roots over a long period at any time. Scale insects often infest these Orchids, and should be removed so soon as detected.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Preparation for Planting.—Two of the essential conditions in the successful cultivation of hardy fruits are efficient drainage, and deep and thorough cultivation of the soil. The lack of efficient drainage is the predisposing cause of most of the fungus diseases which attack fruit trees. Chlorosis, gumming and canker in all its forms, are brought about by the enfeebled condition of the trees, caused by impaired sap supply owing to bad drainage. When the soil is water-logged the air is driven out, and the roots of trees cannot be healthy unless oxygen from the air can penetrate the soil freely. But when the soil is properly drained, the water, during heavy rains, passing to the drainage, draws the air into the soil. Land that is drained is certain to be a more healthy medium for fruit-growing than that which is undrained. Good drainage raises the temperature of the soil, by admitting warm atmospheric air, and so makes it more productive, and the fruits mature earlier and are more highly coloured. A well ventilated soil aids the useful bacteria in the preparation of plant foods; besides, drainage improves the physical condition of most soils. Where drainage, for some reason or other, is found to be impracticable, plant the trees on mounds raised slightly above the general level of the soil, and keep the surface of the mound well mulched with manure, especially in summer, so as to attract and retain the roots near the surface, for if this becomes dry in hot weather, the roots may go downwards in search of moisture, to the detriment of the trees.

The Soil.—The preparation of the soil should be taken in hand at once, so that it may have time to settle down before the actual planting takes place. It should be worked to the depth of at least two feet, the subsoil being broken up, but not brought to the surface. Where it is intended to plant a whole plot, or a complete row, the preparation may be carried out by bastard trenching the whole area. If the subsoil is of a retentive or clayey nature, bonfire-ash, road scrapings, chalk, or mortar rubble, should be incorporated freely during the process of trenching. This will help to keep it open for many years and prevent the clay ever becoming so compact again. Neither leaf-soil nor animal manure should be introduced into the soil, either now or when planting Apples, Pears, Plums or Cherries, as they cause rank growth which seldom ripens properly, and the trees would, most likely, require lifting and root-pruning after a few years. Healthy roots working actively in sufficiently fertile, yet quite firm, but porous soil, should be the aim of all growers of hardy fruits. If the soil is too rich and too loose, the natural result is displayed in the form of gross, sappy growths and few blossoms. In the case of small fruits, however, such as Gooseberries, Currants, Raspberries and Strawberries, manure should be incorporated freely in the soil to obtain the best results. If the land is under turf, the turf should be chopped up as the work proceeds and placed over the broken bottom spit, the soil from immediately beneath being moved over on top of this. Leave the surface so rough as possible to "weather" down naturally by frost, rain, and drying winds. Left in this way, it will drain better, dry quicker during a spell of fine weather in early winter or in February, and there should be plenty of friable soil on the surface to place about the roots of the trees as they are being planted.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Campanula pyramidalis.—Plants of the Chimney Campanula raised from seeds sown last spring, and intended for growing in pots to furnish the conservatory and dwelling-house next season, should be placed in their flowering pots. Receptacles seven inches in diameter are most suitable for this purpose, and the plants should do well in quite ordinary soil, provided a little bone-meal is added. After potting, they should be placed in a cold frame, plunging them in a bed of ashes well up to the rims to prevent the pots being broken by severe frost; remove the lights on all favourable occasions. Stocks of this popular Campanula may also be raised from root-cuttings.

Irises.—There are several sorts of Iris that have become popular for pot culture and among them the most favoured are I. tingitana, I. Imperator and I. praecox, the two last coming into flower about a fortnight before the Spanish Iris. I. tingitana may be had in flower early in December if required, provided the bulbs are procured at an early date. Although this Iris cannot be forced under a high temperature, bulbs potted now should flower during January. If grown in a temperature not exceeding 55°, Iris Imperator and I. praecox respond well to pot cultivation; if their flowers are required in quantity for cutting they may be grown in boxes. They should always be watered very carefully, and any attempt to force them under a high temperature will only result in failure. When potted or boxed, they should be covered with suitable material and kept in a cold frame until the receptacles are well filled with roots.

Lily-of-the-Valley.—In establishments where there is a demand for these flowers during the next few months, one has to rely on the use of retarded crowns. The number of crowns that is likely to be needed to cover a given period should be ordered from the nurseryman and arrangements made for a fortnightly dispatch of batches from the cold storage. Retarded crowns may be had in flower within a month from the time they are received. Place ten or twelve crowns in a six-inch pot, cover them carefully with a deep layer of light, fresh moss, and keep them in a dark place until the growths are about four inches in height, when they may be gradually inured to light, but, at the same time, shading the flowers from bright sunshine; if deemed necessary to hasten growth, the crowns may be subjected to a higher temperature when the latter stage of growth is reached. For later supplies, obtain good crowns which have been specially grown for forcing, and place the same number of crowns in six-inch pots, using any light, sandy soil for this purpose. The soil should be pressed firmly about the roots, and after potting, stand the receptacles in ashes in a cold frame, and afford protection from frost.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Vines.—Pot vines intended for starting at the end of next month or the beginning of December may now be cut back, washed and placed in a position where they may be kept quite cool and sheltered from heavy rain. Any loose surface soil should be removed and when the balls of roots have been made thoroughly moist, they may be top-dressed with good loam well enriched with bone-meal. Early permanent vines may now be pruned and cleansed and loosely tied down until started and ready for tying in position. Washing with Gishurst compound (six ounces to the gallon) should suffice if the vines are young, and if thoroughly performed there should be no necessity for the barbarous practice of divesting the rods of every piece of sound, old bark. If mealy bug has been very prevalent, it will be more difficult to deal with. In this case every piece of loose bark should be removed prior to washing the rods with Gishurst, and filling all holes with pure compound. Cleansing the vines is less difficult than cleaning old vineries, and every part of the house and walls should be scrubbed and lime-washed, and all loose mulching and soil removed aud replaced with new compost.

Succession Vineries.—In these houses the vine foliage is changing from deep green to mottled tints, indicative of ripening. The vines may receive another good washing with the hose to remove any traces of red spider, which has been prevalent. Inside borders should be watched carefully as they often become a shade too dry in the autumn after the vines have been cleared of the crop and the house thrown open. Many people think extreme dryness is favourable to the ripening of the wood, but when roots and leaves feel the lack of water, the soft, crisp feel of the latter, a true index of all being right, is substituted by a harsh texture and rapid leaf-fall, conditions not favourable to a good crop of Grapes the following season. So long as the leaves retain vitality and the house has plenty of air, no grower need be afraid of giving inside borders liberal supplies of water.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Spring Bedding.—With the approach of autumn, no time should be lost in removing the bedding plants immediately their beauty is gone, and having the beds or borders dug over for the reception of bulbs and other subjects for the decoration of the garden in spring. Apart from bulbs, which are the mainstay of spring bedding on a large scale, there are a great many valuable plants for this purpose that can be easily raised from seeds, cuttings, or divisions each year, and which add to the beauty of the spring garden, either as carpets for bulbs or as individual groups. As a carpet for Tulips, various varieties of Aubrietia are very suitable, provided the right Tulip, in the matter of colour, is selected to flower at the time when the Aubrietia is at its best. The variety of Forget-me-not known as Royal Blue is superior to any others; it is well adapted for planting in large beds or borders, and may with advantage be used as a groundwork for white Tulips; or as an effective bed if interplanted with a clear yellow Wallflower, and the outer edge planted with a free-flowering Viola, such as Ardwell Gem or Bullion. Wallflowers and Polyanthuses are always welcome either in masses by themselves, or used as a groundwork for the stronger-growing Narcissi and Tulips. Those that can allow the beds to remain longer than for the average spring bedding subjects may with advantage use some of the dwarf alpine Phloxes as carpets for choice bulbs, choosing such sorts as P. Vivid, P. Nelsonii, P. subulata, and P. divaricata; the last-named is a strong-growing species with lilac-purple flowers and is later flowering than the others. All are free in the production of bloom, and are to be recommended for this purpose. A pretty bed for early summer consists of a good strain of Iceland Poppies interplanted with blue Spanish and English Irises; such a bed gives quite a long season of bloom. There is no lack of easily propagated plants suitable for spring bedding and no end to the various floral combinations that may be employed. One of the chief points to remember is to plant so early as possible, so that both the plants and bulbs may have time to become established before severe weather sets in.

Herbaceous Borders.—Where these are to be replanted this autumn they should be gone over now and all plants carefully labelled; this saves considerable time and worry when the time comes to lift the plants preparatory to digging the borders. Plants that resent root disturbance should be marked specially, so that they may be left undisturbed.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Rhubarb.—Where the foliage has died down, clumps of Rhubarb required for forcing should be lifted in readiness for placing in the forcing house. Select sound, healthy crowns, and when placing them in the forcing house, work plenty of leaves around the roots.

Chicory.—Roots of Chicory for forcing may be lifted now, the top growths cut away, and the roots inserted in beds or boxes of light, sandy soil. They should soon break into fresh growth if afforded warmth and kept in darkness. Keep the atmosphere moist, but water the roots carefully, using tepid water only.

Onions.—The crop that has been harvested should be examined and any bulbs that appear to be decaying removed. If the bulbs have been well ripened they may now be placed in the store-room and laid on shelves or roped and hung from the rafters. It is important that the room in which Onions are wintered should be dry.

Beetroot.—Early-sown Beetroots should be lifted, cleared of their leaves, and the roots stored in sand or ashes, preferably out-of-doors. Should the weather be frosty, provide a thick covering of straw or other protective material. The roots of late-sown Beet may remain in the ground for a few weeks yet; if left throughout the winter, the roots will develop a flat, earthy flavour.

Parsley.—Now that frosts are imminent, means should be taken to protect this popular herb so that fresh supplies of leaves may be obtained over a prolonged period. Long, thin boards joined together in the shape of a Λ, form a very suitable protective covering to place over the lines at night, or mats laid on suitable supports are also admirable for this purpose.

Carrots.—Any fully-grown Carrots still in the ground should be lifted and stored in sand. If left in the ground many of the roots may crack and decay. Late-sown crops should be kept free from weeds, and the hoe worked between the lines to keep the soil surface open.

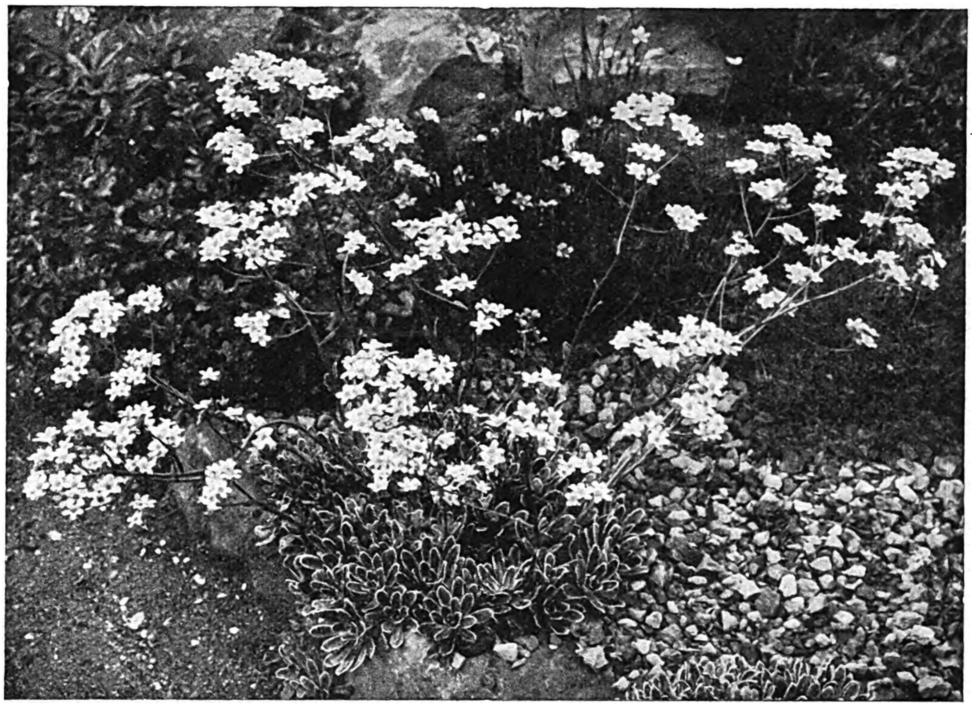

FIG. 149.—SAXIFRAGA KOLENATIANA
(see p. 322.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Lifting Dahlias, etc.—When cut down by frost the Dahlias should be lifted carefully and the tops cut back to nine or ten inches. Dry the tubers moderately in a warm place, and then store them in a cool, frost-proof shed, plunging them preferably in dry sand, Cocoanut fibre or similar material. All plants likely to be destroyed by frost should now be lifted and placed in frames; Lobelia cardinalis, Salvia patens, and all the best varieties of Montbretia are liable to be destroyed if left unprotected. They should be lifted and placed in frames, either in boxes of light soil or in beds. A little frost will not harm them, provided they are not allowed to become damp at any time.

Planting Small Fruits: Raspberries.—Before the ground becomes sodden, any planting of small fruits should be pushed forward. Canes of Raspberries for new plantations should be young and not too vigorous. The ground for all small fruits should be well cultivated and enriched with liberal dressings of farmyard manure well incorporated. The soil should be allowed to settle for a time before planting. Raspberries are best grown against wire fences five to six feet in height, to which the canes are fastened, but these need not be erected at the time of planting, as the young canes should be severely cut back in spring to induce strong growth the first year, on which the future success of the plot depends. Two feet is sufficient space between the plants, and the rows may be five or six feet apart, according to the variety planted. Superlative, one of the best varieties, does well at five feet, but, unfortunately, it has not a robust constitution and dies out in a few years. Baumforth's Seedling is almost as good for cropping and quality of fruits, and seems to be more lasting, but requires the greater distance. Raspberries would appear to prefer light shade and cool conditions at the roots. In exposed situations, Raspberries may be grown in clumps, four to five feet apart, the canes being arched over and tied together, forming a series of hoops. This plan has something in its favour in that the young growths are clear of the fruiting canes during the summer.

Brambles.—These are quite a profitable crop in certain seasons. They should be treated as for Raspberries, that is, they should be grown on wire fences, but require a greater distance apart, owing to the vigour they show on cultivated ground.

Loganberries.—These give the best results in the north if grown against a low wall, in a sunny aspect, treating them as for Raspberries and Brambles in all other respects.

Black Currants.—These also do well in a cool, shady place. In making a permanent row or plot, a good plan is to put in three one-year-old plants, one foot apart, in a triangle, the groups being at least five feet from centre to centre. Black Currants should be pruned hard back the first year to encourage a strong break both above and below the ground, after which they give little trouble.

Gooseberries and Red Currants.—These differ from Black Currants in that a clear stem is advisable, suckers being undesirable. If bought from a nursery, plants should be chosen with about six inches of clear stem, as if longer, the plants are liable to be blown about by the wind. Not less than five or six feet both ways should be allowed between the permanent plants, and bushes not more than three years old should be planted. Avoid deep planting, it being advantageous to keep the roots of all fruit trees and bushes near the soil surface.

ALPINE GARDEN.

SAXIFRAGA KOLENATIANA.

The Aizoon, or Encrusted Saxifrages, have provided us with many gems for the rock garden, for none of them is difficult to accommodate and all are especially valuable on account of their silver-encrusted rosettes of foliage and dainty sprays of blossom. No rock garden is complete without a selection of them, ranging from the diminutive forms of S. aizoon to the giant S. Cotyledon and much-prized S. longifolia. They are also grand subjects for pot or pan culture in the alpine house.

Whereas the majority of the members of this group of Saxifrages have white flowers, those of S. Kolenatiana (Fig. 149), which by some authorities is regarded as a variety of S. cartilaginea, are of an attractive shade of pale pink, dark red in the bud, and borne in dainty sprays on red-tinted stems. Therefore, this Saxifrage is especially worthy of a place, in a sunny position or in a rock crevice, where it will form an ever increasing mound of closely-packed, encrusted rosettes of foliage which, in winter, becomes shaded with red. *F.*

ACTINELLA SCAPOSA.

When on a visit to Kew Gardens about the end of July, I came upon this plant in bloom in the rock garden, and it appeared to me as a very desirable rock garden plant for late summer effect.

Actinella scaposa is stated to be a good perennial, but its appearance gives the impression that it would not be long-lived. However, it is worth a place for its foliage alone, for the narrow leaves, which form a close clump, are about four inches long and furnished with silvery down. The Hieracium-like flowers, which unfold from very silky-haired buds, on red-tinted stems one foot or so in height, are very striking for the golden-yellow ray florets encircle a close mass of orange disc florets, the whole being about one-and-a-quarter inch wide.

A. scaposa is a North American plant, and in English rock gardens would appear to require a fairly warm, sunny position and open, light, loamy soil; possibly, on account of its extreme downiness, it may need protection from damp, in the form of a sheet of glass overhead during the winter.

There are, apparently, one or two other Actinellas suitable for culture on the rock garden, one book of reference stating that A. grandiflora the Pigmy Sunflower, and a native of Colorado, is the best.

A. scaposa does not appear to be in general cultivation in this country, and it is not listed in any of the catalogues of the leading alpine plant specialists. I have in my possession, so one can only hope that it will become available in the future. *M. W.*

TREES AND SHRUBS.

LONICERA NITIDA.

During recent years much has been heard of Lonicera nitida, and it has for some time been quoted in quantity by nurserymen who recommend it as a hedge plant. This species is certainly very useful for such a purpose in mild localities, although the clipping that is necessary somewhat destroys its natural grace. Those who contemplate using this Honeysuckle as a hedge plant should, however, be very sure of its hardiness in their particular district, and they would be well advised to grow it for some time as a specimen shrub in their gardens before definitely deciding to use it for a hedge, especially if the area to be enclosed is of any great extent. It is really surprising that a comparatively recent introduction from China should have so quickly gained popularity as to be offered by the hundred or by the thousand.

Lonicera nitida is an evergreen, forming a dense, although graceful bush of some three or four feet high (possibly more) and as much through. The young growths are at first erect, but as they grow older they arch gracefully over and lend a weeping habit to the shrub. The small, thick, glossy, ovate or heart-shaped leaves are opposite and close together on the stems, which are purplish in the young state and turn brown and woody later. Cream-coloured flowers are produced on the leaf-axils; they are fragrant, but of no great beauty and are followed by purplish berries.

Among many other plants from China we owe this species to Mr. E. H. Wilson, who introduced it from Szechuan and Yunnan some twenty years ago. Under natural conditions it grows at altitudes between 4,500 and 7,000 feet, and although not completely hardy in exposed localities in this country, it will withstand several degrees of frost. The young shoots, however, are apt to be nipped by severe late spring frosts. Propagation may be effected by seeds if they are formed or, failing this, by cuttings of young wood, taken with a heel of the older wood and placed in slight bottom heat in late summer, or by cuttings of firm, ripened wood, simply inserted in sandy soil in frames or under hand-lights or cloches out-of-doors. *L. C.*

INDOOR PLANTS.

CALOTHAMNUS QUADRIFIDUS.

This quaint but lovely plant from west Australia was introduced so long ago as 1803, and is so distinct as to merit a place in all good collections of greenhouse plants. It attains a height of about three feet, with spreading branches; the ovate leaves possess numerous minute, glandular protuberances, imparting to them a measure of roughness, and in colour they are an attractive shade of fresh, bright green. The flowers are scarlet, axillary and solitary, each resembling a cluster of brilliant feathers.

This greenhouse evergreen shrub succeeds in a mixture of peat, loam and sand, and thrives under treatment usually afforded Callistemons and Metrosideros; it is a member of the Natural Order Myrtaceae, and is easily propagated by cuttings. C. quadrifidus is figured in *Bot. Mag.*, t. 1,506, and there is also a good illustration of it in Loddige's *Botanical Cabinet*, t. 737.

DAEDALACANTHUS NERVOSUS.

One of the finest of blue-flowered plants for a warm house, Daedalacanthus nervosus is not difficult to grow in a mixture of equal parts peat, leaf-mould and loam, with sufficient sand to ensure porosity; cuttings root readily in the spring and grow rapidly into plants of appreciable size. It is important to grow them so near the glass as possible, thus suppressing any tendency to elongated growth.

The flowers are produced in winter and early spring, at a season when they should be particularly welcome; the plants should be pruned back after flowering and, for a time, kept somewhat dry, after which they may be potted on to form good specimens for another season.

The flowers are a good bright blue, the surface of the dark green, broadly ovate leaves is somewhat wrinkled, and the average height of the plant is about two feet. This, the most popular species of a genus allied to Eranthemum was introduced from the East Indies in 1796. *Ralph E. Arnold.*

HARDY FLOWER BORDER.

THE ARENDSII HYBRID PHLOXES.

Although introduced several years ago, the Arendsii Phloxes produced by the raiser of the grand Arendsii Astilbes, make their way slowly into favour. They are hybrids between Perry's variety of P. divaricata and P. decussata, and are of much value because of their long season of flowering, while they are useful either for the border or rock garden. Their height varies a little, but those I have grown are rather over a foot high. These hybrids have not the shapely spikes and trusses of P. decussata, but they are highly pleasing plants, with their compact habit and many blooms, which come in succession for a long time. There are now a fair number in cultivation, and were one disposed to criticise severely one would state that several of them are very much alike. Shades of lilac and blue predominate, but the range of colouring is gradually being enlarged and we shall probably have some more distinct varieties in due time. These Arendsii Phloxes grow in ordinary fertile soil, and are best, I think, in sun.

Of those with lilac or blue flowers, the following may be mentioned. Amanda, with a dark centre on lilac ground, and dwarf habit; Charlotte, which has a deep blue eye and a lavender ground—an excellent variety; Emmy, one of the tallest, and in some soils two feet high, lilac, with a deeper eye—its height of nearly two feet renders it more suitable for the border than the rock garden; Lisbeth, with white flowers, tinged with lilac on the exterior; and Bertha, which marks a break from the others, as the white blooms are striped with lilac. Inge is another variety with some distinctiveness, as the flowers are of a pleasing tone of pink; and Elisabeth is white with the outside of the petals tinged with lilac.

These Arendsii Phloxes do not create such an imposing display as the varieties of P. decussata, but they may well repay the consideration of those who are not wedded to one particular type of flower.

LYCHNIS VISCARIA VAR. SPLENDENS PLENA.

This old plant in gardens appears to fall greatly out of cultivation for a time, but every now and again fresh interest is evident in its good qualities, and it again finds favour among growers of hardy flowers. Its main drawback seems to be that it requires propagation by division or cuttings at intervals, but good plants live for many years without this, if care is taken to place some fresh soil about them. Otherwise it may be lifted and replanted a little deeper every two or three years. It is well worth even more trouble than this, as it is a very striking plant near the front of the border or in a rock garden, although I consider that the latter is hardly the place for it.

It forms low tufts of narrow leaves, from which arise stems, varying, according to the lists, from nine to twelve inches high, but, as I have found, frequently exceeding this. My plants, in good loam, generally attain fifteen to eighteen inches in stature. The stems, which require support, bear a number of very double flowers of a bright magenta-rose. The colour is not so aggressive as might be surmised from this, and is quite good.

This Lychnis is a development of the finest form of the Alpine Catchfly. It likes a good loam, and should, preferably, have a sunny position, although this is not necessary. It is easily increased by division of large plants or by cuttings. It flowers from May onwards for some time. *S. Arnott.*

CEDRONELLA CANA.

Among the by no means numerous subjects of moderate height which provide colouring for the front of the herbaceous border during the latter part of summer and in early autumn, is Cedronella cana, a handsome Labiate of rich colouring.

This relative of the so-called Balm of Gilead—C. triphylla, a sub-shrubby species from the Canary Islands, and valued for its odour—hails from New Mexico, and was introduced in 1851; it is figured in the *Bot. Mag.*, t. 4,618.

The Hoary-leaved Cedronella, as it is sometimes termed, forms a much-branched, bushy clump up to about one-and-a-half foot high, its slender, square stems being clothed with narrow and entire, small leaves, the uppermost ones being hoary, and above these are produced the densely whorled spikes of flowers, which are a rich purplish-rose, with darker calyces, and are produced very freely, the whole plant becoming a close mound of bloom. It becomes semi-shrubby at the base but, although, apparently, quite hardy, is not always long-lived; however, it may be increased quite readily by means of cuttings of the young growths. It is not particular in the matter of soil, for it flourishes in any ordinary border medium that is not of too heavy a nature.

The generic name, Cedronella, denotes "a little Cedar," in reference to the odour of C. triphylla. *Kent.*

PLANT VARIATIONS.

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

Preliminary Remarks and Definitions.

The appearance of variations—commonly called sports—whether of habit, shape or colour of leaf, flower or fruit, never fails to create interest among horticulturists, botanists and scientists, and the following account of chimaeras due to hybridisation, grafting or variegation, is an attempt to explain, as simply as possible, some of the phenomena met with among plants. It is hoped that these notes may be the means of inducing others to contribute further observations on this subject. Specimens of interesting cases of sporting would be welcomed at the John Innes Horticultural Institution for comparison and for further study.

For a more technical exposition of this branch of genetical work, by various writers, the reader should consult the books and periodicals which will be mentioned at the end of this contribution.

During recent years, a large number of observations have been made by geneticists and others on the occurrence of bud variations and variegation, with the object of analysing and co-ordinating the different kinds, and of discovering, if possible, the cause and mechanism of their origin.

Both in horticultural and genetical literature, the words "sport" and "mutation" have been used loosely so as to cover the appearance of any new form, whether coming from seed, or as a bud sport directly from the plant.

It is well-known that seedlings of hybrid origin will show extreme variability, the result of recombination in all sorts of ways of the different elements of the parents, but with this type of seminal segregation the present article is not concerned.

Somatic segregation, or bud sporting, is of frequent occurrence in plants, due to some change which has taken place in the body cells of a plant, giving rise to a shoot bearing either leaves, flowers or fruits which differ from the normal. This change, by which two genetically dissimilar cells are produced as a result of cell division, may be caused by some change in the nuclear constituents, or, in the case of plants which have a periclinal structure, by somatic rearrangement of the extra nuclear constituents of the cells, like the plastids. As a rule, such examples of somatic segregation are more commonly met with in plants of hybrid origin.

Below will be found some particulars of a few plants that show somatic segregation or bud-sporting :—

Flower Sports.

Striped flowers of different colours often occur on the same plant. Most of these are of hybrid origin, and frequently give rise to whole branches of individual flowers that are self-coloured, *i.e.*, pink, red, scarlet, magenta or white, caused by a sort of somatic segregation or separating out of the various colours found on such plants.

Many cases have been recorded of a whole plant, or a single branch or bud, suddenly producing flowers different to the proper type in colour, form, size, doubleness, or other character. Half of the flower, or a single segment, sometimes changes colour. A double, yellow-flowered form of Althaea rosea (Hollyhock), turned one year into a pure white, single kind. Subsequently, some double-yellow flowers appeared in the midst of the single, white kind (*Gard. Chron.*, 1845, p. 475.)

Helianthemum vulgare var. Mrs. Earle, double red, often gives a double, yellow-flowered sport called Cumberland Belle.

Other examples are: Callistephus sinensis (China Aster) and Antirrhinum majus (striped strain); Azalea indica var. variegata, which has produced two distinct varieties viz., Gledstanesii and lateritia (*Gard. Chron.*, 1844, p. 337); Bouvardia, several varieties (see Root Sports); Camellia, many varieties; Chrysanthemums, a large number of garden varieties of which have arisen as bud sports; Cheiranthus Cheiri (Wallflower); Daboecia polifolia var. bicolor, which sometimes bears red, white, and some flowers red and white (Fig. 150); Dahlias, many of the fancy and striped varieties sport into self colours, *e.g.*, Union Jack; Dianthus (Carnations and Pinks), Gladiolus (see below), Fuchsia, Geranium pratense var. striatum, Hyacinth, Hibiscus, Myosotis alpestris (Star of Zurich and Weirleigh Surprise), Matthiola (Stock), Mirabilis, Oenothera, Petunia, Papaver orientale, P. Rhoeas, Pelargonium, Phlox, Primula sinensis, Rosa Mundi and York and Lancaster Rose, Tulip, Tagetes (French Marigold), Verbena, Vinca minor, and Viola.

In 1915 there appeared in a row of Gladiolus The Bride, a single flower-stem bearing partly red and partly white flowers. This form of Gladiolus is a white variety of G. Colvillei, a red-flowered kind, and doubtless originated as a seed or bud mutation. Gladiolus Colvillei is a hybrid between G. cardinalis and G. tristis, which has white or yellowish flowers.

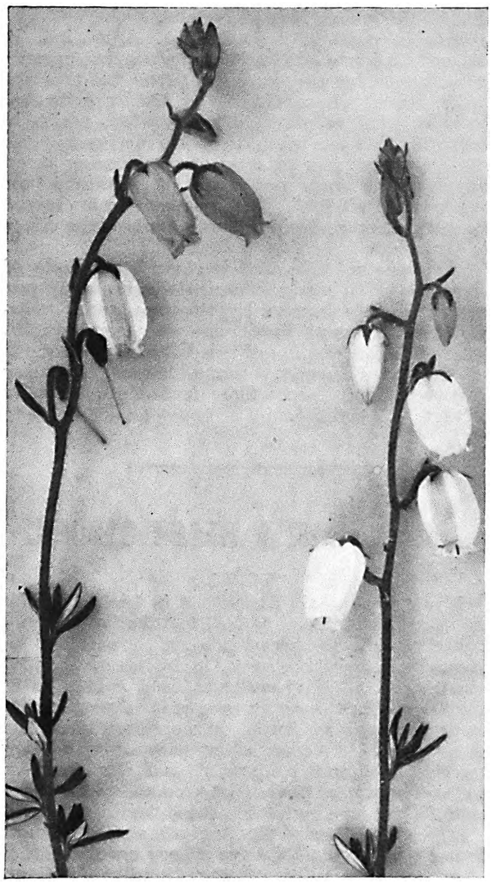

FIG. 150.—DABOECIA POLIFOLIA VAR. BICOLOR.

Impatiens Holstii, a scarlet-flowered plant, has produced branches with pink flowers and some of an intermediate colour.

Rose Sports.

Many garden varieties of Roses have originated as bud sports from other sorts. Only a few need be mentioned (fuller lists may be found in catalogues and books) :—York and Lancaster (Rosa damascena variegata); Moss Rose (Rosa centifolia muscosa) originated as a sport; sometimes a white Moss Rose will sport a pink-flowered variety of different form and destitute of mossy appendages; Madame Edouard Herriot has given several sports; Gloire de Dijon has given a pink variety (*Jnl. Royal Horticultural Society*, 1877, Vol. 4, p. 153); Queen Alexandra gave a sport called Charming Princess; Catherine Mermet, a pink variety, gave Maid of Honour, a deep pink, and Muriel Grahame, a pale pink; Dorothy Perkins gave White Dorothy and Lady Godiva, soft flesh-pink; Ophelia gave Madame Butterfly; Madame Butterfly gave Lady Sylvia, and Orleans Rose has given several colour forms.

Fruit Sports.

Peach and Nectarine.

Bud variations are frequently exhibited in the fruit. Many Peaches (Prunus Persica) have produced buds, which, when developed into branches, have yielded Nectarines (Prunus Persica var. laevis). Six named Peaches and some unnamed varieties have produced several varieties of Nectarines. Sometimes the fruit produced has been in part a Nectarine and in part a Peach. Nectarines produced in this way have reproduced themselves from seeds. Peaches have also produced Nectarines from seeds. The seeds of Nectarines occasionally produce Peaches.

The Peach Grosse Mignonne, produced at Montreuil, from a sporting branch, the Grosse Mignonne Tardive, a most excellent variety, which ripens a fortnight later than the parent plant, and is equally good. (*Gard. Chron.*, 1854, p. 821; 1852, p. 821; and 1864, p. 1,251).

Plum (Prunus domestica) and Cherry (P. Cerasus).

Mr. A. Knight stated that Yellow Magnum Bonum Plum, a tree forty years old, which had always borne ordinary fruits, produced a branch which yielded Red Magnum Bonum (*Trans. Hort. Soc.*, Vol. 2, p. 160).

Mr. Rivers, January, 1863, stated that a single tree out of 400 to 500 trees of Early Prolific, a purple kind, produced, when about ten years old, bright, yellow fruits (*Gard. Chron.*, 1863, p. 27).

Coe's Golden Drop has given, as sports, Coe's Violet and Crimson Drop. These sports are fairly constant, but occasionally revert to type.

Mr. Knight has recorded (*Trans. Hort. Soc.*, Vol. 2, p. 160) the case of a branch of a May Duke Cherry which, although certainly never grafted, always produced fruits, more oblong and ripening later than the fruits of the other branches.

Grape (Vitis vinifera).

The black or purple Frontignan Grape in one case produced during two successive years (and no doubt permanently) spurs which bore white Frontignan Grapes. In another case, on the same footstalk, the lower berries were well-coloured black Frontignan, some white and one streaked berry. In another kind, both black and amber-coloured Grapes were produced in the same cluster.

Other variations have been recorded (*Gard. Chron.*, 1852, p. 629; 1856, p. 648; 1864, p. 986; 1866, p. 970).

Gooseberry and Currants.

Dr. Lindley (*Gard. Chron.*, 1855, pp. 597, 612), describes a Gooseberry bush having four kinds of berries—hairy and red; smooth, small and red; green; yellow, tinged with buff. Mr. Laxton has seen a Red Warrington bearing both red and yellow fruits on the same branch. Gooseberry Helen Holmes has striped fruits.

The Champagne variety of Red Currant (Ribes rubrum) produced, during fourteen years, on separate branches and mingled on the same branch, berries of the red, white and Champagne kinds. (*Gard. Chron.*, 1842, p. 873; 1855, p. 646; also p. 876.)

A Red Currant bush about ten years old produced, near the summit, five white berries, and, lower down, among the red berries, one berry half red and half white. (*Gard. Chron.*, 1844, p. 87).

A white-fruited Currant has given the red-fruited kind.

PEAR AND APPLE.

Some fruit variations have been noticed on the same tree of a Pear. Several colour forms of Apple have originated as bud sports, *e.g.*, Crimson Bramley, from Bramley's Seedling, and Crimson Cox from Cox's Orange Pippin. *A. Hosking, Garden Superintendent, John Innes Horticultural Institute, Merton, Surrey.*

(*To be continued.*)

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

Is there any record of Davidia involucrata having flowered in the open in Scotland? I do not know whether the three forms of this tree are now reckoned as species or varieties; nor can I confidently affirm to which form the trees here belong. They are thirty feet high and pictures of vigorous growth, but they have never borne a single blossom, although I have seen specimens in the south of England, no larger than ours, well furnished with conspicuous white bracts and ripening plenty of seeds.

I begin to suspect that Davidia demands sunshine of a more stimulating quality than it gets here to induce it to flower. If so, we must mournfully relegate it to the same category as the Virginian Fringe Tree (Chionanthus virginica) and Clerodendron trichotomum. The Fringe Tree never gives us more than a niggardly allowance of its white panicles, and the Clerodendron, although crowded each August with ruddy bracts, delays so late in opening the flowers contained therein that we never have anything approaching the display such as has filled me with envy at Abbotsbury and similar sun-baked places. Clerodendron foetidum is even later in flowering, and it is only about once in five years that we are accorded the privilege that we are enjoying this year of admiring its corymbs of bright rose, fragrant flowers. But they are well worth waiting for.

Among herbaceous plants there are three species which excel all others in my experience for prolonged season of bloom. Here we treat Echium plantagineum as an annual, for although it is a perennial from southern Europe, it seldom survives our drenching winters in a condition to do itself justice. Sown in the open in early spring, it begins to open its long sprays of purple flowers in June, and never desists until these are quenched by frost. This plant claims ample room, growing three feet high and as much across, for it inclines to sprawl. Nothing in our ragged and untidy borders claims more frequent attention from visitors; the plants are now—in mid-October—still well set with bloom, as they have been throughout the summer.

Geum Borisii, which we are now told is not the true hybrid named by ex-King Ferdinand of Bulgaria after his grandson, the present King, opened its first flowers in May, and still carries on the long succession of rich, but soft orange discs which usually outlast Christmastide.

The third in this trio of long-flowering species is the Mexican Erigeron mucronatus, formerly known as Vittadenia triloba. It is not a fit subject for the mixed border, for the flowers which it produces in countless profusion resemble the common Daisy so nearly as to give the impression of careless weeding. Nor is it safe to admit it to the company of choice plants in the rock garden, for it spreads so fast by seeds and root runners that it soon obliterates less vigorous neighbours. But when established on some old wall it will furnish it with a cheerful drapery of blossom, lasting throughout summer and autumn. Those who have travelled by road from Cintra to Lisbon can hardly have failed to notice how gracefully the walls on either side of that road are clad with this pretty Composite, probably an escape from the famous garden at Cintra.

Now that the flame of Torch Lilies—Kniphofias—is extinguished, it is time to note what colour remains in the borders. Of Michaelmas Daisies we have discarded most varieties, because, being short-handed, it is troublesome to control their invasive habit; but Aster Amellus var. King George is indispensable with its rich purple bloom, for which a fine contrast is at hand in Rudbeckia speciosa (syn. Newmanni). One often sees this plant far short of its best, for it is a greedy feeder; but it responds to a generous diet with a crowd of golden blossom during many autumn weeks.

For intense blue, there is nothing at this season to rival, or even approach, Gentiana sino-ornata; a plant of simplest requirement, seeming to make itself at home almost anywhere, although I do not know how it may fare on chalk. Blue also, but of a subdued purplish hue, are the flowers of Aconitum Fischeri, borne in profusion during October. It never shows to greater advantage than when planted out in woodland, especially when arranged as a contrast to the autumnal carmine and saffron of Cercidiphyllum japonicum or the intense crimson of Vaccinium corymbosum. Where rabbits abound, this Aconite requires protection when first planted, for they attack it at once out of sheer cussedness; but once it is established they leave it severely alone, for, like the rest of the genus, it is poisonous.

Senecio pulcher, a native of Argentina, is more fastidious; and as it starts late into growth it is apt to be uprooted when the borders are forked over, or smothered by lustier growths. It is entitled to all kindly attention, which it repays in October when, from among its smooth, radical leaves it sends up stems bearing large flowers with magenta rays surrounding an orange-yellow disc. The colour scheme might be deemed excruciating; but somehow the effect is excellent.

No more notable addition has been made of recent years to hardy autumnal flowers than that beautiful Lily known by the ponderous polysyllables Lilium philippinense var. formosanum. There is a fine display of this Lily in the grounds of Castle Kennedy, many stems standing between four and five feet high. *Herbert Maxwell, Monreith.*

NOTES FROM A WELSH GARDEN.

EVEN if there is little that is fresh to write of autumn colour, "Old October's" kindly contributions to our year's round will not be passed unnoticed; and, in spite of gloomy predictions to the contrary, leaf colour is as brilliant as I can ever remember it. An unusually bountiful crop of fruits on berrying trees and shrubs adds a fuller, riper note of well-being to this autumnal splendour, and the weather, here, at any rate, has not been so rude as to speed unduly the passing of the most fleeting of tints.

The leaf-colour of the Azaleas, a predominant feature in a small garden where shrubs rather than trees prevail, is exceptionally brilliant. The hybrids with their glossier foliage, and a few species such as A. Vayesi, are even more gorgeous than the old yellow Azalea, which is saying much. Cotoneasters are all so good that one hesitates to make comparisons. But C. salicifolia var. floccosa, given sufficient space to display the unrivalled elegance of its slender, arching branches, must always rank very high among the evergreen kinds at this season. Moreover, the scarlet fruits which adorn its long, whip-lash twigs do not seem to be quite so irresistible to birds as do those of some others. Another shrub which more than holds its own among many rivals is Vaccinium corybosum. Its large leaves are a blend of sumptuous hues, plum-purple and bronze, crimson and orange, among which are clusters of glaucous-blue fruits the size of Currants. Indeed, most of the Vacciniums give vivid touches of colour, as do their allies, the Gaylussacias, but these latter do not seem to be so popular as they might be. Diminutive as it is and useful as carpeter for any of these, as well as Ericaceous plants, that tiny Raspberry, Rubus arcticus, glows with a blend of orange-scarlet and crimson so intense that it will make itself noticed among the bigger things.

The Exochordas seldom fail to end in a shower of most delicate yellow, and in that tint a Swedish Birch, Betula verrucosa var. dalecarlica, has been excellent. This specimen, still in its youth, was put in to provide light shade for a few Primulas and other things as well as for its own matchless grace. A more elegant and refined sapling it would not be easy to find, even among its own beautiful family, the weeping branches being very slender and daintily poised while the comparatively large leaves are lobed almost to the mid-rib. Although scarcely a dozen feet in height, the bark of this youngster is already getting white. The Judas Tree is another which turns a good clear yellow, which looks remarkably well against the sombre green of a Lawson Cypress. The former, by the way, has fruited with the greatest freedom this season, and the pods promise to ripen successfully.

That unseasonable activity which one feared would follow the break-up of the drought has apparently been warded-off by the rapid fall in temperature which accompanied the rain. But this has not been enough to deter that fine shrub, Desfontainea spinosa, from producing a good late crop of bloom. Its fiery crimson-scarlet and yellow trumpets happen to harmonise very sympathetically with the prevailing tone of the hour, as do the warm yellows of some of the shrubby Potentillas, notably P. fruticosa var. arbuscula. That useful old plant, Schizostylis coccinea, does the same thing with remarkable success, a bold mass within sight of the flaming foliage of some Aronias (Pyrus arbutifolia) and a Liquidambar being very striking. Even the beautiful variety, Mrs Hegarty, is warm enough in the tone of its glossy pink and golden stamens to be in tune with the season. But in this matter of harmonious association nothing of an herbaceous kind is quite so telling as Kniphofia Nelsonii. Several clumps of this adorable little "Poker" have been in flower since September, their finely-pointed, orange-scarlet spires being so restrained in tone, yet so richly glowing, that they seem to radiate the very essence of autumn's most precious vintage.

Viewed in the light of the above, Gentian sino-ornata always appears to me to be a little exotic. There is to my mind in this wholly admirable plant a note so unyielding in its insistance on one's attention that its success comes near to being a triumph of sheer force. It trumpets defiance at the sweetness of old associations and demands the field to itself. If it is the finest Gentian for the every-day gardener ever introduced, "close bosom-friend of the maturing sun" it can never be, since its arrogant colour must clang a discord in October's requiem. Even so, one can never be without it, but it is always possible to plant it in straight rows in a rectangular bed which it will thoroughly enjoy converting into a solid slab of its imperious blue. That, at any rate, is how a famous Sussex gardener satisfies its tempestuous spirit!

Schizocodon soldanelloides, which generally yields a few blooms at this season, has put up an exceptionally good show of its pretty, deeply-fringed, rose-pink bells. In the cool, partly-shaded spot occupied by this choice little plant is Saxifrage Fortunei, a useful late-blossomer and one by no means unattractive in leaf and bloom. There are still some sprays of rosy-white on Astilbe simplicifolia; Spiraea digitata var. nana is not less persistent with its pink crests of blossom, and Parochetus communis is dappled with hundreds of its Pea-shaped blossoms in a soft, rich blue. The only trouble with this delightful herb is that it either sulks or ramps. Moderation it disdains. But of the two forms I possess, one has flowers of a much deeper blue without the little flare of white on the upper petal, and with the parallel leaf-markings more uniform and stedfast. This one has nothing like the tremendous vigour of the other. What it lacks is a little more, when it would be a valuable acquisition where space is limited.

Heaths have had a trying season on these parched slopes, all the mid-season kinds being weak in blossom and passing off quickly. The best of the Cornish Heaths, notably E. vagans varieties kevernensis, Lyonesse and Mrs. D. F. Maxwell, have fared better, and some plants of the E. Tetralix class, being in moister soil, have flowered abundantly since June. The excellent E. T. var. mollis and E. hybrida var. H. Maxwell are among these, the latter being much like the older E. Watsonii. E. ciliaris was killed to the base last winter, and did not recover soon enough to bloom successfully, but it says much for that fine shrub, Daboecia polifolia, that, although all varieties had to be cut back in spring to the ground level, the loss was so quickly made good that the plants have flowered well. A group of the typical D. polifolia with large, well-rounded bells of a gentle lavender, has been delightful enough to impress upon one the fact that we are sometimes too apt to allow colour forms to supercede the type. Mr. Ingwersen, who sent me these plants, tells me that they are of an Irish strain. Erica ciliaris var. Maweana is a late blossomer of exceptional quality and distinction, and at this season the rosy-pink flowers on the soft, moss-green foliage of E. Williamsii are always pleasing. Some time ago I alluded in these columns to a late-flowering form of Calluna vulgaris which I brought from southern France, where it flowers all the winter. This is now in its third season, and although one fully expected it to revert and fall into line with other Lings, it still retains its determination to blossom in October, continuing until December in the absence of severe frost. Its brightly-coloured spikes and vivid green are now a strange contrast to the shrivelled blossoms of others of its kind. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

BULB GARDEN.

LILIUM PHILIPPINENSE VAR. FORMOSANUM.

As there seems some confusion about the number of flowers on one stem of Lilium philippinense var. formosanum, "Price's variety," I am sending a photograph of some plants I raised from seeds. The seeds were kindly sent me by Mr. James, who lives in north London. The tall plants are in their second season of flowering, and the largest number of blooms I had on one stem was fourteen; the most prominent shown in the illustration (Fig. 148). Mr. James informed me this Lily would flower fourteen months from the time of sowing the seeds. I expect it would if kept in pots, but I planted mine out from three-inch pots about fifteen months ago. The seeds germinated very freely; the dwarfer plants are from a later sowing, which I hope next season will be as tall and as free-flowering as the others. All withstood 25° of frost last winter. This is a fine Lilium, and its scent is charming. *H. Kempshall, Abbotsbury Garden, Weymouth.*

MODERN DELPHINIUMS.

DURING the past quarter-of-a-century the perennial Larkspur has been moving steadily towards perfection. Each year one wonders if any further progress is possible and yet one finds some new combinations of shades hitherto undreamed of. In addition to the numerous shades of blue, purple and mauve, a tinge of red is creeping into several of the modern varieties, thus hinting at the possibility of a still further extension in the range of colour. A noteworthy feature in up-to-date sorts is that of the wonderful jewel-like centres of the flowers, which florists call "eyes." These often form striking contrasts to the background on which they are set, and they may be pure white, creamy-white, jet black or brown. The latter often assume the appearance of a cluster of bees settling on the flower, and such sorts are described as "bee-eyed." Improvement is, likewise, noticed in the size and form of the individual flowers. I measured some "pips" last summer, and they were easily three-and-a-half inches in diameter.

As a border plant the Delphinium can hardly be excelled. The plants come into flower early in June, and if the primary spikes are cut before they are allowed to set seeds the dainty lateral spikes carry the flowering period well into August. The plants may be put into the ground either in the autumn or spring as circumstances dictate. In very heavy soils spring planting is perhaps advisable, although where the soil is well-drained, I do not think there is much in it. The culture of these plants is practically the same as that of most border aristocrats, the chief desideratum being a deeply-cultivated and generously manured soil.

The reason why amateur growers often produce better spikes than the nurseryman is that they are able to give that individual attention which the trade grower may not find time for. The professional grower spends his energies in the production of a saleable stock of new and noteworthy types. The raising of seedlings is a fascinating occupation (Fig. 151).

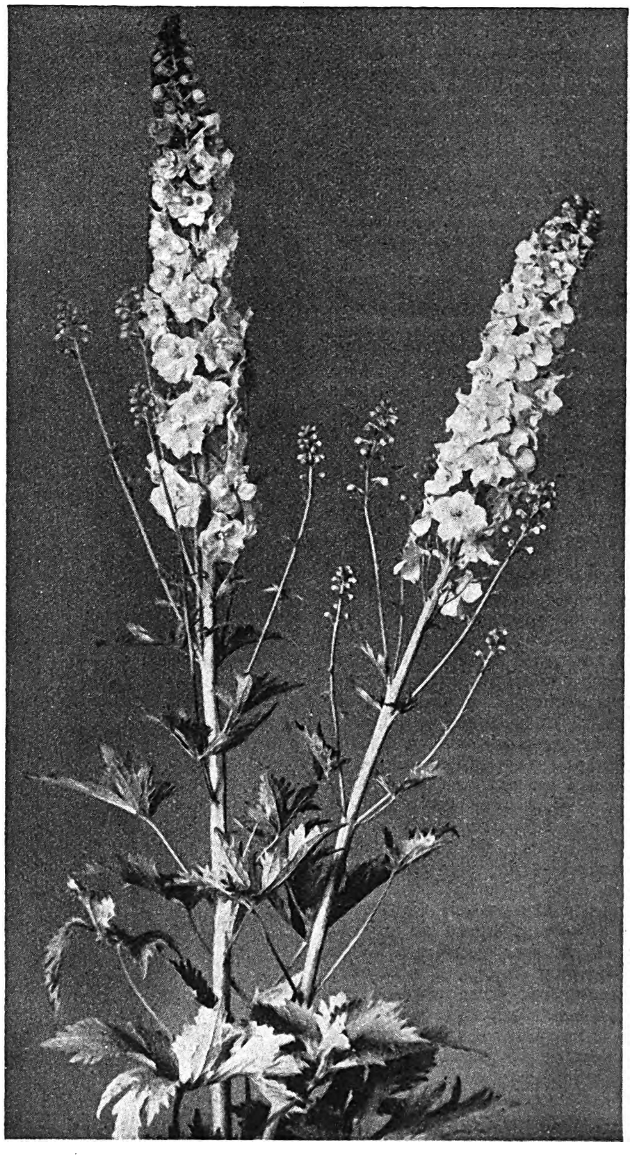

FIG. 151.—A GOOD TYPE OF SEEDLING DELPHINIUM.

The chief enemies of Delphiniums are slugs and snails, and these pests should be guarded against in the spring when the young shoots are appearing above ground. Some kinds seem to be susceptible to mildew, but those which show this tendency are generally excluded from commerce, so that this disease may not yet be regarded as a serious menace.

Among recent novelties which made special appeal to me during the past summer were Mrs. Philip Runciman, reddish-purple and deep blue, large flowers and immense spike; Kate Greenaway, a porcelain-blue variety with crinkled sepals; Dark Lantern, deep violet-blue, creamy-yellow eye; Red Dawn, deep purple, tinged red, white eye; Happiness, pure light blue, white eye, long slender spike; Knight of Somerset, strong gentian-blue, black and creamy eye; Cecil Henderson, bright blue, tinged purple, yellow eye; and Wedding Bells, with lovely mauve-pink edged sky-blue, semi-double flowers and tall spike.

Among older varieties, I regard the following as varieties of outstanding merit. Dusky Monarch, a semi-double variety, light purple with black eye and a branching habit; James William Kelway, deep purple and violet, white eye—this variety is an improvement on King of Delphiniums, the variety which made such a stir when it was exhibited in London some years ago; Kelway's Goliath, deep blue, edged purple, black eye with a yellow fringe; Geraldine Kelway, light azure-blue, white eye; Mrs. James Kelway, pale sky-blue, with a spreading, white eye; Persimmon, still one of the best of the older varieties, light blue, bluish-white eye; Sir Douglas Haig, blue and purple, semi-double, majestic spike; Rev. E. Lascelles, deep purple-blue, spreading white eye; True Blue, an old sort that has retained its popularity, intense blue, black eye; Smoke of War, purplish-violet, tinged red, black eye; Norah Ferguson, pale blue and soft pink, a charming combination; Monarch of All, violet and purple, bee-eyed; and Millicent Blackmore, a fine variety with flowers of a pleasing blend of blue and mauve. *H. Greaves, F.L.S., Minehead.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London! or by telephone to Temple Bar.* 7818.

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXIII.—Storm and Distress.

After the deluge on October 1, which witnessed also the conquest of Polon, the weather began to improve steadily for three days, sunshine and showers playing hide-and-seek with each other. And then came typhoon! At last I was able to take my seeds up to the grassy ridge, five minutes' scramble from our camp. This look-out ridge faced south, and was quite dry when our camp was still wringing wet; when it was fine, sun and wind combined to warm it and sometimes we sat up there and watched the mist sweeping over the forested saddle in which our camp lay, and avoiding us altogether. Thus I soon had all the Primula seeds dried and packed—they now numbered five species.

The sky was perfectly clear when October 3 dawned; but the clouds gathered so quickly that by ten o'clock it was raining. There followed an April-showery day, and a stormy sunset, but after dinner the stars were shining again and our hopes ran high. The next day was finer, and at sunset we took our evening walk to the look-out, to enjoy the panoramic landscape. Everything looked ridiculously near. Right in front lay the deep ravine which separated us from Chibaon, where we had halted for twelve days in April; its lowest slopes, 5,000 feet below, chequered with crops. Beyond that we could see a little bit of the Delei river and follow its valley through the mountains to the Lohit, and make out patches of cultivation and clearings across the Lohit. Sadiya itself was considerably less than a hundred miles away, and in the south-west, where the slope of the mountains flattened out, we could see the edge of the plain. Far away to the south, beyond the Lohit, the mountains of the Assam-Burma frontier rose faintly against the opalescent sky.

We were only a decent day's march from Chibaon, and once there we felt we would be in a more friendly and familiar country. Above Chibaon the valley changes its character; the path leaves the river and climbs up and down over high spurs, the scenery is harsher, the flora changes from tropical and sub-tropical to temperate and alpine, and the people, who cultivate Wheat and Barley, as well as Maize, are more hostile to strangers. But from this look-out ridge we could see none of the country to the north, which was hidden by the forest on the north slope; only southwards, over the tops of the stunted trees, could we see the softer curves of the mountains, cleft by invisible, winding rivers. Away up the ridge, past the temperate forest, past the fringe of Fir trees, and the Rhododendron tangle, Polon bulged up bare and menacing, hiding all but the twin summits of Kaso, which is the first high peak on the Delei-Dou divide. Below Polon, that is, towards the Lohit valley, comes Atsin, a comparatively low hummock, about 12,000 feet high, on the divide above Chibaon; and after that, nothing—the ridge simply falls away to the Lohit in steep arcs. From our Kaso ridge on the other hand, a few miles to the north, we overlooked the sterner half of the valley. To the south, owing to the bend of the Delei, the overlapping spurs cut out the Lohit altogether; northwards, the horseshoe of sharp peaks, snow-clad for most of the year, which surround the head of the Delei valley, were always in view—when it was not raining or snowing.

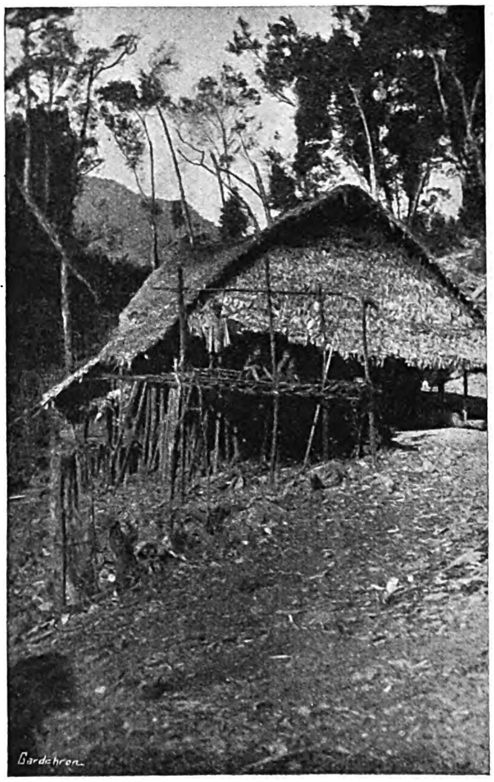

FIG. 152.—A NATIVE HUT IN THE HILL COUNTRY.

The change of the monsoon is usually ushered in by thunderstorms, a sudden fall of temperature, a change in the direction of the wind, and by the dissipation of the rain mist, such clouds as still prevail having firm outlines. Some at least of these conditions had been fulfilled, and we felt certain that we were going into reverse; in four or five days now I expected to start for Kaso, although the longer it could be delayed with safety, the better. I remembered that in the Seinghku valley in 1926, after the first week of October, the weather had been glorious, except for an occasional storm; nor do they expect much rain in Sadiya after September.

Meanwhile, a number of Mishmis had come up and gone off with all our spare gear to Chibaon, where it was dumped, to await our arrival *en route* for Sadiya at the end of the month. We ourselves could not go direct to Chibaon, but would have to return to Meiliang first, where most of our kit was stored; and then down the valley to Chibaon and the Lohit. That night (October 4) after dinner, the moon being at the full, and the owls screeching above our camp, Buttercup and I once more walked up to the look-out. It was a fine scene, with the ebony shadows of the mountains flung obliquely across the moonlit valley, and a few stars glowing warmly in a metallic-looking sky; but I noticed with misgiving that sometimes a coloured halo surrounded the moon, and that it was caused by streamers of thin mist which, from time to time, came flying up from the direction of the Lohit across the moon's disc. However, it was impossible to believe that such a superb night could be followed by anything but a cloudless day. It was ten o'clock when we returned to camp—the owls were still noisy—and in view of the approaching alpine tour, before turning in I made hasty preparations to climb Polon again on the following day.

Before dawn on October 5 the rain was crashing down once more, and although I breakfasted by candle light in the ghostly dawn, the weather was so utterly bad that I decided to postpone the climb. Not since June had we had such a deluge: it was the beginning of a nine days' storm which ruined all my plans.

At this season a new crop of plants was flowering in the middle forest. Among notable species were an Arisaema with a green spathe drawn out at the tip into a fishing line, a handsomely mottled stem, and a shining leaf composed of six or eight wedge-shaped spokes. It grew scattered in the forest, and was nowhere common; as usual, for every female plant there were three or four males, and since it was not possible to get seeds of this species, I dug up some rhizomes to send home. Secondly, a climbing Fumitory (Dicentra ?) with smooth, pale, sea-green leaves and clusters of bright yellow flowers, turning orange with age, and followed by little, dangling, red Pear-drops. This was a rampant annual, above ground, dying down to the base in winter. I have met with it previously in Burma, but low down, at about 4,000 feet altitude, with paler flowers; this form from 8,000 to 9,000 feet, if it is the same species, is a distinct improvement on the lowland form, and might be quite hardy. Anyhow, it is well worth growing in a cool house, as the foliage is distinct, and flowers and fruits are seen at the same time. There were also several species of Crawfurdia, growing in tense spirals, punctuated with dangling bells, up the Bamboos. One species had pale flowers, white with violet bands, or violet with white stripes; that was not of much account. Another had dark, glossy, violet flowers, and was more handsome—I have not seen it before. In a previous chapter I referred to these twining Gentians as worth a place in the cold house—the purple C. campanulacea which I saw in the Naga hills was specifically mentioned. This violet-flowered plant is even better, but there was no chance of getting any seeds. The Magnolia* was now in good bud, and I expected it to flower almost any day; but it had not flowered by October 26, at any rate! In the middle of the month a Schima bloomed freely, but the flowers are small. Lastly, several Orchids, including a Cirrhopetalum, flowered in October.

Although the deluge of October 5 was distressing, I did not take it very seriously. Of course, it is quite impossible to state just when the monsoon will end, but even if the weather was unsettled for the next fortnight, it need not necessarily upset my plans, although I should have preferred fine, settled weather. But when, day after day, it continued to pour with rain, and not only that, but to blow furiously from the north, our faces grew longer and longer. "The north wind doth blow, and we shall have snow," I thought to myself, as I sat in my tent with numbed feet. It was bitterly cold, a damp, penetrating cold, and the mountains were entirely hidden by a thick blanket of mist. Never had our camp been such a bog as it was now; a small river flowed through Buttercup's tent, a lake formed in mine. We could not light the stove because the oil was finished. Worse still, by October 5, the Rice, too, was finished, and Luso had to subsist on maggoty flour, although Buttercup, by strategy, induced him to take some tinned milk, of which, thanks to self-denial, earlier in the year, we now had a small surplus. By the evening of the 8th the wind had shifted again, and was blowing boisterously from the north. It was a sad day; during a lull, I went up to the look-out, and behold, the entire ring of mountains, from Kaso onwards, was white with snow! But what else could we expect! Then the clouds blotted out the painful scene once more.

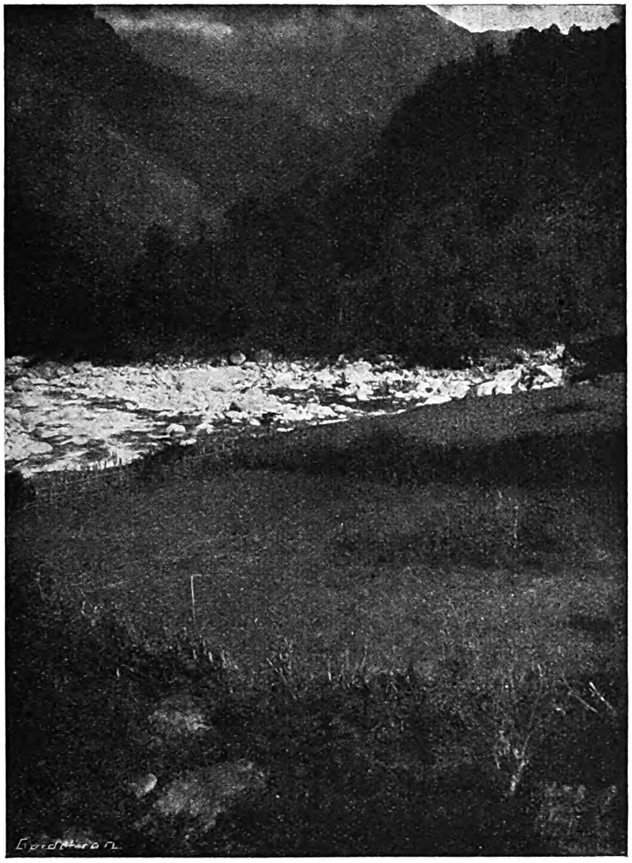

FIG. 153.—THE DELEI VALLEY.

On the 9th, Buttercup and I could stand it no longer, so up the mountain we went, and for eight hours we buffetted with the wind, soaked to the skin, while we collected Rhododendron seeds. I ascended to 11,000 feet, and cold as it was, it was better than sitting in a tent, storm-bound. We collected seeds of about seventeen Rhododendrons, as well as a few other shrubs. The storm continued with unabated fury, the wind blowing alternately from the south and from the north; on the night of the 10th, it blew a gale, and the rain was the heaviest we had experienced in the Delei valley. We were not surprised, therefore, when, during an armistice on the 11th, we noticed that Polon was now snow-clad. The chances of reaching Kaso from the Polon ridge were now remote. In my diary is the following comment under date October 11. "The Delei valley has rebuffed us and flouted us in every possible way; but it has kept its most deadly weapon for the last round." And then, under date October 12-13. "No change in the weather . . . Violent storm from the north on the night of the 12th, and a perfect deluge of icy-cold rain on the morning of the 13th . . . I am continually thinking of the plants now lying under the snow, and of how to save something . . . the problem of Luso's food is acute . . . on the afternoon of the 13th, it began to clear up . . . Polon has a good cap of snow, Kaso is white, all along the ridge as far as Saluenense Hill, and even Atsin has a little snow lying on it. The river is enormously swollen."

However, the 14th was fine at last, although by midday there was a lot of cloud about. I went up the mountain and collected certain seeds; and when I got back to camp I found that all the Mishmi coolies had arrived. Thereupon, we arranged that next day Buttercup, whose foot was too sore to allow him to do a big climb, should return to Meiliang with the kit, while Hubble, the Meiliang Gam and I went up to the cave and collected on Polon. If we could get along the ridge to Kaso we would do so, but so much snow had fallen, that it seemed improbable. If we could not get on, we would do two days' collecting on Polon, return to Meiliang in a day, and then go up the valley and tackle the Kaso ridge from our old camp. After getting everything fixed up we went to bed.

F. Kingdon Ward.

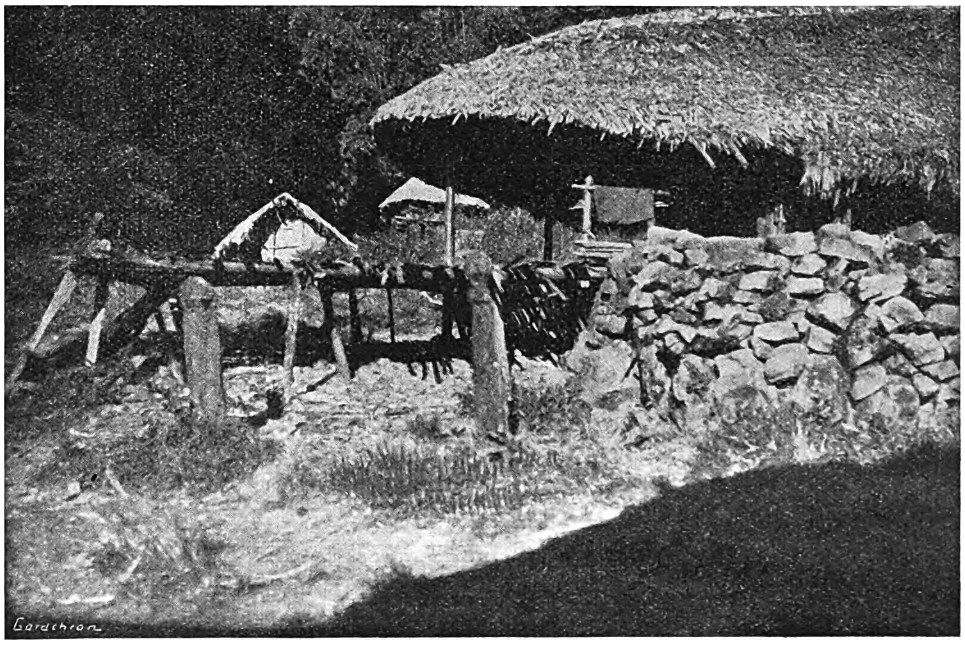

FIG. 154.—A CHULIKATA MISHMI HUT.

AN ENGLISH GARDENER IN CHILI.

(*Continued from p.* 306.)

UNDER the third group there are a few plants well-known in cultivation, especially Drimys Winteri and Gunnera chilensis, the former being of botanical interest and prized as an uncommon tree in the more temperate parts of England, while the latter is well-known as a splendid specimen plant for waterside planting. In Chili its long leaf petioles are regarded as a delicacy known locally as Pangae and eaten raw. In the central provinces these species are generally found in valley bottoms where there is always water, either actual springs or running streams. These Quebradas, as they are called, are in most cases deep but comparatively narrow, and they are invariably clothed with dense vegetation, in marked contrast with the plateaux above.

Another plant worthy of note which grows side by side with these is Fuchsia macrostemma —El Chilco—which has long, slender stems, and trails among the branches of other shrubs and bushes, relying, to a great extent, upon them for support, and frequently reaching a length of ten feet to twelve feet. The solitary flowers are borne on long, slender peduncles, giving the plant a very graceful appearance, while the distinct colours of the flowers—red calyx and violet corolla—always attract attention. The flowers are specially attractive to a small species of humming bird, locally known as Picaflor, which, with wings moving so rapidly as to be invisible, remains stationary in the air, while thrusting its long beak into flower after flower in search of nectar; this bird is stated to be the most effective agent of pollenation.

A plant of similar habit and frequently intertwined with the Fuchsia, is Eugenia Chequen, called, together with Myrtus apiculata —El Arrayan. This has small, glossy green leaves that show off to good effect the numerous white flowers which closely resemble those of the common Myrtle. Another interesting example of this habit of growth is a species of Azara with umbels of bright yellow flowers, which appear to consist of stamens. The plant has the peculiarity of possessing two sets of leaves; large ones approximately three inches long by one-and-a-half inch broad, and small leaves not an inch long and about three-quarters-of-an-inch wide, in fact, almost circular; as both types arise from the same node, and as they lie in the same plane, it may be regarded as an excellent example of leaf mosaic.

The most common undergrowth in these valleys is the rather coarse-growing Fern, Blechnum chilense; it has erect, pinnate fronds, four feet to six feet high; frequently the stem reaches a foot or two high, then flops down in the swamp, turns upwards, and again commences to grow. Two species of Adiantum and Aspidium rivulorum are also fairly common, and an Equisetum with a very fine habit of growth is also plentiful; the last is, I believe, E. bogotense, and is used as medicine when infused in water; it is also extensively and effectively employed for cleaning brasswork.

Farther south, where the valleys are generally wider and where there is much more water, a wider range of Ferns occurs, including Tree Ferns, such as Lophosorus glauca (Alsophila pruinata, Gay), which grows so much as ten feet high and covers an area of so much as fifteen feet. Blechnum magellanicum also has large pinnate fronds up to six feet long. Here, also, is the home of Lapageria rosea, the national flower of Chili, known as El Cophui, while the fruits, which somewhat resemble a small Pear, are known as Pepinos, and eaten. For most of the year it is necessary to wade through swamps to reach the plants, and the youngsters of this part of the country find it a profitable source of revenue to gather bunches of flowers and besiege passing trains at all wayside stations; a huge bouquet can be purchased for 1s.

To return to the central provinces. I have dealt up to the present only with those plants and trees which grow either actually in or beside water, that is in the valley bottoms. The slopes of these valleys present something of a transition from water-loving to drought-resisting species. Naturally, the flora also varies with the soil, and to a considerable extent with the direction; those which run north to south are frequently comparatively bleak, probably owing to the cold winds from the Antarctic, while others in the same locality, but with a more favourable aspect, are clothed with vegetation. One sometimes finds valleys which are clothed with trees and abundant vegetation on one side, while the opposite side carries an extremely xerophytic type of vegetation.

It is difficult to decide what are the factors responsible for this phenomenon; is it due to aspect, soil conditions, drought, or to a combination of these or other factors? It is chiefly on these more arid slopes that Puya (Pitcairnia) coerulea grows in profusion. This species is not so stiff and erect in habit as P. chilensis; the leaves are grey and more arching, while the thick stems are more prostrate and consequently the rosettes are wider apart. The inflorescence, generally about eight feet or nine feet high, is also lighter in appearance, and the floral colour is more striking—a cold, greenish-blue.

The columnar Cereuses (C. Quisco or C. chilensis) make huge specimens up to ten feet or fifteen feet high, with, frequently, ten or twelve parallel stems. Here also grows a spherical Echinocactus with salmon flowers that are followed by red fruits; it grows about eight to ten inches in diameter and has thick, strong spines. In the more luxuriant areas is found the Macqui, Aristotelia Macqui an evergreen dioecious tree, and quick-growing, provided it has its roots near the water. The shining, bright green, ovate leaves are about two inches long, and borne on bright red branches which, later, turn to a dull violet. The fruits—round, dark purple berries—are much esteemed and are used for confectionery and a native drink; the juice of the fruits stains everything and is employed for colouring wines, etc.

One of the commonest trees on these slopes is the Peumo (Cryptocarya Peumus), which reaches, under favourable conditions, a height of thirty feet. Another not previously noted is El Molle (Schinus latifolius), an evergreen of low, spreading habit, carrying innumerable panicles of small, white flowers followed by shining, black berries.

Among the varied undergrowth, in situations which are bone-dry for several months of the year, Solanum tuberosum is found in abundance; vigorous and healthy to a degree, it bears no indication of disease! The stems trail along in a tangle, among other plants, to a length of five feet or six feet. Writing from memory, the whole plant seemed to be more hairy than the cultivated varieties, and the foliage much larger. The flowers are very similar, almost white, but with violet diffused lightly through the corolla, particularly towards the centre, and contrasting well with the column of orange stamens. When lifting the roots, however, there is disappointment, for the tubers are never larger than a Walnut. Whether they are truly indigenous here is an open question, as it is recorded by the Spaniards that the Indians used them extensively as food prior to the Spanish conquest.

There are two or three lianas which take full advantage of the crowded conditions, especially common being a Composite with inflorescences of a soft, down-like character, brown, tinged with red. Its stems climb through the branches, particularly of the Peumo, like thick ropes, sometimes so much as four inches in diameter, and when they reach light they branch freely, all the smaller branches being furnished with hooked appendages. As there is one hook at each node, and pointing down, the plant is effectively anchored to the branches of the host tree. The leaves on the young growths are two inches long by two inches broad, cordate and serrate, the teeth being armed with short spines; in the older growths the leaves are narrower and more elliptic. A species of Vitis or Cissus is also very vigorous, clinging to the trunks of the trees until clear of the branches and then overhanging; I am not sure whether this is indigenous or introduced and gone wild.
G. W. Robinson,

(*To be concluded*).

THE ROMANCE OF OLD APPLE TREES.

In many of the grass orchards attached to farmsteads and manor houses in the West Country there are old Apple trees which are historical, and about them is an atmosphere of sentiment and romance. In a number of the orchards I am describing, overcrowded, may be, and devoid of any law and order in the scheme of planting, there are to be found Blenheim Pippin trees, and their presence can be traced back to a period when the only object in planting orchards was to produce Apples to grind into cider, then the staple, if not only, beverage, consumed by the farmer, his family and his work-people.

The cider Apples are generally a mixed lot, some bearing local names and others nameless, and raised in the first place from the pips which were thrown out with the "must" from the cider mill. But while the farmer troubled little about the fruit he grew for cider-making he wanted a few Apples to eat, and even if there were other varieties then available the chief favourite must have been Blenheim Pippin, judging from the number of old trees there are still growing in west of England orchards.

In surveying the gnarled stem and thick limbs of one of these antique specimens one longs to know its history, how long it has been there, the storms it has weathered, the number of owners it has had, and how many tons of fruits it has produced. The chances are that the tree has never been sprayed, the pruning it has had has been restricted to occasionally cutting out a few dead branches, and the bunches of parasitic Mistleto which may grow on the limbs and never seem to have done any harm. Not only do these old trees bear crops, and will continue to bear for years to come if they are spared by the wind, but they produce Apples of a rich rosy colour and of a flavour the best which a "Blenheim" can give—which is saying a good deal. I may add, in passing, that I took particular note of the Blenheim Pippin classes at the recent autumn fruit show organised by the Royal Horticultural Society, but I saw nothing there that would equal in colour, quality and flavour Apples grown this season on dozens of old orchard trees in the west, because, for some reason or other, it is only from old trees that one seems to get "Blenheims," as a dessert Apple, at their best in point of flavour.

As an instance of the sentiment that attaches to some of the old trees, a farmer I know had a favourite Blenheim Pippin blown down a few years ago, and another person would have cut it up for firewood; but sentiment proved too strong. The farmer had climbed into its branches as a boy to pick the Apples. So had his father before him, and by dint of pulley blocks and considerable labour, the tree was raised into a leaning position, was propped to keep it there, has borne several good crops of fruit since, and seems none the worse for the drastic root pruning it received.

Still, the fact remains that few people can be induced in these days to plant trees of Blenheim Pippin in their orchards, the complaint being that the variety is so long coming into bearing, which is true under present methods of propagation, and there are no records to show how long the old trees stood in the orchards before crops were gathered from them. One thing I do know, however, that once they began to bear they have never failed since, except in their "off" seasons, and there is something very much in favour of planting a variety which has such a record of longevity and productiveness.

In a number of the orchards within a few miles of the city of Gloucester there are old trees of a dessert Apple which was conspicuous by its absence at the R.H.S. Fruit Show. I refer to Ashmead's Kernel, which is distinct on account of its russety appearance and the characteristic mark around the fruit. The presence of Ashmead's Kernel in local orchards may be easily explained because, according to Dr. Hogg's *Fruit Manual*, the Apple was raised more than a century-and-a-half ago by Dr. Ashmead, an eminent Gloucester physician, on a spot which is now one of the busiest streets in the city, and it, doubtless, having earned a local reputation for its dessert qualities, grafts from the parent tree were acquired by interested people, and from these the old specimens in the orchards I have referred to were established There is a romance about them; they have a historical association, and sentiment protects them, but when they go the variety will be lost to the district, for no one plants an Ashmead's Kernel tree now, as it does not come up to present day commercial requirements, and if fruits of the variety are sent into the market they make little money because few people know them, and their appearance does not recommend them; therefore the growers generally reserve these Apples for private customers who know what an Ashmead's Kernel is like when at its best.

An interesting old Apple in Gloucestershire orchards is one called Underleaf, a good cooker and keeper, but the variety—I do not know its origin—has a habit of growing old and then making itself young again. The explanation of this is than an Underleaf after living for the greater part of a century and bearing tons of fruits, will appear to have finished its career, when young wood will break out from the old stems and make a new head, which will go on bearing for many years longer. There is a local saying that you have never done with an Underleaf, and in support of this I know trees in orchards with only the shell of the old stem remaining (hollow in the centre), but yet from this shell young branches have pushed out and the old relics present from a distance all the appearance of young trees.

The trees about which I have written are all old, many others of similar character might be referred to, and I attribute their longevity, vigour and freedom from disease to the method of propagation that was in vogue before nurseries were established and the "raise trees quickly" process of to-day came into operation. If the stems of old orchard trees are examined it will be observed that a few feet above the ground there is a bulge in the thick trunk. This marks the point where the Apple was grafted on to the wild Crab stock, which was planted in the orchards and established as a young tree before it was subjected to the process which Shakespeare describes as "an art which doth mend nature, change it rather, for the art itself is Nature." Names are mentioned still of men who had local reputations as raisers of true Crab stocks, and I have in my possession a section of an Apple tree trunk which I rescued when it was being cut up for firewood. In the centre there is the top of the original Crab stock in which two grafts were inserted One developed into a tree which must have grown for more than a century, bore tons of Apples, died through sheer old age, and when it was being cut up to serve its last purpose the other scion—which had died—was found in the stock, just where the grafter had fixed it.

I venture, in conclusion, to state that, slow although it was, this old world method of propagating orchard standard Apple trees has never been improved upon, and there is an air of romance about the method as well as about the old trees and many of the varieties that are still growing to-day in west country orchards. *G. H. H.*

NOTICES OF BOOKS.

Dessert Fruits.

Like Rolla, Mr. E. A. Bunyard, whose book *The Anatomy of Dessert*[*] I have just read with pleasure and with profit, was born too late into a world too old. Canning, chemicals and cold storage have combined with mass-production and marketing boards to produce a uniformly low standard of food, or, in Mr. Bunyard's words, "the Jonathan Apple and Jamaican Banana level." Gone, never to return, are the days when the seventy-odd "mansions" in Prince's Gate housed fifty French chefs; the Café Anglais, Ledoyen, Foyot, where the fine flower of young England learnt to know the subtleties of the *haute cuisine française* are but the pale wraiths of their former triumphs.

To a country that has lost *joie de vivre*, to a people that count petrol more precious than Pears and would rather have arterial roads than Apple trees, our author unfolds his earthly paradise. Were he commissioned to plant a new garden of Eden, and confined to a single tree or plant of each sort of fruit, this would be his list.

Of Apples, "to the Nordic nations the King," he would plant "Orléans Reinette"; "in the rich golden flesh there is a hint of the Ribston flavour, much of the Blenheim nuttiness, and an admirable balance of acidity and sweetness which combine, in my opinion, to make it the best Apple grown in western Europe."

Of Cherries, "Royal Duke . . . coming about mid-July, perhaps marks the highest. It is a dark fruit, but the richness of its flesh and delicate balance of acid and sugar put it very near the first place of all Cherries in my heart."

In Figs he hesitates between Bourjassotte Grise and White Ischia, so I must settle for him and choose the latter.

Gooseberries: "Glenton Green . . . Did I in a weak moment venture to select one fruit as the best flavoured of all, I rather fancy it would be this on which the lot would fall."

Grapes: "Chasselas de Fontainebleau . . . when well ripened, I place it far before any of our Muscats, be they ever so far loaded with medals. The flesh is firm, yet far short of toughness, sweet, short of sickliness, and the musky flavour not overdone. Every cool vinery should possess at least one of this superb fruit."

Melon: "Blenheim Orange is, I think, still unsurpassed."

Nectarines, Elruge, and Peaches, Peregrine.

Of Pears: "To the Latin nations the Queen of Fruits," Doyenné du Comice, indeed, deserves the regal title, and in spite of the enchanting account Mr. Bunyard gives of the discovery of this fruit *molto bene profumata, squisitissima* on the banks of the Loire in 1849, I maintain that Doyenné du Comice was the particular Pyrus whose

> "immortal taste"
> "Brought death into the world and all
> our woe."

"Ave Imperator!" is our author's greeting to Reine Claude Diaphane, "the King of Gages."

Lastly, comes the Alpine Strawberry, "one of the best of all fruits."

It must not, however, be thought from the symposium I have collected, that Mr. Bunyard is, any more than Samuel Butler, *homo unius libri*. Of all great dessert fruits he goes carefully through the gamut of varieties, noting their flavour, their perfume, the quality of the flesh, and their seasonal apogee. And lest these should become a mere catalogue, the pages are adorned with pretty wit and pleasant anecdote. What can be better than his account of the birth of Cox's Orange Pippin . . . "To Mr. Cox, a retired brewer, we owe this 'good creature,' as Mr. Saintsbury would call it, and we can picture the scene at Colnbrook Lawn, Slough, in 1825. Mrs. Cox would have drawn up her chair by the fire, the evenings are turning a little chilly, while Mr. Cox, who dines at four, is lingering over his port and dessert. 'Ah, my dear, now this is what I call a good Apple. Yes, yes, very good.' 'Pray, is it one of your old seedlings?' says Mrs. Cox, always a little doubtful of home productions. 'On the contrary, it is one of my new ones.' 'Ah well, I don't see how it can be better than a Ribston.' The firelight plays on the cut-glass decanter, and a slight reflection answers on Mr. Cox's nose, as he smiles his wise old man's smile and thinks how women are all alike—and so a great moment in history slips by. But perhaps Mr. Cox was a bachelor . . . "

Mr. Bunyard also suggests appropriate wines to accompany different fruits; here I find myself often in disagreement. He is too fond of a "rich Sauterne," an Yquem. Yquem to me is a sacrament, I drink it only at Christie's auction rooms, with a little bit of cheese, when some good fellow's cellar is put up for sale and he stands me lunch for the last time; wine before or after fruit, but rarely with fruit! I agree that Alpine Strawberries are delicious from a wine glass, but that glass should contain a Mersault or a Sarthe wine rather than a "light claret or Beaujolais."

This book is published in a limited edition, but I feel, indeed, I hope, there are more than a thousand *Feinschmeckers* in our island, and that a new edition will soon be called for. Especially the book is commended to fruiterers, and there is certainly one retail fruiterer, the proprietor of the best fruit shop in London, who may be relied upon to make good use of it.

Finally, Mr. E. A. Bunyard, as a member of the Council of the Royal Horticultural Society, and as Chairman of their Fruit and Vegetable Committee, has a unique opportunity to practise what he preaches; in the restaurant of the R.H.S. there is virgin soil to be tilled, and it is surely not too much to hope that at the fortnightly meetings we shall find in that restaurant not Jonathan Apples and Jamaican Bananas, but rather the best Nordic fruits in prime condition! *William Lawrence.*

Guide to the Flora of the Cape Peninsula.[*]

This is a useful work, and its title is a fair guide to its content. An immense field of labour has been condensed into a series of keys applicable to the various Main Divisions, Families and Genera, and is accompanied by notes as to the locality and flowering period of the various sorts now believed to inhabit the restricted area of the Cape Peninsula, and giving the number of species representing the various genera therein. But the need for a hand-book of this sort is only fully appraised by those whose labours in identification of specimens has been unduly prolonged by the absence of a book of keys.

Every individual differs from every other in at least some respects, and species are but groups of individuals bound together by some genetic bonds limiting variation. The object of a key-guide is, therefore, to bring the apparent chaos presented by nature within the ordered ranks of scientific nomenclature, and to attain this end with the least display of violence. But one should not expect any such system to work infallibly, for the earliest logicians admitted "topics of discussion" which were in their nature "not amenable to classification," and the student will surely find specimens which, after most careful classification, will still seem to be restrained with difficulty in their ordained positions.

We welcome every fresh effort to supply hand-books of this kind suitable for various geographical areas, for there is still a great field of work which has not been touched. Beyond this, there is another field of work of a more technical nature, which, when brought under control, would enable us to determine specimens of certain classes of plants and of bulbs, within a reasonable time. The present system only becomes determinative when flowers and fruits have been secured. But in the case of many Cactaceae many years may pass before a single flower may be obtainable, and so the whole process of identification passes beyond the life-span of the botanist. To avoid this difficulty the late Karl Schumann perfected a key-scheme largely based on the fact that the Cactaceae possess permanent stems always available for examination. To use a key of this kind certainly implies a well-practised observer, nevertheless, his key has been used even to the correct determination of species, the flowers of which the observer had never at any time seen. As this has proved possible in the case of the Cactaceae, will not some one oblige us by producing a key to those South African Amaryllidae whose long-delayed and erratic periods of flowering have been the despair of many botanists. Apart from the leaves which appear every year, the bulbs, tunics and roots have a tale of their own to tell, if any one would systematically examine them.

The author was probably wise when, for the purpose of comparison with alleged Natural Orders, she preferred Engler's system to that of Bentham and Hooker, and her avoidance of needless technical terms is admirable, bearing in mind that the bulk of those using this book will not be professional botanists.

To some it will appear strange to see deciduous Amaryllids described as "Plant with bulb." The "bulb" is, after all, the only permanent part of the organic whole, and should not be named as though it were a mere appanage to a "plant." In fact, modern horticultural use distinguishes between "plants" and "bulbs."

Brunsvigia is described as carrying a "many-seeded" fruit, and Amaryllis as carrying "a few seeds." This requires revision as regards the genus Brunsvigia, which cannot be separated, in a genetic sense, from Amaryllis. Students should give attention to the restricted area dealt with in this work, as many writers have, in a casual way, given "The Cape" as the habitat of many forms of vegetation which cannot be found within many hundred miles of the area dealt with in this *Guide*.

By acquaintance with specimens gained *pari passu* with theoretical knowledge, the student may advance quickly in his studies, and this book will show him how to do it without waste of time. He will find the figures more than helpful, as some of them are portraits of merit. *A. W.*

THE GENUS PRIMULA.

(*Continued from p.* 304.)

Secundiflora (Franch.). Secund-flowered P. (Sikkimensis).

A beautiful, deciduous, perennial species with a tuft of a few Papyrus-like, sub-erect, oval, oval-oblong or lance-shaped leaves from two to five inches long, tapering to a winged stalk; margins recurved, minutely toothed; upper surface more or less smooth, underside coated with yellow meal in the young leaves. Flower stem six to fourteen inches tall, bearing one to three superposed, one-sided umbels of six to twelve nodding, fragrant, deep crimson blossoms, faintly tinged with purple, on slender, graceful stalks, one-half- to three-quarters-of-an-inch long. Corolla concave or funnel-shaped, half- to three-quarters-of-an-inch across, with broadly egg-shaped, scarcely notched lobes; tube about half-an-inch long, cylindrical below, funnel-shaped upwards, slightly larger than the calyx. Flowers in June and July. Introduced in 1908. *Gard. Chron.*, 1914, Vol. LV, p. 357, Fig. 158.

---

[*] *The Anatomy of Dessert*, by Edward A. Bunyard. London: Dulau and Company, Ltd., 1929. Price 10s. 6d. net. First edition limited to one thousand copies signed by the author.

[*] *Guide to the Flora of the Cape Peninsula*, by M. R. Levyns, Lecturer in Botany, University of Cape Town; with 199 illustrations. Juta and Co., Cape Town. Price 15s. 6d. net.

Grows in damp alpine pastures and on the margins of glaciers in the Lichiang range, in north-western Yunnan, western China, at 12,000 to 15,000 feet above sea-level.

Culture: Grow it in good loam and peat and treat as a bog plant when in growth.

SEPTEMLOBA (Franch.). Seven-lobed P.
(Cortusoides-Geranioides).

An elegant, deciduous, perennial species, with a sparsely-leaved tuft of rounded leaves from two to three inches across, heart-shaped at the base, borne horizontally on slender, hairy stalks from two to six inches long; margins divided into seven blunt, toothed lobes; both surfaces clothed with glistening hairs. Flower stems seven to twenty-four inches tall, very slender, hairy, bearing one, or at times two one-sided umbels of two to six semi-pendulous, fragrant, reddish-purple blossoms on short, curved stalks. Corolla nearly funnel-shaped, three-eighths- to half-of-an-inch across, with egg-shaped, slightly notched lobes; tube funnel-shaped, about three-eighths-of-an-inch long, exceeding the calyx in length. Flowers in August. Introduced in 1908. *Gard. Chron.*, 1915, Vol. LVIII, p. 297, Fig. 105.

Grows in damp, shady spots in and on the margins of woodlands, on the mountains of Yunnan and Szechuan, in western China, at 9,000 to 11,000 feet above sea-level.

Culture: Grow it in good loam and Oak or Beech leaf-soil, in a cool, shady spot.

SERRATIFOLIA (Franch.). Saw-leaved P.
(Candelabra).

A very beautiful, deciduous, perennial species with a short, thick rootstock and rosettes of thin, smooth, non-mealy leaves with oblong, oval-oblong or egg-shaped blades gradually tapering to a long, winged stalk, in all four to eight inches long; margins edged with sharp, often irregular teeth. Flower stems nine to twenty-four inches tall, bearing one or several, superposed umbels of about six yellow blossoms, with a broad bar of deep orange-yellow down the centre of each petal from tip to base. Corolla concave, about one inch across, with egg-shaped, not very deeply notched lobes; tube cylindrical below, dilated in the throat, about half-an-inch longer than the calyx. Flowers in June and July. Introduced in 1908.

Grows in damp alpine meadows on limestone formations, in Yunnan and north-eastern Upper Burma, at 10,000 to 12,000 feet above sea-level.

Var. roseo-tincta (Forrest) has fragrant flowers similar to the type in colour, but flushed with purplish-rose; plant nine to eighteen inches tall. Flowers in July; north-eastern Upper Burma, at 11,000 to 12,000 feet.

Var. unicolor (Forrest) has fragrant, pure pale yellow blossoms; plant nine to sixteen inches tall. Flowers in June; north-eastern Upper Burma at about 12,000 feet. *Gard. Chron.*, February 18, 1928, p. 121, Fig. 65.

Culture: As for P. Poissonii, with the addition of lime in some form to the compost.

SERTULUM (Franch.). Garland P.
(Farinosae).

A little-known species with a rosette of membranous, oblong or egg-shaped, blunt leaves, tapering to a long, winged stalk; margins furnished with sharp teeth; both surfaces more or less smooth. Flower stem about twice as long as the foliage, bearing a many-flowered umbel of purple, violet or white blossoms on stalks two or three times longer than the calyx. Corolla concave, five-eighths- to three-quarters-of-an-inch across, with oval, bifid lobes; tube longer than the calyx.

Grows in damp situations near Tchenkeutin, in Szechuan, central China, at about 8,000 feet above sea-level.

Culture: As for P. farinosa.

SESSILIS (Royle). Stemless P.
(Petiolaris-Sonchifolia).

A deciduous, perennial species with a somewhat stout, scaly rootstock crowned with a rosette of broadly lance-shaped, oblong, or egg-shaped-lance-shaped, rather thin leaves, rounded at the tip, tapering to a short, winged stalk, in all one inch to two inches long; margins sharply toothed as though gnawed by insects; both surfaces smooth. Flower stem obsolete, flowers numerous, borne on slender, more or less smooth stalks one inch to two-and-a-half inches long. Corolla about one inch across, with egg-shaped, oblong-oval or heart-shaped lobes, margined with sinuate teeth; tube about five-eighths-of-an-inch long. The colour of the blossoms of this species has not been recorded. Not in cultivation.

Grows in damp, mountain woodland pastures in the north-western Himalayas, at 9,000 to 12,000 feet above sea-level.

Culture: Good loam and leaf-soil in a cool, half-shady spot, should suit it.

SIAMENSIS (Craib.). Siamese P.
(Soldanelloidae).

A pretty, perennial species with a tuft or rosette of oblanceolate or oblong-oblanceolate, membranous leaves about three inches long and one inch wide, rounded or blunt at the tip, tapering at the base into a stalk about one-and-a-half inch long; margins furnished with a few obscure teeth and densely fringed with fine hairs; upper surface thinly covered with soft hairs, underside densely hairy on the nerves. Flower stem solitary, coated with white meal among the blossoms, and bearing a few violet blossoms in a head or short spike. Corolla about five-eighths-of-an-inch long, with broad, deeply divided lobes, margined with irregular teeth at the tip; tube funnel-shaped, about half-an-inch long. In cultivation in 1923.

Grows in open situations in clefts of limestone rocks at Doi Chieng Das, in Siam, at 5,000 to 6,000 feet above sea-level.

Culture: As for P. Reidii, but probably too tender to be tried out-of-doors in this country.

SIBIRICA (Jacq.). Siberian P.
(Farinosae).

A charming, deciduous, perennial species with crowded rosettes of pale green, membranous, smooth, non-mealy leaves half-an-inch to one inch long, with elliptic-oval or oval, blunt blades contracted into short stalks; margins entire or obscurely toothed. Flower stem three to seven inches tall, bearing a loose, many-flowered umbel of lilac or rose-coloured blossoms, on slender stalks half-an-inch to one inch long. Corolla three-eighths- to three-quarters-of-an-inch across, divided into five broadly heart-shaped, deeply-notched lobes; tube cylindrical, frequently twice as long as the calyx. Flowers in July.

Grows in damp places usually in exposed situations among very dwarf herbage, in the Altai, Kunlun and Baikal Mountains of central Asia and Siberia, also on the mountains of western Tibet, Kansu and Daurin, reaching an elevation of 16,000 feet above sea-level. Introduced in 1818. *Gard. Chron.*, 1916, Vol. LIX, p. 45, Fig. 20.

Var. arctica (Pax). Calyx about half the length of that of the type, corolla tube twice as long as the calyx. Arctic Europe and Asia.

Var. brevicalyx (Trauv.). Tube of corolla nearly twice the length of that of the type; inhabits the same localities as the type.

Var. integrifolia (Pax). Tube of corolla but little shorter than the calyx. Arctic Europe, America and Asia.

Culture: As for P. farinosa.

SIEBOLDII (E. Morren). Siebold's P.
(Cortusoides).

A beautiful but variable deciduous, perennial species with a tuft of oval or oblong leaves, two to four inches long and one-and-a-half inch to two-and-a-half inches wide, heart-shaped at the base, borne on hairy stalks about equalling the blade in length; margins cut into numerous unequally toothed lobes; both surfaces densely clothed with fine hairs. Flower stem four to eight inches tall, hairy, bearing an umbel of many blossoms varying from rose to purple and white. Corolla from three-quarters- to one-and-a-half inch across, with heart-shaped or egg-shaped, deeply notched and lacerated, or nearly entire, rounded lobes; tube slightly longer than the calyx. Illust. in *Journ. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Introduced in 1861.

Grows in moist meadows in the Province of Kiusiu, Nippon, Japan.

Culture: Light, rich loam, in a moist, open situation, not too much exposed to the sun, with protection from severe frost and damp in winter, are the conditions indicated.

SIKKIMENSIS (Hook. f.). Sikkim P.
(Sikkimensis).

This elegant, deciduous, perennial species produces a tuft of thin, oblong-egg-shaped or oblong-spathulate, blunt leaves, tapering to a broadly-winged stalk, in all from four to eight inches long; margins furnished with sharp, saw-like teeth; both surfaces more or less smooth, non-mealy. Flower stem eight to twenty-four inches tall, fairly stout, at times mealy upwards, bearing an umbel of six to thirty crowded, nodding, faintly fragrant, yellow flowers. Corolla concave, half- to two-thirds-of-an-inch across, with five rounded, notched lobes; tube funnel-shaped, a little longer than the calyx. Introduced in 1850. *Bot. Mag.*, t. 4,597.

Grows in wet places in the eastern Himalayas, reaching an elevation of 15,000 feet above sea-level, also in moist meadows by streams, on the mountains north-east of Atuntze, in north-western Yunnan, at 12,000 to 13,000 feet.

Culture: Grow it in good rich loam and peat and treat as a bog plant when in growth; usually not very long-lived. *A. W. Darnell.*

(*To be continued.*)

HOME CORRESPONDENCE.

The Need of Education for Gardeners.—The time of year has once more come round when the gardener has a little spare time. During the summer he is far too busy in the garden for much reading of any sort, but now, with the end of "Summer Time," and the advent of long, dark, cosy evenings, I would suggest to any gardener who may read these notes that he cannot better employ his time this coming winter than by an intelligent study of his subject. Gardening, undertaken intelligently, calls for much study, as apart from the actual theory and practice of gardening (in itself a fairly extensive subject) there are many closely allied subjects that should be mastered. In these days of great competition, when it is only the most capable who can command the best paid work, it does seem very essential that gardeners, just as much as other people, should do their utmost to make themselves as efficient as possible; for the better trained and educated they are in their profession, so much the more are they helping to raise that profession to a better position, with better pay for all. There has been a great deal of discussion lately in the daily papers as to whether examinations are, or are not, of any use, but there is this point of view about it, there is nothing that makes one read up his subject so thoroughly as preparing for an examination. A person may make up his mind to set himself a course of study during the winter, but the probability is that unless there is an examination at the end of it, he will not attach overmuch importance to that study, and anything and everything else will come first. Friends will respect your evenings if they know there is a serious matter of an examination ahead, but not otherwise; they will just think you are a "freak" for sticking to your books, when you might go to the pictures. There are many of the younger generation of gardeners who are doing their level best thus to educate themselves, and an increasing number sits every year for the R.H.S. General Examination. The right point of view in gardening is that you have never finished learning, and after the R.H.S. General Examination, then comes the National Diploma in Horticulture—first the Preliminary Section and then the Final, which is quite a stiff examination, demanding much study and concentration. The time is past and gone (except in some of the more remote country districts) when it was considered good enough for a man to do as his father, grandfather, and more distant ancestors, had always done. Possibly the great majority of young men start their gardening life under a good gardener in some big garden, where to have been employed for a few years was thought sufficient to give a gardener a standing for the rest of his life; and so it may be, but it does not give him a knowledge of the theory of his subject. Think of the study of botany, that science "which endeavours to answer every reasonable question about plants," and tells of the structure, work, and physiology of the plants, knowledge of which helps the gardener enormously in the cultivation of plants. Then, the study of insect pests and diseases is most essential, and far too little attended to by many gardeners. Also, some knowledge of the chemistry of soils and manures is of the greatest value to the gardener in his cultivation of the land; new methods are being discovered continually, and to keep his knowledge and practice up-to-date, a man must ever be learning. In fact, in gardening, everyone is really a learner; even the oldest and wisest can never really penetrate to the end of this vast and fascinating subject. *M. G. Kennedy-Bell, Hornsey Lane Gardens, Highgate, N.6.*

Storing Plants during Winter.—There are quite a number of plants that require storage during the winter months, especially those that have bulbs, tubers or rhizomes. Some may require a stove temperature, notably Caladiums, while a number require a much lower temperature. Bulbs and tubers are probably best stored in the receptacles in which they have been grown, but where space is limited they may be turned out and stored in boxes of dry sand. Cannas are best stored under the staging in a cool greenhouse, on an earthen floor, where they may receive a certain amount of moisture. Cannas are often difficult to start into growth in the spring if allowed to dry out too severely. Large specimen plants of Hydrangeas, Agapanthus, Crinums and Fuchsias may be stored in a frost-proof shed, preferably with an earthen floor, so that a certain amount of natural moisture is assured. If the building is not quite frost-proof, cover the plants with rough hay during severe weather, but see that this is removed before growth becomes active in early spring. *T. P.*

R.H.S. Autumn Fruit and Vegetable Show.—When the Council of the R.H.S. decided to alter the classes for collections of vegetables it was a good thing for many who wished to compete, as these classes were arranged for large establishments with any number of men employed, for medium-sized establishments, and also for single-handed gardeners; all this has made competition fair. But could not the Council take such steps at their fruit show? Take the Grape classes; I think I am right in stating that nearly all (if not all) the prizes were won by large establishments; could not the large class for Grapes be confined to the large establishments—the same as in the case of the class for twelve kinds of vegetables—leaving the class for two varieties of Grapes for the medium and smaller establishments. My employer, who is a Fellow of the R.H.S. thought it unfair that the medium-sized establishments were not "protected" from the larger establishments, who have better facilities for growing Grapes. The man in charge of a medium-sized garden can grow Grapes well enough, but he is obviously handicapped. I have one large vinery (which ought to have been partitioned off when it was made), but I cut ripe Grapes in July and late Grapes up to the new year (bunches weighing 3½ lbs.) out of the same house. While at the show, I heard some bitter complaints concerning unfair competition—there should be some grading of exhibitors in regard to their facilities; some said they would not compete again, and that is the decision of my employer, unless the suggested grading is made. *A Sussex Exhibitor.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

(*Concluded from p.* 311.)

IRELAND.

Tyrone.—Pears, Plums and Cherries have been very disappointing this season. After a most abundant display of bloom and apparently a good set, the greater number of fruits fell off when they should have been passing through the first swelling. Pears are very scarce, the only variety bearing any quantity of fruits being Hessle, with about half-a-crop. Plums were little better; a few trees of Victoria were the only ones to carry a moderate crop. Cherries were very scarce, May Duke being the principal variety grown here. Apples are variable, those of the Codlin type, Bramley's Seedling and one or two others carrying fair crops, while Lane's Prince Albert, which rarely fails to bear heavily, is but lightly cropped. All small fruits were good, especally Gooseberries and Black Currants. *Fred. W. Walker, Sion House Gardens, Sion Mills.*

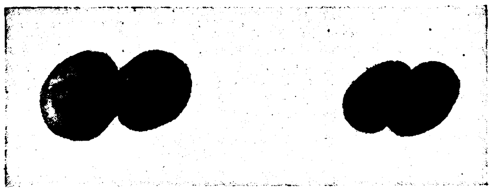

FIG. 155.—UNITED SOYA BEANS.

Down. — The long, continued drought shortened the crop of Raspberries, and Apples, in general, are inclined to be small, otherwise the fruit crops are good. The absence of Gooseberry mildew is the greatest feature to report. *T. W. Bolas, Mount Stewart, Newtownards.*

Cork.—Considering the peculiar climatic conditions experienced during spring and early summer, all fruit crops have turned out better than was expected. Apples are good in the majority of gardens and orchards. Plums and Pears have been good on walls, but irregular in the open. Among bush fruits, Gooseberries were outstanding. Black Currants, Raspberries, and other soft fruits were also good, but as a result of the prolonged drought and dry winds during the ripening period, their crops were of short duration. Apple scab is not so prevalent as in past seasons, but red spider, Plum aphis, American blight and American Gooseberry mildew have been very troublesome in plantations where winter spraying was neglected. *J. Dearnaley, 17, St. Patrick's Terrace, Magazine Road, Cork.*

Kilkenny.—Apples carried a wealth of blossom, but the set was disappointing, except in the case of trees which carried a light crop last year. Last season, a very heavy crop combined with a dry autumn to exhaust the trees. Pears and Plums set very well, and carried good, clean crops. Strawberries, although deficient in leafage, carried good crops; other small fruits also were good, but Apricots did not set so well as is usual here. Insect pests have not been troublesome, and the weather has, on the whole, been favourable, good rains having fallen in contrast to the drought experienced during the first six months in England. *T. E. Tomalin, Bessborough Gardens, Piltown.*

ISLE OF MAN.

Castletown.—Strawberries were very promising in bloom, but dry weather spoilt the setting of the fruits. Cooking Apples, in general, are carrying heavy crops, but dessert sorts are poor. Bush fruits, especially Gooseberries and Black Currants (the latter on stiff, heavy soil) fruited exceptionally well. Cherries set well on standards, but the fruits dropped when stoning, owing to the dry weather experienced at that time. The Gooseberry bushes are free from mildew.—*Frank Large, Great Meadow Gardens, Castletown.*

UNITED SOYA BEANS.

At one of the sessions of the Scientific Committee of the French National Horticultural Society, MM. Vilmorin showed some Soya Beans united in two's (Fig. 155). Two such cases were found, the one a Soya with a black seed, the other with a yellow seed. The phenomenon appears to be exactly on a par with that observed in the curious Peas with united seeds—"Chenille" (caterpillar) Peas—which were studied at Verrières. (See Comptes Rendus de la 4e Conférence de Génétique, Paris, 1911, "Ph. de Vilmorin—étude sur le caractère 'adhérence de grains entre eux' chez le Pois 'chenille'"—and A. Meunissier "Observations sur l'hérédité du caractère 'Pois Chenille.'" (*Genetica*, 1923).

However, while in the case of the Pea this characteristic is hereditary, it does not appear to be so with the Soya; at any rate, two united seeds previously found at Verrières on a Soya with yellow seeds which were sown last year did not reproduce the character. However, it is a curious phenomenon, which helps to bear out the theory of Professor Vavilov, in his "The Law of Homologous Series in Variation" (*Journal of Genetics*, April, 1922), which maintains that the same series of variations always presents itself in allied plants. To our knowledge, this curious anomaly has never been observed in any other Leguminous plants except Peas. It would be interesting to know if it has ever before been known to occur in the Soya. *A. M.*

VEGETABLE GARDEN.

HARICOT BEANS.

When I was admiring Messrs. Sutton and Sons' glorious group of vegetables at the Autumn Show I asked Mr. Leonard Sutton why he did not show baskets of Haricot Beans, and he told me that although they were grown during the war, no one wanted them nowadays. On the same day, in one of the morning papers, I read that the frequenters of smart restaurants were beginning to take hints from the good things served at humbler establishments; among these were baked Butter Beans, now much in demand at places like the Ritz and the Savoy. They certainly are very good, especially with mutton, but the ordinary large white Haricot is a bit filling. On the other hand, the pale green Flageolet has always had its place in the *haute cuisine française*, and is most delicious.

The standard variety is Roi des Verts, and the grains are under half-an-inch long; the Beans must be pulled, tied in bunches, and suspended to ripen in a sunny, airy place; if the pods are allowed to turn brown, the pale green colour of the seed also fades and this, although not materially affecting the flavour, spoils their appearance.

A very fine French Bean is Sutton's Early Giant, which not only is the quickest Bean to mature, but when cooked is notable for quality; it is dark green, tender and full of flavour. It was the first Bean to be picked here last March, and now we have a couple of lights which will last us well into November. Sown in the open, the pods are ready within six weeks of sowing. *William Lawrence, Burford.*

SOCIETIES.

NATIONAL SWEET PEA.

A RECORD ANNUAL MEETING.

During its twenty-nine years of existence, the National Sweet Pea Society has held Annual General Meetings of various characters. There have been the sedate meetings when everything proceeded placidly and according to expectations. There have been occasions when the air has been thunderous, but nothing exciting has happened. There have been stormy meetings which have rivalled some of our noted political gatherings, when the Chairman's task has been no enviable one. But all these were before Mr. Harold Beale became the Society's President. A meeting under his chairmanship could not be stormy or threatening, nor could it be a humdrum, placid affair, so it had to be what it was, the jolliest and most successful annual meeting imaginable. With Mr. Harold Beale conducting the first portion of the meeting, and Mr. Samuel Wallrock, taking over on his election for the ensuing year, presiding over an annual general meeting seemed one of the easiest jobs in the world. But this was largely due to the way they held the reins—to methods as distinct and separate as the poles, but both equally successful, and the large gathering had the satisfaction of carrying out the vast amount of real business in a most enjoyable manner. All the required ingredients for fireworks were there—three proposed alterations of rules, over which there were decided differences of opinions, and several fancied grievances over policy and competitions—but not even a damp squib resulted. Everyone was happy, on occasion, hilariously so; and even the member who took his personal desires most seriously went home feeling that all was pretty well with the best of all Societies, to wit, the National Sweet Pea Society.

During his year of office, Mr. Harold Beale has done much for the Society. At both of the shows he entertained the members most generously and well. Immediately before the Annual Meeting he lunched all who cared to come, and very many did. The famous establishment of Messrs. Carter and Co. was open to inspection and many were impressed by its extent and efficiency. Early in the season, Mr. Harold Beale, in his endeavours to increase the membership, had printed and circulated 20,000 folders relating to the Society. He also designed a new and beautiful certificate in natural colours for the Affiliated Societies, and gave the Society a three years' supply. In many ways, not overlooking the value of his personality, he served the Society splendidly, but in none was it more valuable than his happy manner of extending that good nature and fellowship among the members which continued throughout the meeting.

The Committee's Report and Balance Sheet, which were printed and circulated, show the affairs of the Society to be in a gratifying condition. As we have implied, two shows were again held during the season and, both in London and at Norwich, magnificent Sweet Peas were staged. Mr. William Huffey, of Tonbridge, achieved the difficult task of winning outright the *Amateur Gardening* Challenge Cup. Last year he won outright the Hawlmark Cup.

But on the morning of the meeting the Society received, with intense regret, news of the sudden death of Mr. Huffey from heart failure following an accident while on holiday. The meeting stood in a silent vote of sympathy and remembrance. The Report records the great services of Messrs. Robert Bolton and Son, who grew, free of charge, excellent trials of Novelty Sweet Peas, and also most generously entertained the Committee and many members who visited them. There has been a large increase in membership during the year under review.

As Honorary Treasurer, Mr. J. M. Bridgeford, again presented an excellent Balance Sheet, which shows a surplus of £69 6s. for the year, and he explained it, drawing comparisons with the previous year's statement, in a most interesting and lucid manner Small wonder that Mr. Bridgeford was re-elected with enthusiasm.

The Floral Committee's Report, read by Mr. C. H. Curtis, was another record of excellent work, and this also appealed to the members. Mr. Curtis also read the report of the Henry Eckford Memorial Trustees, and his announcement that the fund was now in such a good financial condition that no further appeals for donations would be necessary, was very gratifying. The Trustees' award of the Gold Medal for the year to Mr. Hugh Dickson was very popular.

Then came a most happy interlude which had the full approval and enthusiastic support of the meeting. The Society's President holds office for only one year and to succeed Mr. Harold Beale, the meeting was given the name of Mr. Samuel Wallrock, of The Manor House, Stanmore, Middlesex, who is so well-known as an amateur gardener with an especial love of Sweet Peas, with which he has been particularly successful this year. There was no question as to the wisdom and popularity of the Committee's nomination of Mr. Wallrock, for he was elected with great enthusiasm. His first duty, on taking the chair, was the presentation, on behalf of the Society, of its Gold Medal and a framed autographed copy of the large group photograph taken at the Norwich Show. This Mr. Wallrock did most felicitously, and Mr. Harold Beale received an immense ovation with the gifts.

The change of Chairman of Committee provided another opportunity for the meeting to express their appreciation of great work and unrestricted sacrifice of time in the Society's service by the retiring Chairman, Mr. F. J. Rogers, whose home is in the Isle of Wight.

The Secretary informed the meeting that Mr. Rogers had attended every meeting of the General Committee, and that he estimated Mr. Rogers's mileage in this service to be almost two thousand. The election of Mr. George H. Burt, grower to Messrs. E. W. King and Co., at Coggeshall, Essex, who has long been known as one of the Society's keenest and most hard-working members, as Chairman of Committee, was also exceedingly popular. On the proposal of the retiring Chairman, and seconded by a past Chairman, both of whom were very complimentary, Mr. A. C. Bartlett was unanimously re-elected Secretary. There were three vacancies on the General Committee, but in view of the popularity of their nominations, the meeting decided to elect the following eight members:—Mr. F. J. Rogers, Mr. A. W. Gower, Mr. F. Stratford, Mr. G. H. Bard, Mr. E. H. Starling, Mr. F. Cotterill, Mr. A. Abbott and Mr. W. H. Holloway.

The scrutineers announced that the ballot for nine seats on the Floral Committee had resulted in the election of the following:—Amateurs: Mr. E. H. Christy, Mr. F. J. Rogers, Mr. C. H. Curtis, Mr. W. Humphrey and Mr. C. Ball. Trade: Mr. G. H. Burt, Mr. D. Allan, Mr. A. Ireland and Mr. E. R. Janes. The Editor of the Sweet Pea *Annual*, Mr. J. S. Brunton, was re-elected, and thanked heartily for his long services, and the Auditors and Provincial Corresponding members of Committee were re-elected.

Under "any other business," Mr. C. D. Richardson appealed for more consideration in seats on the Committee and in the schedule of prizes for the metropolitan members. He was informed that on several occasions the schedules had contained classes such as he advocated, but there was no competition in them. With regard to the Committee, he was given the names of several metropolitan members and asked for a further nomination, but this was not forthcoming.

The judges of the Essay Competition announced that the three prizes had been awarded to Mr. George de la Perrelle, Easton-in-Gordans, Somerset; Mr. John A. Strickland, Gunness, Lincolnshire; and Mr. Thomas Baines, Marks Tey, Essex, in the order named.

In acknowledging the vote of thanks for presiding, Mr. Samuel Wallrock said it had given him the greatest possible satisfaction, and he felt convinced that having experienced the hearty goodwill and fellowship there was in it, the Society was bound to go on and prosper. The retiring President, Mr. Harold Beale, entertained the members to tea, and so ended the most successful and enjoyable Annual Meeting of the Society.

NEWCASTLE SHOW.

Undoubtedly the finest exhibition of fruits, flowers and vegetables that has ever taken place in Newcastle was that held on October 9 to 12. The show was organised by the *Evening World* and staged in the Pavilion, at the North-East Coast Exhibition. This is the third and concluding exhibition organised for the furtherance of horticulture in the north-east counties, and the appreciation of the public was reflected in the attendance; more than 25,000 people paid for admission.

This autumn show was originally intended for vegetables and flowers but, ultimately, some seventy fruit classes were added, and these classes not only brought keen competition, but the quality of the fruits throughout was remarkable. The vegetables, as was expected, attracted the pitmen of the north-eastern counties. The number of exhibits was enormous. In the classes for Leeks there were over one-hundred-and-fifty entries, the first prize in each class being £15. The collections of vegetables were of great merit, as also were the single-dishes which occupied buildings especially erected for their accommodation outside the Pavilion.

The fruit classes were in many respects similar to those held in the past by the Three Northern Counties Fruit Conference. In the class for six dishes of ripe fruits (open), Major C. Bewick (gr. Mr. W. E. Anderson), Close House, Wylam, was first, with good bunches of Muscat of Alexandria and Mrs. Pince Grapes, Belgrade Peaches, Doyenné Bussock Pears and Apples Cox's Orange Pippin and Allington Pippin; second, H. Deverell, Esq.

Mr. C. J. Dillon, Springfield Nurseries, Pontiland, showed the best two bunches of black Grapes; second, Major Bewick; and third, Mr. W. St. Howard, Wickham. For two bunches of white Grapes, Mr. J. A. Jones, Gallow Hill, Morpeth, led with good bunches of Muscat of Alexandria; Mr. T. Mytton, Blagdon, second; and Major Bewick, third, all showing the same variety.

The best six dishes of dessert fruits, not fewer than four kinds, were staged by Major Bewick, who also showed the leading nine dishes of Apples, six culinary and three dessert, and three dishes of Pears; his Pitmaston Duchess and Souvenir de Congrés Pears were very fine.

In the class for twelve dishes of Apples, distinct, Lady Rayleigh (gr. Mr. E. McLaren), Beaufort Castle, Hexham, was first, with grandly coloured fruits; Major Bewick was second; while for six dishes, distinct, dessert, Lady Rayleigh again led. In the class for six dishes of culinary Apples, Major Bewick scored, his Peasgood's Nonesuch, Rev. W. Wilks, Queen and S. T. Wright being very fine; Mr. Hodgson, Carlisle, was second, and Mr. J. Garbutt, Burney Hall, Throckly, third.

The competitive Floral Section was well filled, and some remarkably fine hardy flowers were shown. Grand Roses were shown in the class for twenty-four blooms not fewer than twelve varieties, in which Mr. T. Carrack, Greenside, was placed first, his best flowers being of Golden Emblem, G. Dixon, Mrs. C. Lamplough and Earl Haig.

Mr. Carrick also led in the classes for twelve and six Roses. For three vases of Dahlias, Mr. T. Matton received the premier award, while the best six vases of Chrysanthemums, three stems in each vase, were shown by Lady Allendale (gr. Mr. J. Thomas), Bywell Hall, Stocksfield.

The trade groups were exceptionally good. Messrs. Finney had a very fine collection of vegetables, artistically arranged, for which they received a Gold Medal. Similar awards were made to Messrs. R. V. Rogers, Pickering, who had Roses and hardy border flowers arranged artistically; Messrs. Kent and Brydon, for a grand collection of Potatos; Messrs. Michie, Alnwick, for a fine collection of Apples; and Messrs. Lawrenson, for a cottage garden design.

ROYAL HORTICULTURAL.

FOURTH AUTUMN SHOW.

October 23 and 24.—The fourth, and last, of the series of Autumn Shows, which was held in the new Horticultural Hall, Westminster, on these dates, was "chiefly for Orchids and Stove and Greenhouse Plants." Orchids were there in large groups of considerable beauty and excellence, and there was one magnificent group of stove and greenhouse plants, but beyond these the show resolved itself into one of autumn foliage and ornamental fruits, for such exhibits seemed to dominate the show, and they illustrated splendidly the great autumn garden value of many trees and shrubs. The Orchid Committee recommended one First Class Certificate and seven Awards of Merit to novelties. The Floral Committee recommended nine Awards of Merit to new and rare plants and shrubs. Although a large number of seedling Apples was submitted to the Fruit and Vegetable Committee, none was considered to be of sufficient merit to warrant an award.

Orchid Committee.

Present: Mr. Lionel de Rothschild (in the chair), Mr. Gurney Wilson (Hon. Secretary), Prince Shimadzu, Mr. Fred J. Hanbury, Colonel Stephenson Clarke, Mr. R. G. Thwaites, Mr. E. R. Ashton, Mr. Stuart Low, Mr. T. Armstrong, Mr. J. Cowan, Mr. Robert Paterson, Mr. W. Hatcher, Mr. Charles H. Curtis, Mr. J. E. Shill, Mr. H. H. Smith, Mr. S. Flory, Mr. A. Dye, Mr. J. Wilson Potter, Mr. F. K. Sander and Mr. H. G. Alexander.

First Class Certificate.

Brasso-Laelio-Cattleya Ambaurea (*B.-L.-C. Amber* × *Cattleya aurea*).—Another gloriously beautiful hybrid from Dell Park, and a grand addition to the fine series of yellow hybrid Orchids from this collection. The flowers are of fair size, well expanded, and of good shape. The sepals and petals are a lovely shade of rich, soft yellow, while the lip is deeper yellow with a waxy rim of cerise and some reddish markings at the apex and in the throat. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Awards of Merit.

Laelio-Cattleya Cassandra, Melchett var. (*L.-C. Sargon* × *L.-C. Gladiator*).—A very large-flowered hybrid with widely-expanded, flattish blooms. The sepals and petals are purplish-mauve, with deep mauve veins down the centre. Lip wavy, the side lobes overlapping the column, deep purple, with an old gold-veined throat. Shown by Lord Melchett (Orchid-grower, Mr. A. Ruck), Melchet Court, Romsey.

Habenaria Lugardii.—An extremely interesting and distinct Orchid collected in the Congo region. The leaves are large, flat, wide and spread out at the ground level. The flower stem is about eighteen inches high, erect, pale green, with lance-shaped, paper-like bracts. This bears a head of white and green flowers, each flower developing a slender, greenish-white, pendent spur fully eight inches long, transparent, and containing nectar or moisture that is parted at intervals by air, as in a thermometer when the mercury column is broken. Shown by Messrs. Sanders.

Laelio-Cattleya Cavalese var. Excelsa (*L.-C. Lustre* × *Cattleya Fabia.*).—In this charming variety the sepals and petals are of clear, bright mauve colour, and the large, rounded and waved lip is royal purple, shaded with ruby near the gold-veined throat. Shown by Messrs. H. G. Alexander, Ltd.

Brasso-Cattleya British Queen, Stonehurst var. (*B.-C. Digbyano-Mendelii* × *Cattleya Lord Rothschild*).—In this very attractive variety the flowers are of light, clear mauve colour, except for a large, soft yellow area in the throat, this colour shading into a diffused, whitish ring. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Miltonia pulchra var. Enchantress (*M. William Pitt* × *M. Lycaena*).—A neat and beautiful hybrid with shapely flowers; the sepals and petals are deep rose colour, redder at the base and paling towards the tips. The wide lip has a well-defined, reddish-brown mask, with a band of white around it, the large apical part of the lip being soft rose, with white shading. Shown by Messrs. Charlesworth and Co.

Cattleya Gloriette var. The Node (*C. Tityus* × *C. Hardyana var. Warneri*).—A large and handsome variety, with rosy-mauve sepals and petals and a very big lip that is of rich, royal purple colour, with a golden, purple-veined throat. Shown by Mrs. Carl Holmes (gr. Mr. W. J. Penton), The Node, Welwyn.

Cycnoches Loddigesii.—A quaint old large-flowered species in which the male flowers are wide, deep dull green, mottled with darker green or brownish-green; the lip is greenish-white. Shown by Mr. C. S. Garnett, The Strand, Derby.

Challenge Cup Competitions.

The Schröder Challenge Cup, for the best group of Orchids staged by an amateur, was awarded to F. J. Hanbury, Esq. (gr. Mr. S. Barnes), who had a beautiful group, resplendent with rich colouring. It contained Miltonias and Cypripediums in variety; Laelio-Cattleya Ishtar, Brockhurst variety, very fine, and L.-C. Valencia, together with several Laelio-Cattleya seedlings of merit, and especially good specimens of Cattleya Thomasii and C. Muriel Henderson.

Three exhibits were staged in the competition for a group of Orchids on a space not exceeding sixty square feet, and the Challenge Trophy was deservedly awarded to R. Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, whose group was tastefully arranged and contained excellent specimens of Vanda coerulea and V. Luzonica; Cattleya Thebes, Stamperland variety; various Odontoglossums and Cypripediums; Laelio-Cattleya Profusion, L.-C. P., Stamperland variety, L.-C. Mrs. Meda, L.-C. Walter Gott, and various other beautiful Orchids.

J. J. Joicey, Esq. (gr. Mr. J. Mackay), The Hill, Whitley, Surrey, was second, his best specimens being of Vanda coerulea, Cattleya Honoria, C. Hardyana, C. Moira and C. Eleanor var. alba; Laelio-Cattleya Senate, L.-C. Don Juan and L.-C. St. Gothard, and Brasso-Cattleya British Queen var. Admiration. The Rt. Hon. Lord Melchett (gr. Mr. W. Petty), Melchet Court, Romsey, who was third, showed Oncidium varicosum, Cattleya Fabia, C. Enid var. alba, C. Mendelii, C. Bowringiana and C. Hesperus; Laelio-Cattleya luminosa var. aurea and L.-C. Fame, with various Cypripediums in good condition.

Gus Mayer, Esq. (gr. Mr. R. Cottam), Wistler's Wood, Woldingham, Surrey, was the only exhibitor in the amateurs' competition for twelve Orchids. His specimens were of Mormodes Buccinator var. lutea aurea; Odontoglossum Zenon var. Isobel, Vanda coerulea and V. suavis; Cattleya Mantinii, Oncidium Forbesii, Vuylstekeara elatior var. Lord Rothermere, Cypripedium bellatulum, Sophro-Laelio-Cattleya Dora, Laelio-Cattleya Ivanhoe, Cattleya Portia and Oncidium varicosum var. Rogersii.

Groups.

Although the Orchid growers had to wait until the last of the Society's Autumn Shows, they rose magnificently to the occasion, with the result that, although the Orchids did not dominate the show, they were quite a big feature, and several grand groups were staged.

Messrs. Sanders showed a very extensive collection which embraced numerous types and varieties. Especially fine Cattleyas were C. Fabia vars., C. Majestic, C. Orietta, C. Brightness, C. President Wilson, the delicately coloured C. Prince John, and C. Mrs. Herbert Greaves. They had graceful Dendrobiums in variety; several splendid specimens of Oncidium bicallosum, O. tigrinum, the dainty O. ornithorynchum, and the giant-sprayed O. varicosum var. Rogersii. Odontoglossum grande and O. Catherine, and various Odontiodas were shown well, together with such Laelio-Cattleyas as L.-C. Fame and L.-C. Carmania var. Minnewater, and Brasso-Cattleya Crofutiana. Among interesting and rather uncommon subjects displayed in this fascinating group were Habenaria Lugardii, Vanda Kimballiana and V. Sanderiana, Brassavolla cordata, Masdevallia trochilus, Cirrhopetalum longissimum and C. Rothschildianum, Dendrobium eriaflorum, Pleione Wallichii, Doritis pulcherrima and Catasetum Gnomus var. They also staged numerous Cypripediums.

Another grand and very extensive group was that set up by Messrs. Charlesworth and Co., who made special features of Oncidium varicosum, and Odontoglossum crispum var. xanthotes, showing many grand specimens of these. They also showed Oncidium splendidum, O. Forbesii and O. Cebollita, in fine form, together with Brasso-Laelio-Cattleya Priapus, B.-L-C. Xanthea, B.-L.-C. Mercia; Brasso-Cattelya Penelope, B.-C. Alfred Dean, and Laelio-Cattleya Luminosa. Among Cattleyas, outstanding sorts were C. Falco and C. Hardyana. The above represent but a small selection from among the best of the Orchids shown by this famous firm.

Smaller than the two preceding exhibits, but equally as fascinating, was that staged by Messrs. J. and A. McBean, whose special feature was a grand specimen of Laelio-Cattleya Queen Mary, with four magnificent flower trusses, carrying fifteen blooms in all. Odontoglossums were also prominent in this group, among those noted being O. majesticum, O. Figaro, O. Ovidius, O. crispum, O. Laurentia, O. Olympus, O. plumptonensis and O. ardentissimum. Vanda coerulea was included, also Cymbidium Hanburyanum var. excellens and C. H. var. Ruby. Cattleyas included C. mirificum, C. aurea C. Daedalus and C. Princess Royal, while noteworthy Laelio-Cattleyas were L.-C. Serlotha, L.-C. Valencia, L.-C. Warrior, L.-C. Hassallii var. alba, L.-C. Profusion var. Laurentia, and L.-C. Serveno. There were several fine Brasso-Cattleyas, Miltonias and other Orchids in this interesting group, including many plants of the dwarf and brilliantly coloured Sophronitis grandiflora.

Cattleyas and Laelio-Cattleyas were specially prominent in the group set up by Messrs. H. G. Alexander, Ltd., who also had many fine specimens of Oncidium varicosum var. Rogersii in the background. Prominent Laelio-Cattleyas included L.-C. Hilary, L.-C. Berenice, L.-C. Cavalese, L.-C. Queen Mary var. Gloriana, L.-C. Hilary var. Majestica, L.-C. Moloch var. Vesuvius, and L.-C. Ishtar var. sanguinea; while specially good Cattleyas were C. Fabia, C. Dragon, C. Dorothy Tucker and C. Princess Royal. They showed a good specimen of Zygopetalum Mackayi and numerous Cypripediums.

Messrs. Cowan and Co., besides showing Cypripediums in variety, had attractive specimens of Vanda coerulea, Odontoglossum grande, Coelogyne Mooreana, and various Cattleyas, including C. Daedalus, C. Gloriette, C. Ardens, C. Lady Veitch, C. Snowdon, C. Priscilla var. alba, C. Mantinii and C. Desdemona. Laelio-Cattleya Canberra was also worthy of note.

An extremely attractive group was set up by Messrs. Stuart Low and Co., who included many grand Laelio-Cattleyas, notably L.-C. Alex, L.-C. Cantab, L.-C. Crowborough and L.-C. Mrs. Meda. Grand Cattleyas included C. Gatton Ruby, C. intertexta var. alba, C. Arnaeus, C. Xanthus, and C. amabilis var. alba, while this beautiful Brasso-Cattleya British Queen, B.-C. Minerva and B.-C. General French, were also very fine. Cypripediums in variety were included, together with Oncidium Lanceanum and O. bicallosum, Phalaenopsis Esmeralda and Stanhopea occulata.

Messrs. Sutton Bros. staged a small but choice collection of various Orchids, as also did S. G. Brown, Esq., Brownlands, Shepperton, who had, among others, good flowering specimens of Epidendrum vitellinum, Oncidium varicosum var. Rogersii, O. pulvinatum and O. grande; Maxillaria lepidota, Selenipedium macrochilum. Mormodes Buccinator and other choice subjects.

Mr. J. Evans showed numerous good Orchids, including a fine specimen of Epidendrum vitellinum var. majus, Miltonia Bleuana var.

gigantea, Vanda coerulea var. regalis, Cypripedium Maudiae, Odontioda Euterpe and Oncidium varicosum var. Rogersii.

In the charming group set up by E. R. Ashton, Esq. (gr. Mr. C. V. Kent), Broadlands, Tunbridge Wells, outstanding and interesting sorts included Brasso-Laelio-Cattleya Mercia, Broadlands variety; Laelio-Cattleya Profusion, L.-C. Cavalese, L.-C. Sofrana and L.-C. luminosa var. citrina; a grand specimen of Stenoglottis fimbriata with seven graceful flower spikes; the richly coloured Lowiara insignis, various Cypripediums, and several other good sorts. A very interesting collection.

Messrs. Harry Dixon showed Cypripediums in variety, together with Odontoglossum amabile, Cymbidium Orion, Pleione Lagenaria, Cirrhopetalum ornatissimum and various Cattleyas and allied genera.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. Arthur Turner, Mr. James B. Riding, Major George Churcher, Mr. W. B. Gingell, Mrs. Ethel M. Wightman, Mr. C. F. Langdon, Mr. J. T. West, Mr. Courtney Page, Mr. R. Findlay, Mr. B. Long, Mr. Hugh Dickson, Mr. William Howe, Mr. D. B. Crane, Mr. Charles E. Pearson, Mrs. Helen Lindsay Smith, Mr. G. W. Leak and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. E. A. Bowles, Mr. G. Reuthe, Mr. W. Irving, Mr. Amos Perry, Mr. L. R. Russell, Mr. A. Bedford, Mr. Reginald Cory, Mr. Mark Fenwick, Mr. E. H. Wilding, Mr. Hiatt C. Baker, Mr. T. W. Taylor, Mr. F. G. Preston, Mr. T. Hay, Mr. G. Yeld, Sir William Lawrence, Bt., Miss E. Willmott and Mr. N. K. Gould, Secretary.

Awards of Merit.

Chrysanthemum Arabella.—A market-sized Japanese variety with broad florets of pinkish-mauve colour.

C. Dazzle.—A highly decorative Pompon Chrysanthemum which, although, perhaps, a trifle larger than satisfies the critical, has great garden value. The colour is a light crimson-maroon which pases to a dark old-rose colour and the tips of the florets become yellow.

C. Florence Bigland.—A good market-sized Japanese variety of rich golden-yellow colour. The above varieties were shown by Mr. H. Shoesmith, junr.

C. Red Cavell.—This is an incurving Japanese variety of exhibition size, made up of broad florets of bright chestnut colour and a golden reverse. Shown by Messrs. Keith Luxford and Co.

Cotoneaster multiflora var. callicarpa.—Although the award was given to this as a berried shrub, it is also very attractive when in flower during the late spring and early summer. It is of graceful habit and bears small, ovate leaves and free clusters of large, dark red fruits. Shown by Sir William Lawrence, Bart., Burford, Dorking.

Euonymus lancifolia.—This handsome Spindle Tree was densely set with pale rose-coloured fruits which contained scarlet seeds. Shown by the Director, Royal Gardens, Kew.

Gladiolus sp.—The award is subject to the species being named. A long spike bearing twenty-four fully expanded, medium-sized, soft pink-coloured flowers, which have a narrow carmine line on each of the two lower segments, was shown by Collingwood Ingram, Esq., Bevenden.

Gordonia axillaris.—The tender shrub shown under this name bore several large white flowers very suggestive of those of a Romneya. The flowers, which were solitary or in pairs, measured nearly six inches across, and had handsome clusters of rich golden stamens. The long, stout leaves are oblong-lanceolate and lightly serrated. Shown by Major L. Johnston, Campden.

Taxus baccata fructu-luteo.—This form of the common Yew bears large, pale orange-coloured fruits which are very attractive. Shown by the Director, Royal Gardens, Kew.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. J. Cheal, Mr. W. H. Divers, Mr. E. Beckett, Mr. A. Poupart, Mr. W. Poupart, Mr. H. V. Taylor, Sir W. Lobjoit, Mr. A. W. Metcalfe, Mr. E. Neal and Mr. A. N. Rawes, Secretary.

Many seedling Apples were exhibited before this Committee but none was considered an improvement on existing varieties, although it was suggested that a seedling Cox's Orange Pippin, shown by Mr. A. Worsley, Isleworth, be sent to Wisley for comparison.

Group.

Sir Mayson Becton (gr. Mr. K. W. Kent), Highlands, nr. Weybridge, showed excellent fruits of Apples and Doyenné du Comice Pears, grown on the "poor soils of the St. George's Hill district, Surrey."

⁂ The report of this show will be concluded in our next issue.

READING GARDENERS.'

There was an excellent attendance at the fortnightly meeting held on Monday, October 7. The lecturer was Mr. C. Cook, gardener to Mr. A. C. Bartholomew, Tilehurst Road, Reading, and his subject was, "The Propagation of Alpines and Rock Plants." He gave most useful and valuable hints on soils, and quite an original talk on the raising of these most beautiful and interesting plants from seeds, cuttings and divisions. The principal genera dealt with were Alyssum, Arabis, Arenaria, Dianthus, Daphne, Gentiana, Geranium, Lithospermum, Lychnis, Phlox, Saxifraga, Silene and Violas.

An interesting discussion followed, sustained by Messrs. Young, Reed, Howlett, Balcombe, Cox, Goddard and Broomfield. At the close a very hearty vote of thanks was passed to Mr. Cook on the proposition of Mr. F. Townsend, who referred to the valuable information given by the lecturer.

In the competition for three vases of early-flowering Chrysanthemums, distinct, the first prize was gained by Mr. E. Blackwell, The Gardens, Foxhill, Reading, the second by Mr. H. Goodchild, The Gardens, Queen Anne's School, Caversham, and the third by Mr. W. Brinsdon, The Gardens, Mount Warren, Mapledurham. For three vases of Michaelmas Daisies, distinct, Mr. F. Haines, The Gardens, Calcot Hanger, was successful in gaining the first prize, and Mr. H. G. Cox, Hamilton Road, Reading, followed closely for second prize.

In the non-competitive section, an Award of Merit was granted to Mr. W. Hullcoop, Peppard Road, Caversham, for a pretty exhibit of Roses. For so late in the season, there were two excellent lots of Sutton's Prizewinner Runner Beans. One was exhibited by Mr. A. W. Gower, The Gardens, Calcot Grange, who had been picking from the same row since the second week in June, and the other by Mr. H. Goodchild, who has been picking since the commencement of July. The Beans averaged fourteen inches in length.

AUSTRIAN HORTICULTURAL.

As usual, the occasion of the annual autumn fair in Vienna was also that of the horticultural exhibition, which was in no way behind its predecessors, and in many ways marked an advance. Formerly, in the part under cover, Dahlias, hardy plants and pot plants have greatly predominated, but Cacti are now coming more and more to the front. Indeed, so great is the demand for these plants, and so eager the response on the part of the growers, that it is to be hoped that the demand will continue to increase, otherwise the supply will be found to be excessive. Hardy plants also enjoy an ever-increasing popularity in Vienna, and the same may be stated of Dahlias and Roses.

The exhibition halls were beautifully decorated and arranged. At the entrance was the Dahlia display of the firm of Wilhelm Debor, which has the same position every year but knows well how to create variety in the staging. The two pavilions between which the Dahlias were displayed were this year occupied, the one by the garden plans and the other by the vegetable group of the local Gardeners' Union. The Hollandia Nurseries showed Conifers which, though in excellent condition, showed signs of the hard winter through which they had come. Close by were the rock gardens, among which was noted one from the Hortensium girls' and boys' school. An interesting, although somewhat melancholy, display was that of the landscape gardener appropriately named W. Sterba, of Atzgersdorf; in half-circle formation was a number of graves, tastefully and artistically decorated.

In the open was a well-arranged group of succulent plants from the well-known firm of Leopold Dücke, opposite a fine collection of Palms shown by the Vienna municipality, which also had a pretty garden adorned with various flowers and flanked by a brick wall. This group, with the Dahlia collection of Debor and the hardy plant garden of the firm of Strauss, Windmühlhöhe, represented the best features of the open-air portion of the exhibition. Much interest was shown in a so-called "week-end" garden, complete with hardy plants, espalier fruit trees, pool, and seats, shown by the landscape firm of Otto Trenkler.

Dahlia novelties were a feature of the exhibition, and among others shown by the firm of Rath, were Frau Jety Walter (bluish Show Dahlia, with some white), and Sapanow (blood-red); by Pospischil an unnamed strawberry-coloured variety, of the form of Andreas Hofer, and a variety named Johann Strauss, a yellow Show Dahlia of great durability.

CARDIFF GARDENERS'.

The first fortnightly meeting of the above Association was held on October 1, at the Queen's Hotel, Cardiff, Mr. W. H. Puyce being in the chair. An expression of regret was passed by all members standing, at the death of one of the oldest and original members of the Association, Mr. R. Mayne, who had passed away after a severe illness.

The lecturer for the evening was Mr. Wilfrid Evans, of the Hardy Plant Nursery, Llanishen, whose subject was "Some Plant Peculiarities." Among native plants the lecturer brought to notice were the common Primrose, Sundew, the Field Orchids and Arums; while garden flowers he mentioned included the Salvias, Figwort and Burning Bush.

Prizes were offered for collections of nine Roses. Mr. J. Jones secured the first prize, Mr. Wilkins, second, and Mr. Folm, third. For a vase of early-flowering Chrysanthemums, the first prize was won by Mr. W. Webber, while Mr. J. Jones showed the best vase of garden flowers.

WIMBLEDON GARDENERS'.

The first meeting of this Society's session for 1929-30, took place at Queen's Hall, Wimbledon, on October 9. The hall was crowded, every seat being occupied. Mr. A. Hosking, of the John Innes Horticultural Institution, Merton Park, presided, and introduced the lecturer, Mr. William Cross, to the members.

Mr. Cross announced that his subject was to be "Flowers and Their Servants." The lecture was beautifully illustrated by a large number of lantern slides consisting of many coloured and black and white photographs, as well as diagrams. As the lecture proceeded the audience sat spell-bound, and at the conclusion gave Mr. Cross a great ovation. Mr. W. Price, in a neat little speech, proposed a vote of thanks, emphasising the fact that every detail of the lecture was perfectly plain. This was carried by acclamation, and after the Chairman had announced that Mr. J. Coutts, Assistant Curator, Royal Gardens, Kew, would, on October 23, lecture on "Roses," the meeting closed.

Obituary.

Jules Daveau.—We note, in the October issue of our French contemporary, *La Revue Horticole*, an announcement of the death on August 24, at the Montpellier Botanic Garden, of M. Jules Alexandre Daveau, Curator of the garden since 1893. He began his career at the age of fourteen, in 1866, in the Paris Botanic Garden, where he eventually became head of the seed laboratory and experimental garden. He then travelled abroad, becoming in 1876 Director of the municipal Botanic Gardens of Lisbon, where he gained considerable distinction. He was a prolific writer in the horticultural and scientific press, and was a correspondent member of the Lisbon Scientific Academy. He had received a number of honours, including the ranks of Officier de l'Instruction Publique, Officier du Mérite Agricole, and Commandeur du Christ du Portugal.

Gilbert Martin.—We learn with regret of the recent death of the veteran French horticulturist, M. Gilbert Martin, of Digoin (Saône-et-Loire), at the advanced age of eighty-four years. He was the originator of the now well-known race of Star Dahlias known as Etoile Digoinaise; the nursery is being efficiently carried on by his eldest son, M. Louis Martin, who succeeded to the management of the business on the retirement of his father.

ANSWERS TO CORRESPONDENTS.

Clapp's Favourite Pear.—*H. W.* It is a general complaint against Clapp's Favourite Pear that it decays at the core. The fruits should be eaten so soon as gathered, and should be gathered at intervals before they become yellow, otherwise they speedily decay. Give the tree a good dressing of old lime-rubble and point it well into the soil.

Codiaeum Leaves infested with Scale.—*W. G. B.* Your Codiaeums (Crotons) are badly infested with freshly emerged nymphs of the brown scale, Lecanium hesperidum. Both surfaces of the leaves should be sponged with a one per cent. solution of Volck. The cause of the dying-back and brown spotting of the foliage is due to some error in cultivation, such as the amount of water received at the roots, and overhead syringing during the cooler and cloudier weather recently experienced. Careful attention should be given to the water requirements of these plants in order to preserve a correct balance between roots and leaves.

Coloured Bean Pods.—*L. W. C.* The Waxpod and Golden Butter Beans frequently sport and give pods of different hue; if Black Striped and Waxpod are grown together, and cross fertilised by hand, the resulting seedlings give red-marked pods. One of our correspondents has selected no fewer than eight distinctly coloured forms and these now appear to be fixed.

Erecting Greenhouses.—*J. E. W.* Greenhouses for the cultivation of plants should be run from north to south.

Lily-of-the-Valley Diseased.—*K. L. J.* The Lily-of-the-Valley plants have been killed by the fungus Botrytis cinerea. All infected plants should be destroyed and the bed remade, adding well-decayed leaf-mould. Water the ground with Cheshunt compound before planting and again in spring. Dust the crowns with flowers of sulphur prior to planting.

Melons Unhealthy.—*A. C. W.* The leaf sent was completely dry on arrival. Your trouble may have been caused by an excess of water and atmospheric moisture, and too little ventilation after the fruits were set and swelling; or it may have been due to lack of bottom-heat towards the finish. A brisk bottom-heat should always be maintained at this stage, and tepid water only given in reduced quantities. The other leaf sent is that of a Hoya, possibly H. carnosa, the species most frequently grown.

Names of Fruits.—*T. S. D.* 1, Queen; 2, and 6, Bismarck; 3, Lord Derby; 4, unknown; 5, Warner's King; 7, probably Dr. Hogg, but stem broken off in packing.—*B. M. W.* 1, Comte de Lamy; 2, both fruits decayed; 3, Louise Bonne of Jersey 4, send better specimens when in season; 5, Cox's Pomona; 6, Farleigh Damson.—*E. M.* 1, Ribston Pippin; 2, Small's Admirable.—*H. W.* 1, Schoolmaster; 2, Small's Admirable; 3, Rhode Island Greening; 4, not recognised; 5, Pear No. 2, Broompark.—*C. A.* 1, Rosemary Russet; 2, James Grieve; 3, Yorkshire Beauty.—*E. G.* 1, Fearn's Pippin; 2, Allington Pippin; 3, probably Byford Wonder; 4, Winter Majetin; 5, Lane's Prince Albert; 6, possibly Lord Rosebery; 7, Minchull Crab; 8, Rymer; 9, Blenheim Pippin; 10, Catillac; 11, Magnate; 12 and 18, Pitmaston Duchess; 13, Triomphe de Jodoigne; 14, Dumelow's Seedling; 15, Beauty of Kent; 16, Winter Hawthornden; 17, Durondeau; 19, Maguate; 20, probably Beurré Baltet Pére; 21, Marie Louise; 22, not recognised, send when in season; 23, Brown Beurré; 24, Beurré Bachelier; 25, Louise Bonne of Jersey; 26, Souvenir de Congres.—L. E. Apparently Black Hamburgh, but fruits were too badly damaged to permit of proper identification. —*G. C.* Red, Worcester Pearmain; green, Dumelow's Seedling.—*A. D. H.* Mank's Codlin.—*W. C.* Your fruit was too perished to be recognised.—*A. H. D.* Your fruit arrived completely smashed.

Names of Plants.—*J. E. I.* Stag's Horn Sumach, Rhus typhina.—*A. and M.* Sedum reflexum.—*G.* 1, Aster hybrid, impossible to name without seeing plants, as flowers were withered; 2, Epilobium, probably E. angustifolium; 3, Aster hybrid (see No. 1); 4, Colchicum, probably C. speciosum var. album, flower rotten; 5, Crocus speciosus var.; 6, Aster Climax; 7, Clematis globosa.—*C. E. M., Hunts.* A form of Nicotiana sylvestris.—*R. M.* Nicotiana rustica var.—*J. C.* Cypripedium barbatum; 2, not recognised; 3, Lycaste aromatica; 4, Cypripedium cardinale.—*G. C.* A garden variety of Wallflower (Cheiranthus). *H. B. S.* 1, Veronica Guthriana; 2, Campanula pusilla; 3, Sedum spurium; 4, Cotyledon simplicifolia; 5 and 7, Sedum rupestre; 6, Dianthus deltoides var.; 8, Saxifraga cuneifolia; 9, Sempervivum arachnoideum var.; 10, Androsace species, send in flower; 11, Ajuga reptans var. atropurpurea; 12, Antennaria dioica. —*A. T. J.* Sedum anopetalum, D.C., South Europe.—*J. B.* Araujia sericifera (syn. Physianthus albens).—*C. T.* Your specimen is the ordinary Quince.—*A. C. W.* 1, Tillandsia species, cannot name without flowers; 2, Hibiscus syriacus var.; 3, Liriope spicata var. variegata; 4, Origanum Majorana.—*R. L. H.* Gleditschia triacanthos, "Honey Locust." *A. J. B.* Linaria vulgaris.—*F. F.* 1, Aegle sepiaria; 2, Tecoma species; send when in flower.—*A. J. S.* Achillea filipendulina.—*C. H. P.* Jacobinia carnea. *H. B.* Ophiopogon Jaburan var. variegatus.—*W. S. Woking.* Diosma ericoides.

Popular Pink-flowered Mesembryanthemum.—*J. C.* It is possible that you refer to the pink form of the Ice Plant, M. crystallinum. M. cordifolium, with red flowers, is frequently grown.

Potato Scab.—*A. S. G.* The eruptions on the Potato are due to an attack of common or brown scab. This disease is particularly prevalent on sandy and gravelly soils, and also in alkaline conditions. The addition of grass-mowings has given good results. They should be dug in immediately prior to planting, at the rate of a barrow-load to four square yards. Dress the ground with superphosphate of lime and sulphate of ammonia in spring. Avoid planting diseased sets, and refrain from throwing the peelings from infected tubers on the manure heap.

Seedling Pear.—*Pear Pip.* We are interested to see the two Pears from the tree you have grown from a seed. As these are not yet ripe we cannot test them, but have put them in store and will let you have our opinion when they ripen.

Treatment of Winter-flowering Begonias. —*J. C.* This subject was dealt with in our issue for October 19, p. 300.

Treatment of Brassicas for Club Root.—*W. J. S.* As your ground would appear to be badly infested with club-root, and the application of quick-lime has not proved effective in preventing infection of your present crops of Brassicas, we suggest that in future you treat your plants from the seedling stage up with mercuric chloride (corrosive sublimate) which has been found to effect a good measure of control over this scourge. Sterilise all seed-beds of Brassicas, Wallflowers, etc., by watering the soil thoroughly with a solution of one ounce of mercuric chloride (use only finely-powdered material and, when purchasing it, do not confuse it with insoluble calomel or "mild mercuric chloride") in six gallons of water. Ten days after germination has taken place, water the seedlings with a solution of one ounce in fifteen gallons of water (on heavy soils one ounce in ten gallons is best), and repeat this application a few days previous to planting. When planting, dip the seedlings for a period of one minute in a solution of one ounce in ten gallons of water. In all cases, apply enough solution to thoroughly wet the soil about the roots of the plants. Corrosive sublimate is deadly poisonous and should be handled with extreme care.

Veronica rupestris v. V. prostrata.—*K. and S.*—There is considerable confusion and disagreement over the nomenclature of these Veronicas, but we see no reason for the R.H.S. stating that V. prostrata (your plant) is a misnomer for V. rupestris. The *Index Kewensis* gives V. rupestris and V. prostrata as distinct species, but in the Kew *Hand-List of Rock Garden Plants* no mention is made of V. rupestris, and V. prostrata is given as a good specific name. The late Reginald Farrer also regarded V. prostrata as a genuine species (*English Rock Garden*). He stated that it is not the same as the plant which passes under the name of V. Teucrium var. prostrata, or under the false name of V. rupestris. Consult Farrer's description of V. prostrata, it may assist in identifying your plant.

Vine Leaves Scorched.—*A. R.* The scorching of vine leaves is generally due to imperfect ventilation during the early stages of growth, when the house is heavily charged with moisture. The leaves are thin in texture for those of young vines, and suggest you have withheld or reduced your watering too soon, and this has caused premature ripening of the leaves, especially in a season like the present. Give a dressing of sulphate of potash this winter, at the rate of two ounces to the square yard; pay careful attention to ventilation next season, and see that the vines do not suffer from lack of water during the late part of the growing season.

Wallflowers with Club-root.—*I. C.* If your soil is contaminated with club-root fungus, which causes wart-like swellings or nodules on the roots of most Cruciferous plants, refrain from planting Wallflowers on the infected land, and give a good dressing of quick-lime. Mercuric chloride (corrosive sublimate) is stated to give a good control of club-root. The soil of the seed-bed should be sterilised by watering it before the seeds are sown with a mercuric chloride solution (one ounce in six gallons), and ten days after germination water the seedlings with a solution of one ounce in ten gallons. Repeat this application seven days later, and again just previous to planting. When planting, dip the seedlings for one minute in a solution of one ounce in ten gallons. (See "Treatment of Brassicas for Club Root," above).

MARKETS.

COVENT GARDEN, Tuesday, October 22, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—Chrysanthemums have been arriving in very large quantities and greatly exceeded the requirements on Saturday morning. All the outdoor blooms are now very poor in quality and difficult to clear. Carnations have shown a slight increase, but prices remain steady for good quality blooms in addition to some very good seedling varieties. The most prominent sorts are Delight, Brilliant, Eileen Low, Favourite, Circe (mauve), Hanworth Pink, Laddie, Mrs. Ward, Topsy, Spectrum, Wivelsfield White, Ivory White, and various Fancy varieties. Among Roses, white sorts are the poorest in quality. Pink, red and yellow blooms are arriving in excellent condition. Lilium longiflorum is advancing in price owing to more limited supplies; L. speciosum var. rubrum is more plentiful, with L. auratum much shorter. Arums (Richardias) are finer in quality and should be more plentiful from now onwards. Cornish Anemones and Violets are increasing in quantity almost daily, the present weather conditions being favourable to the transit of all blooms from this quarter. The first consignment of French Parma Violets arrived last week, but the Carnations from the same source were practically unsaleable on arrival. Acacia (Mimosa), Solanum berries, Chilies, Ruscus, Berberises, and Myrtles are also on sale in the French department.

Remarks.—Business conditions in the market during the past week have not been good, and although the volume of produce available has been comparatively small, prices all round, with few exceptions, are moderately low. In the hothouse Grape section, as compared with last week, there is just a shade of improvement, and the enquiry for best Peaches is moderate. In the orchard fruit sections, trade has been on the slow side, but at the time of writing there is a better tendency in the demand for good dessert Apples, while business in the cooking Apple section remains slow, except for a few parcels of top grade fruits. Hothouse Beans, after a very quiet time, are showing a slight advance in prices, in spite of the competition of Beans from Madeira. A few hothouse Potatos are selling fairly well, and a little more keenness is noticeable in the demand for new Potatos from the Azores. Mushrooms, both cultivated and field, are moderately plentiful and reasonable in price. The trade for English Tomatos is much firmer and good examples are now selling at firm prices. The green vegetable market is also showing more "life" and prices of most vegetables are now at a satisfactory level. Some Asparagus from Paris, although rather expensive, is meeting a fairly good enquiry. Salads are a good trade, and the Potato market continues on a more stable level, so far as prices and demand are concerned.

GLASGOW.

Supplies exceeding the trade demand brought about a sharp reaction in prices of Chrysanthemums last week. Cut blooms and sprays from English and Scottish growers were abundant, particularly on Friday, when varieties of the spray class were sold freely at 1d. and 2d. per bunch, while better quality sprays made up to 6d. Disbudded blooms were worth the following prices:—Pink Consul and White Thorpe, 1s. 3d. to 1s. 10d. for 6's; Le Pactole, 1s. to 1s. 9d.; Bronze Consul, 1s. 3d. to 1s. 6d.; Cranford Yellow, 1s. to 1s. 6d.; Debutante, Holicot Yellow and Holicot Bronze, 1s. to 1s. 3d.; Almirante and Sanctity, 8d. to 1s. 3d.; and Dolores, 8d. to 1s. Carnations ranged from 2s. to 3s. per dozen; pink Roses, 2s. to 3s. 6d.; and red, 1s. to 2s. 6d.; Richardias, 2s. 6d. to 3s. 6d. per bunch; Lily-of-the-Valley, small, 6d. to 1s.; large, 2s. to 2s. 6d.; Dahlias, 4d.; Michaelmas Daisies, 4d. to 6d.; and Calendula, 2d.

In the fruit market an increasing business was done in American Apples at easier prices, as follows:—Wealthy, 15s. per case; McIntosh Red, 16s. to 18s.; Jonathan, 14s. to 17s.; and Grimes' Golden and David, 13s. to 14s. On the other hand barrels of Wealthy advanced sharply to 30s. to 40s.; while King of the Pippins at 30s. to 33s., and Gravenstein at 25s. to 26s., were steady. Doyenné du Comice Pears averaged 15s. per half-case and 27s. per case; Beurré Hardy, 13s. 6d. per half-case; and Winter Nelis, 26s. per case. Damsons realised 4d. to 5d. per lb.; Blackberries, 5d.; Plums, 2d. to 3d.; English cooking Apples, 11s. to 12s. per half-barrel; Gros Colmar Grapes 3s. 6d. per lb.; Alicante, 2s. 6d.; Black Hamburgh, 2s.; and Dates, 10s. to 11s. per dozen cartons.

Tomatos varied very much in quality, and while the produce from some growers sold at 6d. to 8d., selected fruits made 11d. Guernsey Beans were quoted at 1s. per lb.; field Mushrooms, 1s. to 1s. 6d.; cultivated, 3s.; Cauliflowers, 4s. to 7s. per dozen; Cucumbers, 6s. to 7s.; Lettuces, 2s. to 2s. 6d. per box; Leeks, 7d. per bundle; and Brussels Sprouts, 5s. per 20 lbs.

GARDENING APPOINTMENTS.

Mr. Allan Falconer, for the past seven years gardener at the Cheadle Royal Mental Hospital, Cheadle, Cheshire, as Parks Superintendent to the Stamford Park (Joint) Committee, Ashton-under-Lyne and Stalybridge Corporations. [Thanks for 2/- for R.G.O.F. Box.—Eds.].

Mr. Edwin Mason, for the past seven years deputy-gardener at the Cheadle Royal Mental Hospital, Cheadle, Cheshire, as gardener at the same place, in succession to Mr. A. Falconer. [Thanks for 2/- for R.G.O.F. Box.—Eds.]

NEW HORTICULTURAL INVENTIONS.

These particulars of New Patents, of interest to readers, have been selected from the Official *Journal of Patents*, and are published by permission of the Controller of H.M. Stationery Office.

Latest Patent Applications.

Printed copies of the full Published Specifications may be obtained from the Patent Office, 25, Southampton Buildings, London, W.C.2, at the uniform price of 1s. each.

Abstract Published.

A new hoe recently patented by Keep Macpherson, Ltd., of 252, George Street, Sydney, Australia, under No. 317,779, has the advantage that once the handle is fixed there is no possibility of the twisting round when in use, no matter how hard the tool may be used or how hard the ground may be. The haft socket of a hoe is made with arcuate end walls, and with parallel straight side walls. The curved shoulders of the blade are integral with the socket and encroach upon it for approximately half its length. All the walls of the socket taper from the bottom to the top, and the upper and lower faces of the socket are set at different angles to the blade. In modifications the shoulders may be straight, and the orifice of the socket may be rectangular.

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 47·0°.

Actual Temperature—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, October 30, 10 a.m. (Greenwich time). Bar. 29·9. Temp. 52°. Weather, Overcast.

Plant Life and Length of Day.

To what extent the length of a man's days is determined by hazard, heredity or environment has often been the subject of conjecture, but never of exact estimation. But we are further advanced with respect to our knowledge of plants, and are already in a position to show that the length of life of a plant is quite distinctly influenced by environmental factors; and that not merely by the obvious ones such as excessive heat and cold, drought and moisture, light and darkness, but by much more subtle ones as well. For example, as was shown some ten years ago by W. W. Garner and H. A. Allard, the length of a plant's days may be precisely determined by the length of the days in which its lot is cast. Be the day long, like Macbeth, some plants " begin to weary of the sun " and fail to come to floraison. Be the day short, there are plants which fail to get up sufficient speed of development to flower at all. Mr. Tincker, Keeper of the Laboratory at Wisley, who has already carried out numerous investigations on this subject—the influence of the length of day on flowering—has recently given us a further instalment[*] of his interesting researches. The account which he writes is, like the phenomena which he describes, somewhat involved, but the patient who will read it with care and attention will derive therefrom much valuable knowledge, and yet more food for creative thought. In proof of the statement already made that length of day may determine the length of the days of a plant, we may cite Mr. Tincker's observations on one of his " long day " plants, Phacelia campanularia. Seedlings sown in March and allowed to receive all the light they could get, got on nicely with the business of living and flowered and died in due course; whereas sister plants raised at the same time, but exposed only to a shortened day of twelve hours, were in no hurry to grow up, and were still in the vegetative stage three months after the plants which had suffered no curtailment of daylight had ripened their seeds and died. Nemophila insignis and Nigella damascena behaved in a similar manner. The last-named, sown in March and subjected to different light treatment in April, when they enjoyed the long days of later spring, elongated their flower stems in June and flowered in July, while others which were allowed only a twelve hours light pittance were still in the rosette stage when July came. On the other hand, Cosmos bipinnatus is a short day plant—as are ours, so are its days, " few and short." Give it long hours of daylight—and our hours of daylight in early summer reach so many as sixteen or even more—the Cosmos flowers but poorly, whereas, if its daily ration is one of twelve hours only, it flowers freely. Chrysanthemums are apparently also short day plants, daily light periods of twelve or even six hours accelerate flower production, whereas plants which receive the normal daylight of long summer days, although they grow taller, flower two months later. Plant physiologists are busily engaged in endeavouring to analyse this phenomenon, and have already made some progress; but much remains to be done before we can claim to understand these strange relations between length of day and plant development. Solomon who, as we know, was interested in plants, might have added to his list of puzzles which included the way of a ship in the sea . . . the way of a plant with the sun!

New Pavilion for Regent's Park.—Following the recent public appeal by Mr. George Lansbury, First Commissioner of Works, Mr. Louis Baron has promised to pay the cost of constructing a pavilion in Regent's Park as a memorial to his father, Mr. Bernhard Baron. The architects of the Office of Works are preparing plans to submit to Mr. Baron, and the pavilion will be for the use of boys and girls and others playing football, cricket, net-ball and other games in the park.

National Rose Society's Trial Ground.—A further extension has now been made to the National Rose Society's Trial Ground at Haywards Heath, and the raisers of new Roses are cordially invited to send plants of their new productions for trial in 1930. A minimum number of six plants of a dwarf variety, or two plants of a climbing or rambling variety, should be sent. Last year many raisers sent twelve plants of each new dwarf variety submitted, so as to give a fairer average trial. Raisers are assured that every attention possible will be given to any new varieties of Roses they may send. New Roses for trial should be forwarded addressed to Mr. Courtney Page, National Rose Society, Haywards Heath, Southern Railway, Sussex.

Timber Resources of the British Empire..—Mr. Fraser Story, in a contribution to *Svenska Skogsvärdsforeningens Tidskrift* (Stockholm, 1929, a 27, Vol. I, p. 85) on " Timber Supplies of the British Empire, with Special Reference to Softwoods," estimates the annual consumption of Coniferous timber in the British Empire at fifty-four millions c.m., of which Great Britain consumes 26·4 per cent., Canada 21·3, Australia 2·5, New Zealand, 1·6, South Africa 0·9, and the rest of the Empire 1·8. The home consumption of Canada is 21·3 millions c.m. and 33 millions are exported, eighty-six per cent. of this going to the United States. Canada's Coniferous resources are estimated at 5,000 millions c.m., but of this only 2,830 millions are accessible, The United States exports four times as much Coniferous timber annually as the growth; in Sweden, Finland and the Baltic countries a growth equal to exploitation is relied upon. The net annual growth of Coniferous timber in exploitable areas is only about forty-five millions c.m., while the exploitation is ninety-six millions. Mr. Fraser Story regards the recent estimate of accessible Coniferous timber in Siberia at 2,800 millions c.m. to be exaggerated. Accessible resources of Coniferous timber in other parts of the world are estimated to cover an area of forty-five million ha. The author considers that since the annual world consumption of Coniferous timber is 727 millions c.m. and the world's total of Coniferous standing timber is 27,875 million c.m., if the rate of exploitation is continued, there will be very little virgin forest left at the end of forty years. Hardwood resources in the British Empire (under reserve), are estimated by the author at about 6,000 millions c.m. He considers the shortage of hardwoods will be less acute owing to the natural reproduction of broad-leaved trees, and because they are less ravaged by fires.

Saving the Malvern Hills from Disfigurement.—We learn that a local committee has been formed to raise the required sum of money to purchase the remaining quarry rights on the Malvern Hills, so that the further disfigurement of the hills may be guarded against.

British Gladiolus Society.—This Society will hold its exhibition next year at Taunton, on August 13 and 14.

Preservation of Rural Surrey.—The institution of the Dorking and Leith Hill District Preservation Society took place on the evening of October 22. There was a crowded meeting, presided over by Sir William Lawrence, Bart., while Lord Crawford and Balcarres, President of the Council for the Preservation of Rural England, to which it is the intention of the Dorking Society to become affiliated, was present. Sir William Lawrence spoke of the work that had already been done in keeping the Dorking area unspoiled. Among other features, Box Hill had been purchased for the nation by Mr. Leopold Solomons; Glory Woods had been presented to Dorking by the Duke of Newcastle; a great number of the magnificent Spanish Chestnut trees in Betchworth Park, threatened by the new arterial road between Reigate and Dorking, had been saved; Bookham Common had been acquired and the trees in it preserved; and, finally, through the efforts chiefly of Mr. and Mrs. Roland Vaughan Williams, Friday Street had been saved for the nation. On Sir William's suggestion, a telegram expressing the gratitude and appreciation of the meeting was sent to Mr. Vaughan Williams.

The Tete d'Or Park, Lyons.—Probably most visitors to the city of Lyons, in France, have seen the beautiful park known as the Tète d'Or, which covers a space of 117 hectares. The citizens of Lyons are justly proud of the park, which, however, will have cost in upkeep in 1929 alone the large sum of nearly two million francs.

Legacies to Gardeners.—Colonel Sir J. A. Anstice, K.C.B., of The Old Grange, Dymock, Gloucester, who died on August 1, 1929, left £50 to his gardener, Mr. Joseph Trotter.—Mr. John Leigh, J.P., of Westleigh, Lea, Preston, left £250 to his gardener, Mr. James Ireland, if still in his service, and not under notice either given or received.

Kingston and Surbiton Gardeners' Society's Lectures.—The series of evening lectures for the coming winter session, organised by the Kingston and Surbiton Chrysanthemum and Gardeners' Improvement Society, and to be held on the first Tuesday of each month, in St. Peter's Church Hall, Norbiton, will commence on November 5, when Mr. W. Chandler will lecture on " Sweet Peas." Succeeding lectures will be on December 3, "Chrysanthemums," by Mr. H. Weaver; January 7, 1930, "Pruning Fruit Trees," by Mr. P. E. Cross; February 4, "Annuals" (to be arranged); March 4, "Bees," by Mr. C. H. Rose; April 1, a Special Talk, by Mr. W. H. Divers, V.M.H.; and May 6, a lantern lecture on "Our Local Birds," by Mr. D. A. Rawlence. The meetings will commence promptly at 8 p.m., and ladies and visitors are invited to attend the lectures.

---

[*] *Journal* of the Roy. Hort. Soc., Part 2, Vol. LIV

Heavy Crop of Potato Arran Banner.—On opening a "road" for the digger to raise a crop of Arran Banner Potato on the farm of Mr. William Gardner, Roddinglaw, Gogar, near Edinburgh, extending to ninety-seven-and-a-half yards long by six yards wide, the produce amounted to two tons seven hundredweights, a yield that works out at the rate of nineteen tons eight hundredweights per acre.

Floral Art in Brussels.—A successful and well-attended exhibition of floral art was held in Brussels, at the Palais du Midi, from October 12 to 14. The centre of the hall was occupied by a superb display by the Belgian Florists' Union and the firm of Bogaerts. The entrance of the hall was marked by an imposing collection of Palms and Ferns sent by M. M. Maricq et fils, including a specimen of the very rare Angiopteris fraxinifolia; at the other end of the salon was a group of fine Palms displayed by Messrs. Goossens. The right wing was occupied by a big display of Chrysanthemums from the well-known amateur, M. Odon Warland, and by various groups of Dracaenas, Chrysanthemums and Dahlias, while the left wing comprised Nephrolepis, Begonias and Cyclamens, and a fine display of Dahlias from the firm of Nagels, of Wilrijk. Along the walls were excellent collections of various kinds of fruits, and among others, exhibits from the Vilvorde Horticultural College, while at the bottom of the hall, in front of Messrs. Goossens' group of Palms, were the Orchids, notably a most attractive collection of Cattleyas and Cypripediums from M. Firmin Lambeau, and mixed groups from Messrs. Flandria, of Bruges; Messrs. Sanders, also of Bruges; and Messrs. Stuart Low and Co., of Enfield, Middlesex.

Horticulture in Roumania.—The Roumanian Horticultural Society is holding this year its usual autumn exhibition, from November 7 to 11, in the Carol Park in Bucarest. It will be opened by Queen Marie and the Royal Family, supported by members of the Ministry and the Diplomatic Corps, and there will be a number of exhibits from the Ministry of Agriculture, probably including produce from Army gardens. A large pavilion is to be erected, and also a cinema hall, where films of horticultural interest will be exhibited. The Society is making excellent progress, and at its usual meeting on September 21, was able to show a balance sheet with a handsome credit balance. For the eighth year in succession, Monsieur C. Faraudo has been elected President of the organising committee.

The Hop Crop in England and Wales, 1929.—In a preliminary statement by the Ministry of Agriculture and Fisheries, showing the estimated total production of Hops in the years 1929 and 1928, it is stated the Hop crop of 1929, produced under very favourable conditions, and on a slightly increased acreage, as compared with the previous year, gave a yield per acre well above the average. The quality of the crop was generally reported to be excellent. The total production in England is estimated at 359,100 cwts., or 117,000 cwts. more than in 1928, and 74,000 cwts. above the average for the ten years 1919-28. Over the whole of the Hop-growing areas the average yield per acre is estimated at 15 cwts., compared with an average of 10·2 cwts. in 1928, and 11·9 cwts. for the previous ten years. An improvement in the yield per acre was noticeable in all Hop-growing districts, the greatest increase being in Sussex, where the average yield per acre for the county was 16·8 cwts., compared with 10·1 cwts. in 1928. Hampshire, with 16·7 cwts. per acre, showed relatively less improvement, the yield for this county in 1928 being 12·7 cwts. per acre. These two counties showed a higher yield per acre than any other Hop-growing district except that of Kent, where the yield was 17·2 cwts. per acre. Hereford and Worcester, with 12·9 cwts., and 11·2 cwts. per acre, respectively, were 4·7 cwts. and 4·1 cwts. per acre higher than in the previous year. Surrey, with 12 cwts. per acre, returned only half-a-hundredweight more per acre than in 1928. About sixty-five per cent. of the total crop was grown in Kent, where the total production for the county was 233,000 cwts., compared with 162,000 cwts. in 1928. The yield per acre for the whole county was 15·7 cwts., or 4·8 cwts. per acre more than in 1928, and nearly 3 cwts. above the average for the previous ten years. The improvement in the yield per acre was most marked in the Weald, which gave 5·2 cwts. per acre more than in the previous year, while in the east and mid-Kent districts the yield per acre was about 4·5 cwts. higher than in 1928.

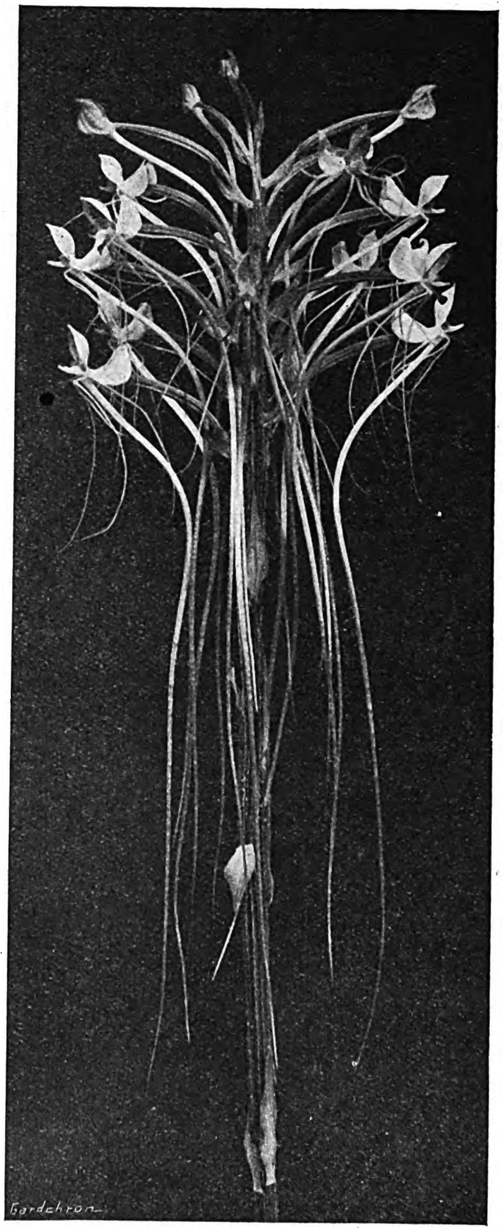

FIG. 156.—HABENARIA LUGARDII.

R.H.S. Award of Merit, October 23. Flowers white and green. Shown by Messrs. Sanders.

(see p. 333.)

A Bean-harvesting Machine.—For the third year in succession, trials have been carried on at Marolles-en-Hurepoix, Seine-et-Oise, in France, of machines for the harvesting of Haricot Beans, which are so largely grown in that country. Up to the present, no satisfactory machine has been devised, but this year the apparatus invented by a Paris constructor, M. Loiseau, gave excellent promise of success after one or two improvements have been made. Briefly the Beans are first cut near the ground by a sharp knife, or plough-share, and the plant is then gripped by two bands of rubber, which throw it to one side, at a distance which can be easily regulated, so that if desired the plants from several rows can be thrown on to the same heap. Or, if preferred, an arrangement similar to a reaper-binder, such as is used in a hayfield, can be brought into play, by which the plants can be tied together into bundles of the desired size. The machine, although solidly constructed, is light in weight and travels easily. The inventor has it in mind to construct a machine which will reap two rows at once, and is confident of being able, eventually, to supply machines which will give complete satisfaction.

Amalgamation of two Belgian Firms.—Those among our readers who have visited the fine horticultural establishments of Flandria, Ltd., at Bruges, in Belgium, and of M. Théodore Pauwels, at Meirelbeke, near Ghent, will be interested to learn that these two eminently successful businesses are amalgamating, and M. Pauwels is becoming an administrator of the Flandria firm, while maintaining his especial interest in the Orchid-growing department of the enlarged establishment. It is understood that the arrangement will be welcomed by the customers of the two firms, and by the world of Belgian horticulture generally. The head office will continue to be at Bruges.

A Gigantic Apple.—We are told that only half the normal supplies of Apples will be forthcoming this season owing to the failure of the Canadian and American crops, but should the Scottish crop approach anything like the specimens grown by Mr. J. H. Gait, Queen's Road, Stonehaven, Kincardineshire, Scotland, should suffer little from the shortage. Mr. Gait has just gathered his crop, and one of his specimens of Apple Mère de Ménage turns the scale at nineteen-and-a-half ounces, and measures fourteen-and-three-sixteenth inches in circumference. The excellent crop is attributed to the remarkably fine weather experienced during the past six weeks.

British Bulbs for British Parks.—The success which has attended the planting of home-grown Tulips in the London Parks during the past two years has led to further orders being placed among home-growers for the display in the spring of 1930. The cost of the bulbs—including home-grown Gladioli corms for a summer display next season—is being borne equally by the Office of Works and the Empire Marketing Board. It is stated that the principal London display of spring flowers in 1930 will be in St. James's Park. To further interest the general public in British bulbs, the Empire Marketing Board is arranging for an exhibition next year in the public parks of Cardiff. A large consignment of Bermuda Lilies (L. Harrisii) has already been received at Hyde Park.

Allotments in England and Wales.—Speaking at the tenth Annual Meeting of the Yorkshire County Allotments Federation, at Huddersfield, Mr. N. Buxton, Minister of Agriculture and Fisheries, stated that the allotment movement was deserving of every encouragement by individuals, by local authorities, and by the State. Whereas before the war only one-quarter of the area of allotments provided by public authorities was in urban districts, now the proportion is over one-half. In actual numbers urban allotment holders outnumbered the rural by over two to one. This interest of town dwellers in allotment cultivation was one aspect of the revolt against those features of nineteenth century industrialism which caused such misery to the workers. It was true, he continued, that some 300,000 allotments had disappeared since the war owing to the withdrawal for building and other purposes of large areas of land pressed into use for food production during the national emergency, but a comparison with the pre-war position showed a great advance. The total amount of land owned and leased by local authorities in 1928 was 57,021 acres, as compared with 33,523 acres in 1914, an increase of 23,498 acres. There was, however, still a large unsatisfied demand and Mr. Buxton appealed to local authorities to call allotment committees together at regular intervals and to see that all matters concerning allotments were referred to and discussed by them; he also reminded them that under the Act of 1925 they were given the power to spend up to a 1d. rate on allotments, and he could imagine no more worthy subject for expenditure if it were necessary in order to provide adequate facilities. Referring to the position of the allotment movement in Yorkshire, Mr. Buxton stated that one-ninth of all the allotments in England and Wales were situated in the three Ridings of Yorkshire, and of these five-sixths were in urban areas. In conclusion, Mr. Buxton expressed his pleasure with the prospect in the near future of the two organisations which at present represented allotment holders in England and Wales, viz., the National Union of Allotment Holders and the Allotments Organisation Society, coming together to form one National Society.

Gift of Italian Garden to Eton.—The Italian Garden which is now being constructed in the grounds of Eton College, near the Provost's Lodge and opposite College Field, is the gift of the King of Siam, who is an Old Etonian.

Chrysanthemum Madame Gabrielle Thiaux (Red Cavell).—We understand that a red sport from Chrysanthemum Edith Cavell appeared some time ago, and was exhibited on November 26, 1925, by M. Thiaux at a meeting of the Société Nationale d'Horticulture de France under the name of Madame Gabrielle Thiaux. We had verbal confirmation of this in Brussels a few days ago, and Mr. Simmonds, the Assistant Secretary of the Royal Horticultural Society—who first drew our attention to this matter of nomenclature—states that the red sport from Edith Cavell received a Certificate of Merit in Paris in 1925. It appears, therefore, that the name of Red Cavell (see p. 352) must be dropped in favour of Madame Gabrielle Thiaux, in accordance with the general principle of priority.

Friday Street Purchased for the Nation.—The efforts to secure the Severells Estate, near Friday Street, for the nation, have met with success, for on October 16, Mr. R. E. L. Vaughan Williams, K.C., who has been chiefly instrumental in raising the required purchase money, sent a definite acceptance of Sir Frederick Richmond's offer to sell the estate to the Friday Street Preservation Fund for the sum of £8,500, although the full amount of the purchase price had not then been subscribed. The sum of £250 had still to be raised, but this comparatively small deficit has since been wiped out, but the Fund is still open as it is hoped that enough money will be subscribed to make it unnecessary to call up the guarantees, amounting to £600, and also to have enough left in hand to carry out any work which may be necessary on the estate before handing it over to the National Trust. The question of the use to which the estate should be put has not yet been decided, but when the matter has been carefully considered by the organisers of the Fund, a statement will be issued; the chief question is whether the public shall have access to the place or not. Great praise is due to Mr. and Mrs. Vaughan Williams, and other organisers of the Fund, for the success which has crowned their efforts.

Roses at the Colchester Oyster Feast.—While enjoying the oysters provided for them at the world-famed Colchester Oyster Feast, the guests were charmed by the floral decorations of Carnations and Gladioli contributed respectively by members of the National Carnation and Picotee Society and the British Gladiolus Society. In addition, there was a fine display of Colchester Roses contributed by local growers who arranged, in the Mayor's Parlour, the numerous trophies and cups they have won this season. The flowers were arranged by (among others) Mrs. A. Prior and Mrs. Cecil Cant, and the guests included Mr. Andrew Ireland, Captain C. Harvey Cant, Mr. W. D. Prior, and Mr. A. E. Amos.

Appointments for the Ensuing Week.—Monday, November 4: Birmingham and Midland Counties Gardeners' Association's lecture. Tuesday, November 5: Royal Horticultural Society's Committees meet; Royal Caledonian Society's meeting; West of England Chrysanthemum Society's Exhibition (three days); Marlow and District Chrysanthemum Society's Exhibition. Wednesday, November 6: Lincolnshire Gardeners' Association's Exhibition (two days); Taunton and District Chrysanthemum and Fruit Society's Exhibition (two days); Royal Oxfordshire Horticultural Society's Exhibition (two days); Faversham Chrysanthemum Society's Exhibition (two days); Bideford and District Horticultural Society's Exhibition; National Carnation and Picotee Society's meeting; Wimbledon Gardeners' Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Kingston and Surbiton Chrysanthemum Society's Exhibition; Gainsborough Allotment Holders' Association's meeting. Thursday, November 7: National Chrysanthemum Society's Show (two days); Derbyshire Horticultural Association's Chrysanthemum Show (three days); Jersey Gardeners' Society's Chrysanthemum Show; Bridport Chrysanthemum Society's Exhibition; Newport Horticultural Society's Chrysanthemum Show. Friday, November 8: Cosham and District Horticultural Society's meeting; Chorley Chrysanthemum Society's Show (two days); Royal Horticultural and Arboricultural Society of Ireland's meeting; Leicester Chrysanthemum and Fruit Society's Exhibition (two days); Bletchley and District Horticultural Society's Autumn Show (two days). Saturday, November 9: Gloucestershire Root, Fruit and Grain Society's Exhibition; Leigh-on-Sea Horticultural Society's Chrysanthemum Show; Leeds Paxton Society's lecture.

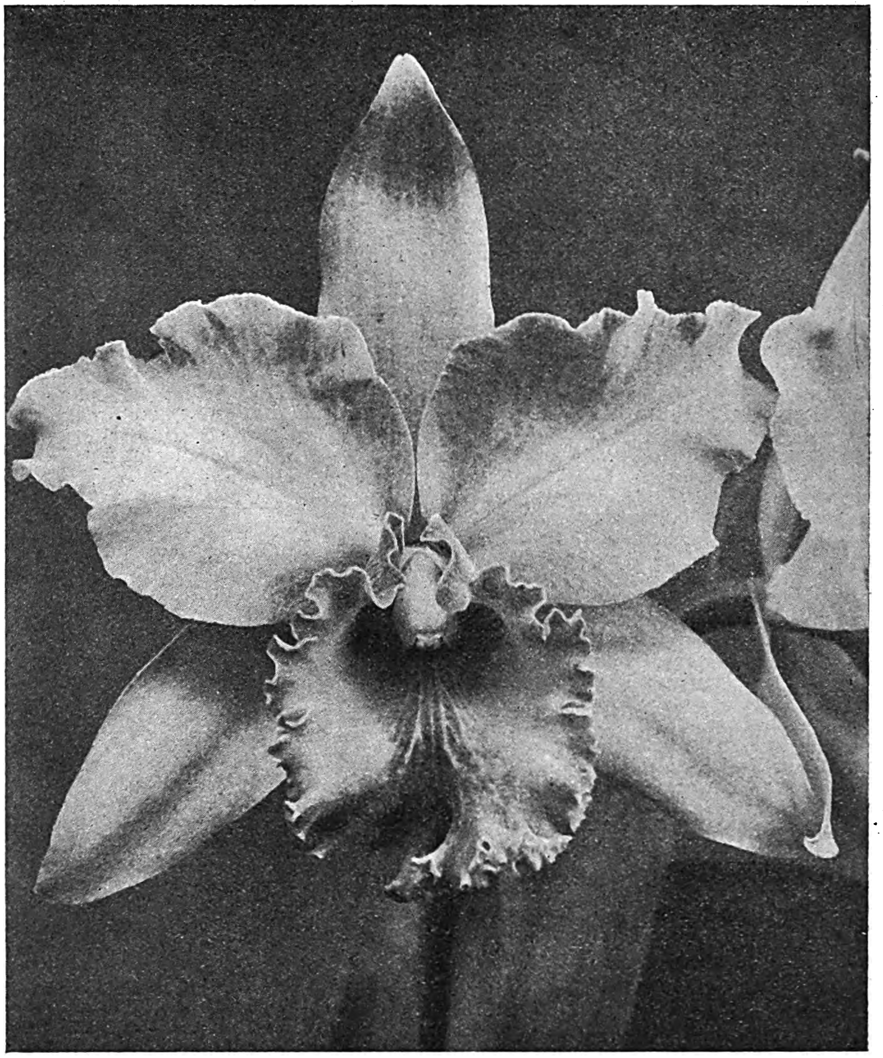

FIG. 157.—BRASSO-LAELIO-CATTLEYA AMBAUREA.

R.H.S. First Class Certificate, October 23. Rich yellow and cerise. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

(see p. 333.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Rheumatism.*—Gardeners, being very subject to heats and colds, often suffer much from rheumatism. Having been much affected with it myself, I wish to give them the benefit of my experience. Take one raw egg well beaten, half-a-pint of vinegar, one ounce of spirits of turpentine, a quarter-of-an-ounce of spirits of wine, and half-an-ounce of camphor, put them in a wine-bottle, and shake them well for ten minutes. In half-an-hour the mixture will be fit for use, when it should be well rubbed on the parts affected three or four times a day. In several instances this has effected a cure in a few days; but essence of mustard is best for bad cases. This is good for all outward applications in man or beast, green wounds, sprains, bruises, broken-kneed horses, saddle galls and bit galls. No farmer should be without it. *John Hayes, Farnham. Gard. Chron., November 4, 1854.*

Publications Received.—*A Countryman's Day Book: An Anthology of Countryside Lore.* Compiled and arranged by C. N. French; pp. xxvi 254. Messrs. J. M. Dent and Sons, Ltd., Aldine House, Bedford Street, W.C.2. Price 6s. net.—*Termites in Buildings.* Leaflet No. 31 of the United States Department of Agriculture, Washington, D.C. (no price).

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Seedling Dendrobiums.—Many of the larger plants will have formed pseudo-bulbs, and should be kept in a warm house in surroundings just moist enough to keep the roots active. Growth will not be very pronounced before the turn of the year, when, with the increasing light and sunshine, roots and new growth will be produced, and the necessary repotting may be done successfully.

Seedling Odontoglossums and Allied Subjects.—These require attention at various times. Larger plants, that are filling their pots with roots, should be repotted before they become pot-bound; healthy plants should be given slightly larger pots, without greatly disturbing the ball except to remove the crocks and any sour material. Use well-drained pots and a compost consisting of equal parts of A.1. and Osmunda fibres, and Sphagnum-moss, with a few broken, dried Oak or Beech leaves added; the whole should be chopped fairly fine and pressed firmly about the roots. A little extra Sphagnum-moss may be used with advantage on the surface. Smaller plants in the seed-beds, that are just developing their second leaf, may be pricked out into store-pots that have been filled and watered some hours previously. Keep the store pots in a moist position, well up to the glass, where the plants may be shaded from bright sunshine. These will grow well in an even temperature of about 60°. Spray the plants lightly on favourable occasions. Watering should be done very carefully when the compost is approaching dryness, to avoid disturbing the seedlings, and insect pests should be kept in check.

Temperatures.—At this season houses should be kept a little on the warm side at night, with sufficient bottom ventilation during suitable weather to prevent any stuffiness, although care is needed to prevent the pipes getting too hot, and thereby causing a very dry atmosphere in which insect pests, such as thrips, scale and red spider thrive. The temperature of the warm or East Indian house should range from 65° to 68°; the warm intermediate house, 60° to 65°; cool intermediate, 58° to 62°; and cool house, 52° to 58°. The lowest temperatures should be reached in the early morning. So soon as the canvas blinds can be dispensed with they should be dried and stored for the winter. The lath roller type of blinds may be used with advantage on cold nights as extra protection.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—Owing to the prolonged drought it has been an easy matter to keep the plantations free from weeds this season. Since rain has fallen, however, hosts of small surface weeds have germinated, and these should be got rid of before the soil becomes too wet. The soil between the rows should be lightly turned over with the fork, burying all the seedling weeds in the process. Endeavour to get the soil well up under the foliage of the plants so as to encourage and protect the surface roots. Established plantations of Strawberries have had a very rough time this year. The severe weather experienced last spring was in some degree responsible for many failures, and the plants were lifted by the frost and left high and dry for many weeks during a very critical period. Then followed one of the longest droughts on record, the effect of which is reflected in the very poor condition of the plants at the present time. New plantations, too, are none too happy this autumn owing chiefly to the extraordinarily dry conditions which prevailed since the runners were planted. I have urged, on one or two occasions, the desirability of planting Strawberry runners during the early days of August so that the plants may become well rooted and established before the winter. That precept I have endeavoured to carry out here, and, although we watered the plants individually for weeks after planting, they have failed to make that growth, or build up that crown which is desirable before the winter sets in. In the north of England and in Scotland some form of winter protection was, at one time, afforded the plants, such as a light dressing or mulching of half-rotted stable manure on the stiff retentive soils, and strawy farmyard manure for the lighter soils, which was afterwards forked into the soil during March or in April. Whether this is the practice now, or not, I am unable to state, but I see no reason why it should be discontinued, and it certainly would be advantageous, even in the south, should we experience severe frost such as we did early last spring. It appears to be a recognised practice on some of the Canadian Strawberry farms. The growers there admit that while the plants often come through the winter without protection, it is best not to take any risks. The system adopted is that, after frost has set in and the soil is quite hard, the plants are covered with a light coat of clean straw; two to three inches in depth is recommended, and straw that will not pack too closely over the plants is best. This mulch prevents the alternate thawing and freezing of the ground in the spring, and protects the plants if there is not much snow in winter. In early spring, when danger of severe frost is past and before the plants begin to grow, they are uncovered and the straw put between the rows to keep the fruits clean. The climatic conditions which prevail in this country and those of Canada are by no means similar, but there is room for experiment and trial for those who are inclined and can find the time.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Azaleas.—Azaleas are among the most useful plants for general decorative purposes in the conservatory during the winter and spring months. Large numbers of splendid, well-budded plants are imported annually, both of the indica and mollis varieties, and a very few plants will give a great quantity of bloom in return for the small outlay and labour entailed. Azaleas have very fine root-systems, and imported plants can be accommodated in rather small pots. A suitable growing medium is peat with silver sand added, and it should be in such condition that it may be made firm by ramming. After potting, the plants should be stood in frames from which frost can be excluded and sprayed occasionally; they should never be allowed to dry out at the roots but, on the other hand, they should not be saturated with water, or the leaves will soon drop, and the buds may not develop. After a few weeks of this treatment they may be moved into warmer quarters in sufficient quantities to meet the demand, and forced gradually into flower.

Spiraeas.—The many herbaceous Spiraeas (or Astilbes) are suitable for producing flowers in the early spring, and as they are now available in large quantities and great variety, some should be secured and potted forthwith. Among varieties suitable are S. palmata, S. Peach Blossom and S. Alexandra. These will be found extremely useful, and when a batch is well-grown many spikes of flowers in varying hues give a delightful effect. Spiraeas delight in a somewhat heavy compost which should be made fairly firm, and when potting these plants it is well to place them so low as possible in the pots, so as to leave plenty of room for water, for when in growth they require an abundance of water at the roots and should on no account be allowed to become dry. When the flower spikes are developing it may be necessary to water them twice daily on bright days. A good plan is to stand the receptacles in saucers of water so that the roots always have a reserve of moisture to draw from.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Late Vineries.—The fruits of Alicante and similar varieties of Grapes should now be quite ripe and ready for use. Gros Colmar and Lady Downe's, the latter almost beaten out of the field by coarser and larger-fruited varieties, require a longer season, and those who still appreciate high quality give them Muscat treatment. The weather has been most favourable to the finishing of the fruits of these varieties, but the use of a little fire-heat must not be relaxed until the foliage, the true test of maturity, shows signs of changing. The borders should be examined, for although feeding is finished, it should not be overlooked that the berries must be kept fresh and plump until Christmas. Tepid water, at a temperature of 80°, may be given, and to prevent damp rising, the whole border should be well mulched with some dry material. Late Muscats now ripe and well-coloured may be subjected gradually to a lower temperature, with a proportionate reduction of atmospheric moisture. As Muscat Grapes are so subject to damping, the house should be kept quite dry when the outside atmosphere is moist and heavy. Other late varieties of white Grapes such as Mrs. Pearson, require plenty of time to mature, and when well finished should keep in good condition for some considerable period

Cucumbers.—Plants now in bearing may be afforded applications of weak warm liquid manure alternately with clear water, especially if the roots are confined to pots or narrow pits. They should also be top-dressed with light, rich turf, to which plenty of rough lime-rubble and a sprinkling of bone-meal have been added. Do not allow the foliage to touch the glass, and if space is plentiful, growth should not be checked too much by stopping. Very strong laterals, of course, may be pinched back to maintain a proper balance, while some of the laterals which have borne fruits may be cut away by degrees to make room for an even spread of foliage. As Cucumber fruits are not much in demand throughout November and December, the plants should not be overcropped, especially if they are expected to crop during January and February. Reduce the male blossoms, as these weaken the plants, and cut the fruits when three-parts grown. Direct syringing having been discontinued, atmospheric moisture and, at the same time, a brisk bottom heat of not less than 60°, should be maintained. Any late plants should be encouraged if intended for use early next year, by careful watering and feeding, especially if the root-run is limited.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens. Wisley, Surrey.

Replanting.—Those who contemplate alterations or improvements in the flower garden will find late October and early November the best time to carry out such operations. The ground then is comparatively warm and favourable for the production of new roots; therefore every endeavour should be made to carry out the planting so early in November as possible. The preparation of the ground is an important factor, and in all cases should be thorough, as the future success largely depends on how this has been done. Beds or borders that are to be planted with shrubs or ornamental trees should be trenched at least two feet deep and the subsoil broken up with a fork. Decomposed vegetable matter or old turf should be added, according to the nature of the soil. Plant immediately the plants are received, if weather conditions permit, rather than heel them in; make all the larger specimens secure with stakes where necessary.

Roses.—Where new beds of Roses are to be planted, one of the most important details is to plant them so early as possible; if planted during early November they should have formed many new roots before the end of the year, if the weather is at all open. The beds or borders for their reception should be prepared now, deep trenching, breaking up the subsoil, and incorporating a liberal supply of farmyard manure and bone-meal as the work proceeds, being essentials towards securing satisfactory and lasting results. When adding to the collections of Roses, liberal plantings of the dwarf Polyantha types may be made with advantage. In this section there are many varieties that are ideal subjects for massing, and are a real acquisition to the flower garden during summer.

Gladioli.—The corms of these should now be lifted, and stored in a dry, frost-proof shed. Keep the various sorts separate by tying them in bundles or placing them in boxes. They can be picked over during wet weather after they have been dried off.

Tigridias.—It is usual to lift the bulbs of these every autumn, except in the milder districts, but we found these wintered well last year, even although the thermometer registered below zero on three successive nights. The only protection they had was about four inches of dried Bracken, pegged down over them. The growth this season has been stronger than if the bulbs had been lifted and planted again in spring.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Rotation of Vegetable Crops.—This matter should now be considered, so that the ground for the various crops may receive appropriate treatment. Most vegetables enjoy a change of quarters, although it is well-known that Onions and Potatos, provided they receive good cultural treatment, may be grown on the same ground for several years in succession. Carrots, Beet and Parsnips should be grown in ground which was well prepared for the previous year's crops, as they like a mellow soil and strongly object to the presence of fresh manure; ground on which Celery has been grown should suit these crops admirably.

Vegetables.—Cauliflowers, Lettuces, Parsley, Carrots, etc., in frames, should be kept free from weeds and the surface soil stirred frequently. Water should be afforded in moderation. French Beans in cold frames require very careful airing and watering, as they are very liable to damp off. On cold nights, cover the frames with plenty of protective material.

Seakale.—So soon as the foliage has died down, sufficient crowns of Seakale may be lifted for forcing. Break the smaller thongs from the main root so that four or five may be placed in a nine-inch pot, or they may be planted out in a bed in the forcing house where a temperature of 50° to 60° may be maintained.

Celeriac.—This crop should now be lifted and stored in sand or ashes in a sheltered position.

Cauliflowers.—Where the heads of Cauliflowers are ready for cutting and are turning in too fast, the plants may be pulled and placed in a cool cellar or in deep, well-ventilated frames, and shaded with mats, under which conditions they should keep fresh for several weeks. Autumn Broccoli may be treated in the same way, as frost will soon spoil the heads when fully developed and if left unprotected.

Seed Potatos.—Tubers selected for seed sets, when well greened, should be placed in store boxes, provided they are perfectly dry. Discard any that have signs of disease, and see that each variety is labelled correctly.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Forcing Seakale and Rhubarb.—As the leaves fade on Seakale and Rhubarb, a few roots should be lifted and exposed to frost preparatory to planting them in heat for forcing. Rhubarb from which few sticks have been pulled during the past season should be selected for forcing, as only such can be expected to give a good return for the trouble involved. Any dark warm corner in a shed or cellar should prove suitable, provided sufficient moisture is afforded, but if such is not available, a low, wooden erection surrounded with fermenting material such as horse manure, leaves, or a mixture of these, makes a capital forcing chamber. If procurable, The Sutton is the best variety of Rhubarb, being of excellent colour and possessing a flavour all its own.

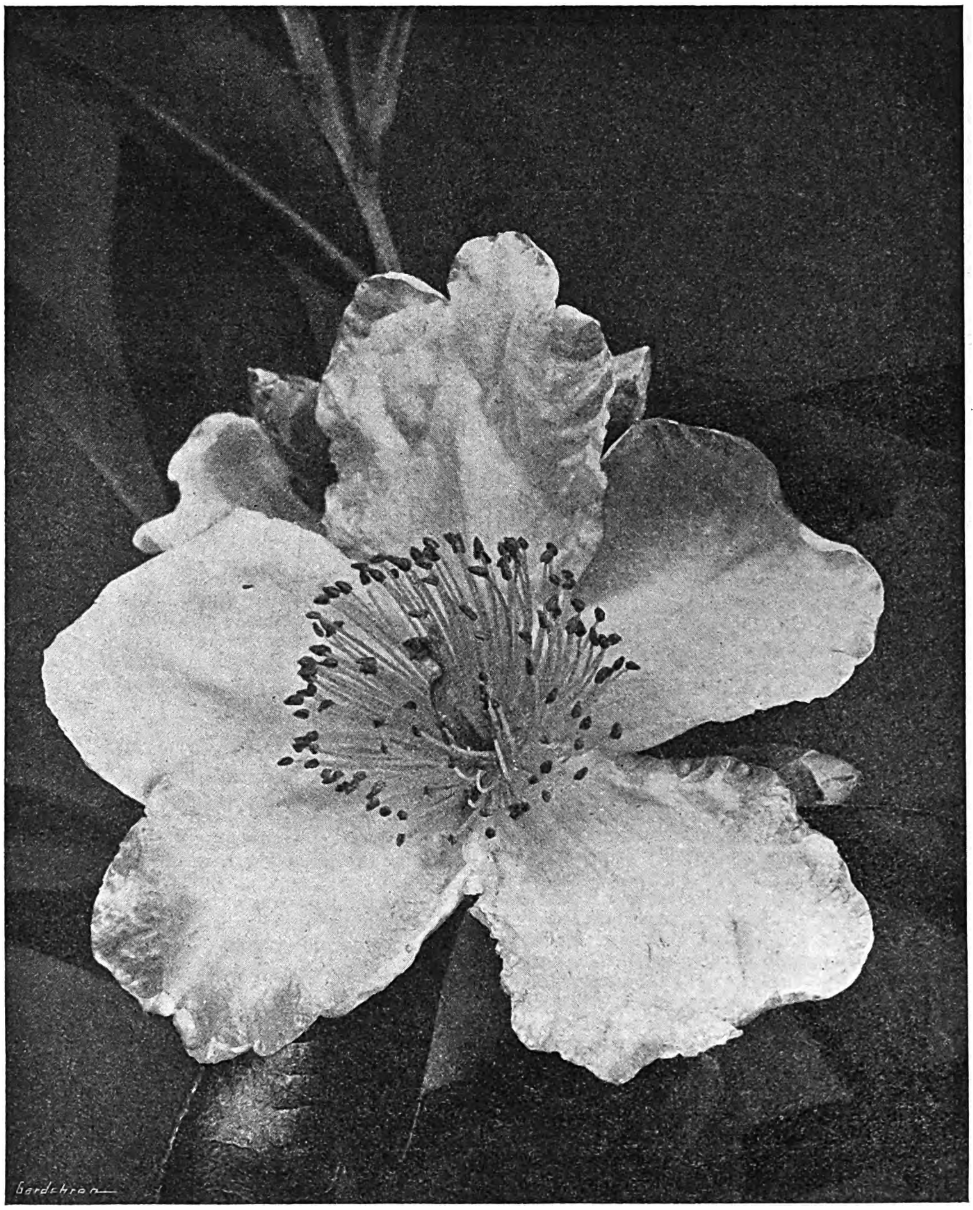

FIG. 158.—GORDONIA AXILLARIS.
R.H.S. Award of Merit, October 23. Flowers white, with golden stamens.
Shown by Major L. Johnston, Campden (see p. 334).

Planting Fruit Trees.—This work should be pushed on if the weather is dry, and the ground in workable condition. The ground for a new plantation of fruit trees should be deeply cultivated, but unless the under soil is of the finest quality, it should not be brought to the surface. If on grass, the turf should be buried just so deeply as to cause decay, but yet to be within easy reach of the roots in the immediate future. Unless poverty-striken, no manure should be incorporated with the soil, but a good mulch of fresh manure placed above the roots is of great benefit. When the soil has settled, planting may be done at any time. If of a light nature, holes should be opened at the necessary distance, deep enough to allow of the trees being planted to the ground mark on the stems, but if the soil is heavy, shallow planting should be practised; in extreme cases, setting the tree on the level and raising a mound round it, is advisable. Even for bush or pyramid trees a suitable stake should be provided and fixed before planting. The roots, after all bruised or broken parts have been trimmed off, should be spread out all round, and some of the best soil available worked in among them with the fingers; if fresh loam can be used for this purpose, so much the better. When this has been done, the filling in may be completed with the staple soil, and the whole trodden quite firm. Some system of naming the trees should be adopted, so that each variety may be identified easily. On the question of pruning newly-planted fruit trees, a good deal of controversy has taken place, but I strongly advocate cutting back the leaders and spurring back all side growths a few weeks after planting, as it helps to restore the balance between root and top. When planting fan-trained trees on walls it will generally be found that every tree, upon arrival, has a central growth pointing to the top of the wall. This, I consider, should be cut out at once, as it naturally gets the most direct flow of sap, and grows too strongly, at the expense of the side branches; I find that if the sap is directed to each side near the root a much better balanced tree results. In all cases the trees should be tied rather loosely at first, to allow them to settle with the soil. Permanent ties should be provided later, and some means taken to prevent frictional injury to the bark.

SALVIAS.

THE interesting note on certain economic Salvias in your issue of October 19 (p. 306) prompts me to send an account of some varieties with conspicuous flowers. This has been a successful year for Salvias and allied genera; the warm weather which followed the recent rain has made plants which were suffering somewhat from the drought produce a magnificent show of blossom. S. splendens may now be obtained in a variety of colours, including a yellowish-white, a streaked white and red, and shades of violet; it also may be had with yellow foliage, or with foliage spotted like the leaves of an Aucuba, but I think the only form worth growing is the bright scarlet one with which we are all so familiar, and of this, good varieties are Zurich, Vesuvius and, perhaps, best of all, Harbinger. Like most of the Salvias, it is very obliging, and may either be raised from seeds or from cuttings, or by lifting stools and potting them up in due course. It is very good both outside and as a pot plant, and for the latter purpose may be grown into a standard.

Another universal favourite is S. patens. This may be had in the dark blue form, in a white form, and in a very beautiful Cambridge-blue form, for which Mr. T. Hay recently received an R.H.S. Award of Merit.

One of the best Salvias for bedding-out is S. Pitterii, with bright scarlet, very hairy flowers; it is most floriferous, and at the time of writing I have a hedge of it in the garden fifty feet long, and composed of shrubs three feet high and four feet through. Another scarlet Salvia is S. Grahamii, which is somewhat similar but, in my experience, much less compact. The third scarlet Salvia, S. rutilans, has much smaller flowers but should be grown for the delightfully scented leaves which recall the fragrance of a Pineapple. This plant, like the other two scarlet Salvias, often comes through a winter safely.

A Salvia with large flowers of bright pink, freely produced, is S. Greggii. This, in the Isle of Wight and elsewhere, grows into a big bush, but it is, perhaps, most effective when plants raised from cuttings taken the previous autumn are bedded-out; it is in bloom all the year. There is also an unattractive yellowish-white form and another variety with deeper pink flowers.

A rank grower which, however, is very handsome in the herbaceous border is S. involucrata. This makes magnificent spikes some eighteen inches long on which, however, the bright pink flowers are set at rather too long intervals to be effective; the variety S. involucrata var. Bethellii has overcome this defect and the flowers are closely clustered together at the end of a much shorter spike, the bracts also being conspicuous. My favourite Salvia is the exquisite S. uliginosa, with tall spikes which sway in the wind; it is apt to die out in some localities and requires a rather stiff soil. It is easily propagated from cuttings taken in the autumn. Another very beautiful Salvia, with a rich blue lip, is S. Pitcheri (S. azurea var. grandiflora ?). This, however, although perfectly hardy, does not produce its flowers until October, and consequently is generally ruined by frost. This year it is excellent; it makes a very good pot plant. S. farinosa is a lovely plant which begins in August to produce spikes which exactly resemble those of a very noble Lavender. It is generally raised from seeds, but as the seedlings vary a good deal, is it best to select a good form and then keep up the stock from cuttings.

S. leucantha is a very pretty plant with white tomentose foliage, and spikes of violet flowers almost entirely covered with dense white hairs. It rarely comes safely through a winter outside, and should be considered a greenhouse plant. A Salvia re-introduced to cultivation is S. mexicana, a handsome and very strong-growing plant with deep purple stems and veins and hairy, indigo-blue flowers which are, however, produced somewhat sparsely.

When growing Salvias from seeds it is of the greatest importance to obtain a good strain and I strongly recommend growers to consult the results of the very successful trials of Salvias raised from seeds at Wisley.

Another very pretty, but rather tender, plant, is S. erubescens, with claret-coloured inflorescences. Salvia aurea has not yet flowered; it is an attractive plant with small, hard, sage-green leaves set closely on the stem, and is worth growing for its foliage alone, only it is not hardy.

Up to the present, we have not succeeded in flowering the Californian Sages known as Audibertias. They have, however, made very fine plants this hot year, and we have lifted them to see if they can be induced to flower under glass. *William Lawrence, Burford.*

ALPINE GARDEN.

SCABIOSA COLUMBARIA.

THE native plants of dwarf stature which are planted in our rock gardens are comparatively few, and yet there is a goodly number which might well be accorded such favour. Among these is Scabiosa Columbaria.

This species is not an uncommon wild plant in England, and is comparatively plentiful on the east coast, while its distribution extends throughout Europe. Although it cannot claim to rival the more popular and freely planted species of Scabious when grown on the rock garden, it repays such consideration generously and becomes quite a charming feature in a warm, sunny spot.

S. Columbaria forms a tuft of greyish, pinnate leaves, one foot or more across, often developing a woody stock with age, and produces its flowers in no niggardly fashion during the summer months and often well into the autumn. The flowers, typical of the genus in form, are comparatively small, being barely an inch across, but they are a delightful shade and are produced on either simple or branching, slender stems up to nine inches or so high. Although merely a native, S. Columbaria can hold its own with many plants from foreign climes which are grown extensively in rock gardens of the present day, and a word or two in its favour may not be amiss.

POLYGONUM CAPITATUM.

OPINIONS are very much divided as to the value of Polygonum capitatum for the rock garden. In the first place, it may only be safely regarded as half-hardy, a factor decidedly against it so far as the rock garden is concerned, while, although by no means unattractive, it has no special beauty to commend it, all of which tends to suggest its banishment as a plant unworthy of further consideration.

But, on the other hand, this Knot-weed from the Himalayas is an excellent carpeting plant, so far as habit of growth is concerned, and as there are always places in the rock garden, such as the beds containing early-flowering bulbs, which are better for a covering, if only temporarily, P. capitatum may well be employed for such a purpose. As it does not mind partial shade, and as this condition does not induce it to grow with such abandon as to be detrimental to neighbouring and, perhaps, choicer plants, it is obvious that this Polygonum is not to be despised. P. capitatum is sometimes listed under the possibly grander, but, nevertheless, incorrect name of P. sino-capitatum.

Briefly stated, its qualifications are that it forms a close, creeping mat of slender, reddish stems set with small, bronzy-green leaves, each of which is marked with a crimson A-shaped bar. In late summer, by which time it has developed into a broad, mottled mat, numerous small, rounded heads of pale pink flowers are produced. Although rather inclined to be dingy, these flowers are by no means worthless, being borne very profusely on short stems just clear of the foliage.

If considered worthy, steps may be taken with the approach of frosts to ensure its survival by potting up a few rooted portions and wintering them under cover; if regarded as unworthy, it may be left to take its chance. *Kent.*

SCABIOSA VESTINA.

THE alpine species of Scabious usually met with in rock gardens are Scabiosa Pterocephala (often grown under the name of Pterocephalus Parnassii), an invaluable rock-covering plant for a warm, sunny position, and the elegant and very beautiful S. graminifolia, whose praises have often been sung, for it is a plant of rare charm and refinement.

But there are other species of this popular genus worthy of the attention of the alpine plant lover, S. vestina being one of these. Although not quite equalling either of the above-mentioned in decorativeness, it yet does not fall far short of being a first-class rock garden plant, especially when it is borne in mind that it is summer-flowering and produces its charming blooms, never plentifully, but in succession from July onwards for many weeks.

S. vestina forms—if planted in a sunny position and light, but by no means poor, loamy soil—a mass of fine, feathery, grey foliage, from among which are produced the speading stems, barren of foliage, and about nine inches long, which bear the large, lavender-coloured flowers. These are nearly one-and-a-half inch across and have disc florets of a lighter shade.

This Scabious is not often met with in gardens, but is a plant well worth securing, for it is a good perennial and by no means difficult to establish and propagate. *M. W.*

SAXIFRAGA FORTUNEI.

THERE are comparatively few plants which consent to give us a display of blossom during these dull autumn months, so do we the more appreciate those which are in flower now—normally or abnormally.

Saxifraga Fortunei is just now at its best. I have it planted in a cool corner of rich soil facing north, and here, where its foot-high flower stems are protected by a sheltering wall behind, it seems perfectly happy. It belongs to the Diptera group and has short, sturdy rhizomes, from which the leaves and flower stems are produced; the leaves are glossy green, large and handsome, each scalloped into seven or more lobes. Uprising from among these are the reddish flower stems bearing quantities of the quaint flowers, the petals of which are clear white, the top ones serving as a dainty background for the vivid orange stamens which lie back against them. The quaintness of the flowers lies in the unevenness of the petals, the bottom one of the five being quite three times as long as any of the other four, and hanging straight down, giving the appearance of a pendent, lower lip.

It is a Chinese plant, and cannot be relied upon to appear in the same spot with unfailing regularity. It is given to dying-off during our winters, but is more or less permanent in well drained, rather rich soil and a cool, well protected corner, such as I have described. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

WOODLAND GARDEN.

LACTUCA BOURGAEI AND L. PLUMIERI.

THESE two species are, on account of their floral and foliage attractions, and also because they are not so rampant in spreading as to become troublesome, probably the most attractive and useful of the decorative Lactucas, a genus that has given us the Lettuce, but which also embraces a large number of worthless subjects.

As to whether Lactuca or Mulgedium is the correct name of the group to which the above two species belong, the authorities would appear to disagree so heartily that one can only justify the use of Lactuca as the generic name on the authority of *Index Kewensis*, although in the majority of works of reference Mulgedium appears to find favour.

L. Bourgaei and L. Plumieri, both hardy herbaceous perennials, are vigorous growers, producing ample and handsome foliage and giant inflorescences of starry, Aster-like flowers. They are, perhaps, better suited for the wild garden, or an open position in the woodland, than for the herbaceous border, unless the border is of considerable size. Both species are natives of southern Europe and both, under congenial conditions, attain a height of at least four feet, sometimes considerably more.

Of the two, L. Bourgaei is the more desirable as, although easy to establish, it does not take such complete possession of its quarters as L. Plumieri, which has a leaning towards coarseness and should, therefore, be planted in the wildest parts.

The large leaves of both species are very effective—nothing will grow beneath them—while during July and August they both produce, on stout and strong stems, their giant, feathery and spreading panicles of flowers which, although comparatively small individually, are produced so generously as to be very effective. Those of L. Bourgaei are of a charming shade of soft lavender-lilac, while those of L. Plumieri are, perhaps, best described as light steely-blue.

Other members of this group of plants are sometimes met in gardens, notably L. alpina, which, however, on account of its extreme fondness of cultivation, is best avoided—it has a reputation of being very difficult to part with after once having been introduced. Mr. E. A. Bowles, for instance, writes of this species (*My Garden in Summer*): "If ever you want to provide an unending struggle for a brother gardener, and perhaps make a lifelong enemy of him, give him a morsel of the Blue Sowthistle, Lactuca alpina." Incidentally, of L. Bourgaei, Mr. Bowles wrote that his oldest plant of it had "sat in the same place for fifteen years."

Farrer, in his *English Rock Garden*, wrote of them under Mulgedium, his fairly extensive list of species including both worthy and unworthy. A suggestion of Farrer's, worthy of note, is that they may be used as cover plants for Snowdrops and as "nurses" to the smaller Narcissi. *W.*

HARDY FLOWER BORDER.

MECONOPSIS VIOLACEA (K.W. 7,207).

WHEN pulling up a number of ripened, flowering stems from a colony of the recently introduced Meconopsis violacea, it occurred to the writer how little, if any, publicity had been given this deserving plant. It may be that exhibitors of new and rare plants are still loath to show a new species of this genus, feeling that, whatever it is, it must fall far short of Meconopsis Baileyi. However, the relative value, as garden plants, of these two Meconopses may best be considered by referring to M. violacea in the masculine, and M. Baileyi in the feminine gender; in the former we have a bold, sturdy plant, in the latter, grace, refinement, exquisite colouring, and all the beauties attributed to things feminine. Although the amount of collected seeds allocated to my employers was not in any way alarmingly large, the seeds germinated freely and the seedlings grew apace, from start to finish, with unabated vigour. The plants were set out in shade, in an open border and came through the winter without any protection. The great rosettes of silvery-grey leaves, when covered with hoar frost, were quite an attractive sight on a wintry day. Without any extravagant cultivation, many of the flowering spikes were but a few inches short of six feet tall, with thirty to forty large, violet-blue flowers studded with immense orange anthers. We in the Emerald Isle think highly of this noble Meconopsis, and predict for it a great future, and regard it as another plant to perpetuate the name of the intrepid explorer, Captain F. Kingdon Ward. *T. W. Bolas, Mount Stewart Gardens, Co. Down.*

TREES AND SHRUBS.

CORNUS KOUSA.

THIS interesting and attractive member of a family of plants noted for their decorative value in the garden, is in many respects one of the most intriguing of the larger-growing species. Fruiting branches were exhibited at the recent autumn show of the R.H.S., and they attracted a considerable amount of attention.

Forming a tree of deciduous habit and rarely growing above twenty feet high, this species is probably grown primarily for the flowers and secondarily for the fruits which follow. The leaves, borne on short stalks, are opposite, ovate and acute, with an entire but wavy margin, and from one-and-a-quarter inch to three inches long, and about half as wide. The leaf-surface is dark green and smooth, except for bunches of minute hairs at the junction of the veins.

The flowers, borne in May and June (and sometimes continuing into July), on spurs along the branches, are of no beauty in themselves, forming tight little masses, not more than half-an-inch across. Each little button is, however, surrounded by four lanceolate bracts, averaging an inch in length and half-an-inch in width. These bracts are cream in colour and are the distinctive feature of the plant when in bloom. Other garden species of Cornus, such as C. Nuttallii, C. florida and C. capitata, have these bracts, and all are valued on this account. C. Kousa is, indeed, a magnificent sight when in full bloom, with scores of creamy bracts staring straight up at the sun in their flat, four-pointed stars, and this year the species has flowered exceptionally well in the neighbourhood of London.

The flowers, which last for some considerable time before turning brown, withering, and falling from the tree, are followed by the handsome, Strawberry-like fruits, rich crimson in colour and about the size of a Barcelona Nut. This shrub will grow in any good loam, and it appreciates moist conditions, although it is not a subject for dense shade. It likes sun, but, as with most trees and shrubs, it does not relish drought. Although C. Kousa has been described as of bushy habit, it may, on occasion, be quite slender and almost columnar in growth, and sparsely branched. If such is the case, it is apt to be wind-blown in exposed situations. Although strong winds may blow the top over, it is fairly safe to assume that the more exposed the position, the more dwarf and bushy the growth. As a specimen small tree for wide lawns, C. Kousa is ideal.

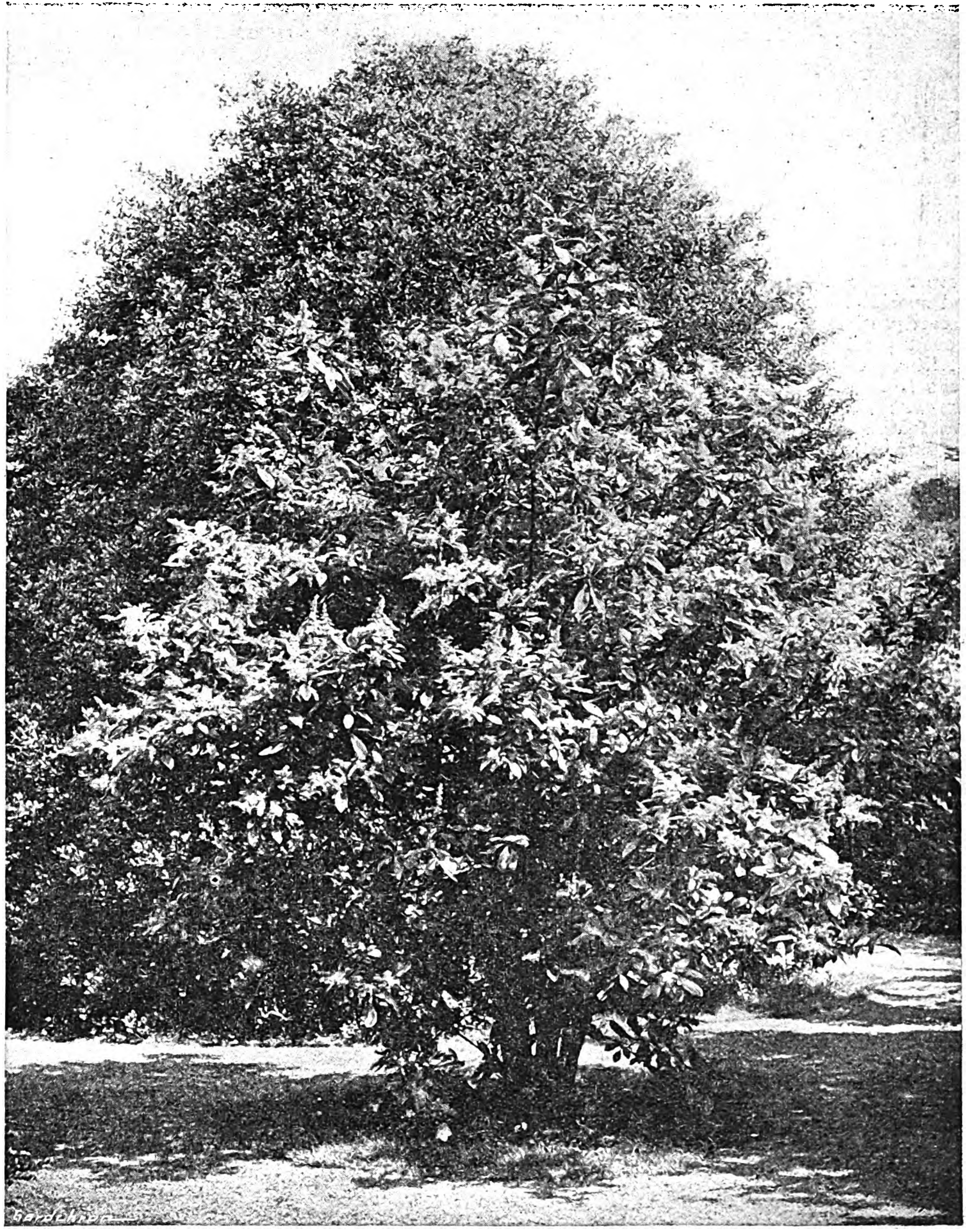

FIG. 159.—MELIOSMA CUNEIFOLIA.

(see p. 348).

Unlike C. florida and C. Nuttallii, which are natives of North America, C. Kousa comes from China, Japan and Korea, and considering its origin, the species is reasonably hardy in most localities in England. It is a close relative of C. capitata, which hails from the Himalayas and China, but the latter is not so hardy and has yellow bracts which are broader than those of C. Kousa. C. Kousa may be found under Siebold's name of Benthamia japonica and there is a variety, chinensis, which is considered to be superior to the type. *L. B. Creasey.*

THE N.R.S.'S SELECT LIST OF ROSES.

The new edition just to hand of the National Rose Society's *Select List of Roses and Instructions for Pruning* is on similar lines to the last one published five years ago. It is dated for the coming year (1930), and the Publication Committee shows consideration in issuing it this autumn, so that it may be of use to those who are selecting varieties to plant this winter.

The preface wisely states that the list of Roses is a "selection," and not a "catalogue"; and further adds that Rose growers of experience and special local knowledge should not lightly discard varieties not included but which have proved particularly satisfactory with them.

Although there are a goodly number of eliminations from the 1925 issue, the list has grown somewhat in length. The number of new varieties now forthcoming, thanks to an increase in the number of raisers and to the desire to exploit to the utmost the possibilities of the Pernetiana element, has no doubt forced some lengthening of the list. The number of varieties, leaving out the Rose species, now briefly described, total nearly four hundred.

In the alphabetical method of listing used there is one slight change noticeable. The "Madames" are entered according to the arrangement of the letters in the abbreviation "Mme." and not as formerly in that of the full word. Such placing is consonant with that of the English equivalent "Mrs."

It is interesting although, perhaps, at times a little heart-aching to old Rose growers to take note of the discarded varieties, for once a Rose disappears from this authoritative list the chance of its ever regaining a place is remote. However, of the eighty or so discards from the 1925 edition, the vast majority are fairly recent introductions which have not "caught on," either through some marked defect, such as feebleness of growth, or else have been rapidly superseded by similar but better varieties.

Of Roses introduced this century—a convenient dividing line—some of the most striking omissions, taking them in chronological order, are Mrs. Theodore Roosevelt, J. B. Clark, Mrs. E. G. Hill, G. C. Waud, Melody, Donald McDonald, Joanna Bridge and Mrs. Elisha J. Hicks. None of these have I grown, so, as far as my feelings are concerned, they go without a regret. I am, however, a little surprised to see such a decorative variety as Joanna Bridge disappear so soon. Then there is one further very marked omission among the Roses introduced this century, namely, the Lyon Rose—the sensation of one of the shows of the first decade. Moderate growth and its liability to black spot may have been its undoing; but against these should be put its superb bloom, which both lasts and keeps its colour well in a vase. In the interests of the history of the garden Rose surely Pernet Ducher's wonderful creation, which ushered in a new race and introduced new colouring into our bedding Roses, should not be allowed to go out of cultivation.

Of Roses which saw the light last century, I have only been able to find three discards. Bessie Brown at last goes. This weak exhibition Tea variety has fairly well, one imagines, outstayed its welcome. The Noisette climbers are one fewer through the leaving out of Alister Stella Gray. This is rather surprising, as it is most vigorous, with a long flowering period. It may lack distinction, but it has the saving grace of fragrance, and is a useful rambler for an odd corner. The dwindling Hybrid Perpetuals are reduced still more by the rejection of Captain Hayward. Ulrich Brunner is retained. Of the two, I should prefer the Captain Hayward, but then Ulrich Brunner may be more of a success in the way of fulness and richness of colouring in the cooler and damper north-west than in the south-east.

The old H.P.'s are now reduced to four—Ulrich Brunner, Mrs. John Laing and Victor Hugo, dating from the eighties, and Général Jacqueminot so far back as the year 1853. It comes in the list next to another General, of much more recent date, also highly scented—the popular General McArthur.

Of recent Roses one looks in vain for William Kordes—a Hybrid Tea of distinction. It was introduced in 1923 and was included in the leaflet of newer Roses issued by the Society between the last and this edition. It was there described as being of moderate growth and best as a maiden. Lack of vigour is probably responsible for its exclusion. It is under trial in my garden, and as I write in mid-October there is before my eyes a fine bloom cut from a fairly vigorous plant which is not a maiden. I especially like this variety for its colour, stiff stalk and its indifference to rain. Another Rose, somewhat similar in character and most likely left out for the same reason, is Marie Adelaide. It is worth struggling with for its stout stalk and other desirable qualities in its flower.

The "Pruning" part of the publication barely calls for comment, as there is little in the way of alteration and addition. The instructions are very complete, and even the pruning of the Perpetual Scotch Rose receives some consideration. It is interesting to learn that the unique single Rose, Mermaid, has withstood 38° of frost. There is a warning against the over-pruning of extra vigorous dwarf Roses, when required only for garden decoration as opposed to exhibition, as if allowed, they are often capable of forming large bushes giving a greater wealth of bloom that can be got from bushes pruned in the orthodox fashion. Mrs. Wemyss Quinn, one of the earlier Pernetiana yellows, for example, has capabilities in this way if let alone. *Cumbrian.*

PLANTS NEW OR NOTEWORTHY.

HYPERICUM KOUYTCHENSE
(Wilson 256).

It has seemed to me strange that a plant collected by Mr. Ernest H. Wilson so far back as the year 1907, should have been so long without a name, and on writing to the famous collector asking him about it, I received a request for dried specimens of the plant for determination. In these days when so many plant collectors abound, and there are so many plants awaiting determination, it is always pleasant to replace a number with a name, but, alas, I am afraid that there are times when this may be done at the expense of convenience, for Mr. Wilson, with his ever ready courtesy and help, has now advised the name of this species, and relates that it suffers from the terrible name of Hypericum kouytchense, (Lévl.). Mr. Wilson terms this "an abominable name," and in this I concur heartily. He explains that it was coined by the French Roman Catholic Bishop Léveillé, and when he expresses the opinion that it would have been better had the worthy bishop been engaged in the matters of his cure, rather than "in twisting poor gardeners' tongues," I am inclined to think that every one of the readers of *The Gardeners' Chronicle* will heartily agree with this view. I am, however, recording the name for the benefit of those plant lovers who have this beautiful plant.

Among Hypericums, this species has a particular charm. In growth it forms a rounded hummock of darkish green leaves, and when its golden-yellow flowers appear, it is, indeed, "a thing of beauty," and one of the most attractive of its genus. A true shrub, flowering about the beginning of July, the medium-sized flowers are profusely borne, and it makes an ideal front rank plant for the shrubbery.

While dealing with plant nomenclature I venture to plead with the botanists who first give a name to a plant, to endeavour to render this in a way that it may be conveniently remembered, and pronounced with a measure of ease. Who, for instance, can properly wind their tongues around the name of the Chinese Mountain Ash that doubtfully rejoices in the terrible varietal name of "pohuashanensis"? It is difficult enough, in all faith, to even copy it down from print, and when it comes to pronouncing it—well, I do not wonder so many blunder over it. *E. Beckett, Aldenham Gardens, Elstree.*

INDOOR PLANTS.

HABROTHAMNUS.

The species of Habrothamnus are graceful, evergreen greenhouse plants from Mexico, with a branching, drooping habit of growth, producing from the points of their shoots handsome bunches of attractive flowers which open in succession over a long period. The natural habit of the plants is such that they can be grown in different ways, either as pyramids, or standards with drooping heads, in which latter form they are very effective for conservatory decoration; but perhaps they display their flowers best of all when trained on the roof of a cool greenhouse. They are good growers, succeeding well in a mixture of equal parts loam and peat with a moderate amount of sand.

Cuttings of young shoots about four inches long, taken off with a heel, placed singly in small pots filled with sandy peat, and stood in moderate heat, kept moist and shaded, will soon root. When rooted, pot them on into larger pots, keep them in a growing temperature, and give a little shade from bright sun. About the beginning of September, give more air, gradually accustom them to a lower temperature, and winter them in a house having a temperature of about 45° by night. Pot on into larger pots as they require it the following March and April, and keep the points of their shoots pinched out until the desired shape is attained, after which they may be left to flower, and will be found most useful. In the more favoured parts of the country H. (syn. Cestrum) elegans does fairly well planted out-of-doors, when given the shelter of a south-west wall. *J. N. McGoogan, Wisley.*

THE GENUS PRIMULA.

(*Continued from p.* 330.)

sikuensis (Balf. f.). Siku P.
(Cortusoides).

This richly-tinted, downy perennial is a subspecies of P. polyneura, Franch.; it produces a tuft of kidney-shaped or heart-shaped, elliptic blades about two inches long, on erect stalks from three to four inches long, clothed with long, shaggy hairs; margins divided into about nine palmate, bluntly-toothed lobes; both surfaces clothed with fairly long, glandular hairs. Flower stem hairy, four to six inches tall, bearing an umbel of reddish-purple blossoms, on glandular, downy stalks about three-quarters-of-an-inch long. Corolla tube about twice as long as the calyx.

Grows in shady places on the Siku range, in Kansu, north-western China.

Culture; As for P. sataniensis.

silaensis (Petitm.). Mount Sila P.
(Amethystina).

A beautiful, dwarf species with a tuft or rosette of smooth, non-mealy, papyrus-like leaves about one inch long, with oblong-oval blades truncate at the base and contracted into a short, winged stalk; margins edged with sharp teeth. Flower stem slender, two to four inches tall, bearing one to three deep bluish-purple blossoms in a terminal umbel, on stalks about one-eighth-of-an-inch long. Corolla widely bell-shaped, about five-eighths-of-an-inch across, with small, notched and toothed lobes.

This species is found on Mount Sila, between the Salween and Mekong Rivers, in Yunnan, western China, in moist, peaty soil.

Culture : As for P. amethystina.

SIMENSIS (Hochst.). Simen P. (Verticillata).

A handsome, robust, perennial sub-species of P. verticillata, Forsk., with a tuft of membranous, oval-elliptic, pointed leaves two to five inches long and one inch to two inches wide, narrowed to a short, broadly-winged stalk ; margins furnished with sharp, irregular teeth ; both surfaces smooth, or coated with meal. Flower stem four to twenty inches tall, bearing several superposed umbels of numerous yellow blossoms. Corolla about one-and-a-quarter inch across, with broadly oval, shallowly notched lobes ; tube cylindrical, slender, about one-and-a-quarter inch long. Introduced in 1870.

Grows in damp places on the mountains of Abyssinia, usually on limestone formations, in the provinces of Simen and Modjerate, reaching an elevation of about 11,000 feet above sea-level.

Var. eusimensis (Pax). Foliage more or less smooth and non-mealy ; large, often equalling the flower stem in length.

Var. farinosa (Schweinf.). Foliage more or less mealy, smaller, shorter than the flower stem.

Culture : As for P. floribunda. *A. W. Darnell.*

(*To be continued*).

NOTES FROM EDINBURGH.

October is not a month when one expects to see a great display of bloom in the rock garden, yet there are several subjects that are still prominent at this time.

Among the more important genera flowering now is Gentiana. Of this genus, Gentiana sino-ornata is without equal at this time of the year, with its hundreds of rich blue flowers ; even at this late season the beds of G. sino-ornata are still a wonderful sight. Gentiana Farreri is now finishing, although the recent fine weather has prolonged its flowering season, and one can still see the pale blue trumpets which have made this species so popular. Another species from western China, namely, G. Veitchiorum, is making quite a good display, although for colour and growth it cannot compete with either of the former. Gentiana Andrewsii, a native of North America, with dull blue, white-tipped flowers, helps to brighten a corner, and although the flowers do not open, the plant has a certain attractiveness of its own. The Willow Gentian, Gentiana asclepiadea, with its long, arching sprays of blue trumpets and bright green leaves, is still a worthy feature.

Primulas, unfortunately, are now over, with but one or two exceptions. Primula Mooreana is still prominent with its flat heads of purplish-blue flowers, while the giant Primula Florindae, although past its best, continues to flower cheerfully.

Of the other newer plants still in bloom, there is Dracocephalum Forrestii. This plant, collected by Mr. G. Forrest in western China, has pinnatifid leaves and great quantities of purplish-blue flowers arranged in whorls.

Among other late-flowering subjects in the rock garden, there are many of the older species worthy of attention. The small Polygonum vacciniifolium, covering the large boulders with its mat of green and brown and myriads of pale pink spikes, makes a pleasing picture. Along with this species, its coarser relative, P. affine, gives a certain amount of colour, with the reddish-brown spikes now forming seeds.

Composites continue to give a good display in their many genera. There is the dwarf Golden Rod, Solidago brachystachys, a mass of bright yellow flower heads withstanding all weathers ; the silvery-leaved Achillea ageratifolia, with pure white flower heads ; Odontospermum maritimum, with large, yellow flower heads and downy foliage ; and the very old Gazania splendens in all its glory, with the deep orange florets marked at the base. Unfortunately, the two latter are not quite hardy. Another tender subject giving a wonderful display at present is Verbena chamaedryfolia, with brilliant scarlet inflorescences borne above the bright green foliage.

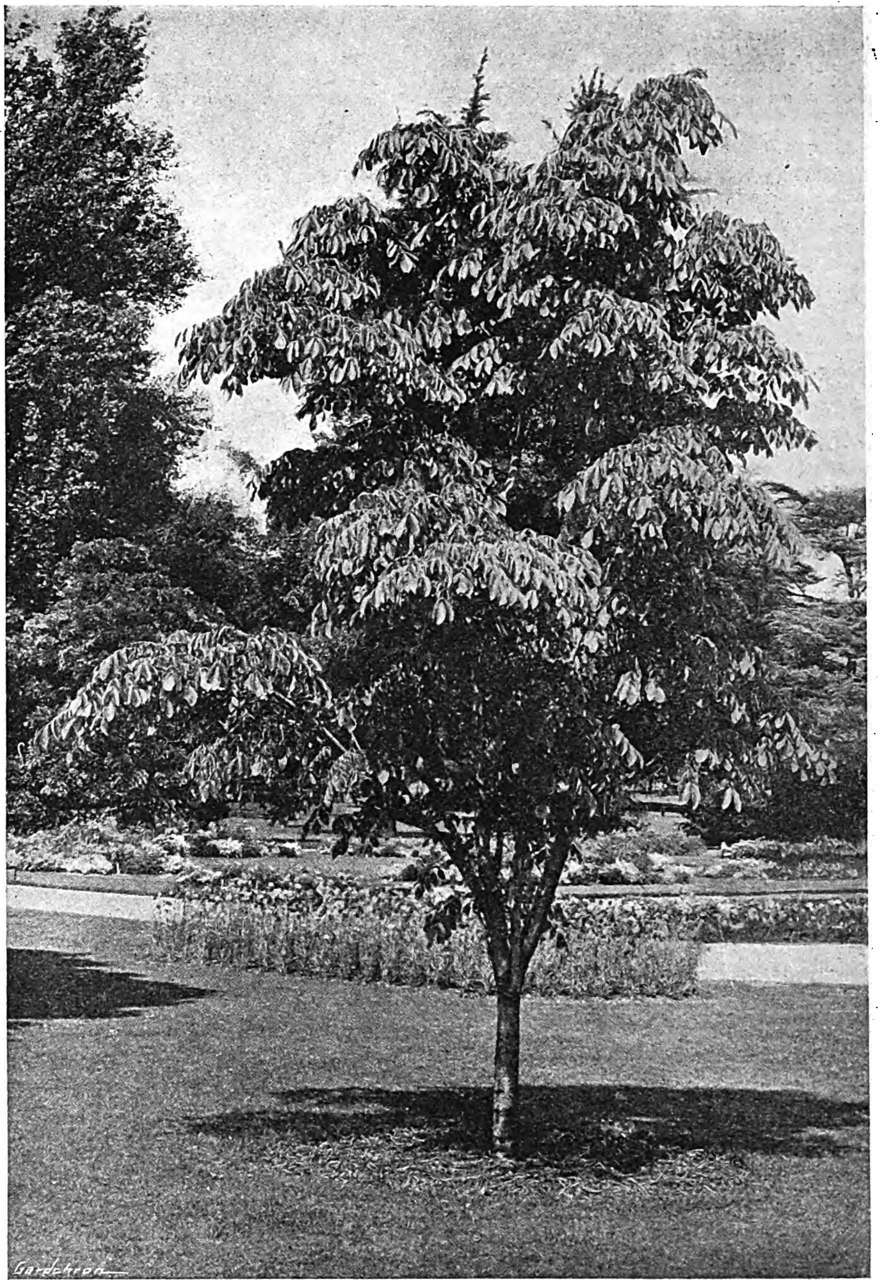

FIG. 160.—MELIOSMA OLDHAMII.

(see p. 347).

Many plants, although finished flowering, continue to beautify the rock garden with their fruits. This is very true of Clematis tangutica var. obtusiuscula, which has been allowed to ramble over the top of a mound, and is at present covered with its silvery seed-heads, among which can still be found several of the yellow flowers. Heaths and Heathers still do their share in the brightening of the mounds, the most noticeable being St. Dabeoc's Heath, Daboecia polifolia and its varieties ; Erica vagans var. kevernensis, and Erica stricta.

The dwarf Sea Holly, Eryngium prostratum, with its silvery bracts resembling collars, and purplish-blue heads, attracts attention. Although not so well coloured as some of its bigger brethren it is an outstanding plant with the flower stems radiating in all directions from the crown. On one of the lower beds, a clump of Astilbe chinensis var. pumila, with its dumpy, compact plumes, maintains its colour. Owing to the magenta shade of the flowers, this plant has not gained the popularity that the finer Astilbe simplicifolia hybrids have, yet it has many supporters. The popular Lithospermum prostratum and the Heavenly Blue variety, maintain a steady crop of flowers.

Among other floriferous plants, mention may be made of the Erodiums, especially Erodium chamaedryoides, from the Balearic Islands, and its variety rosea, both of which have kept up a succession of tiny flowers throughout the summer and are still struggling to maintain it. Many of the other Erodiums have done equally well, but they have not the neat and tidy habit of E. chamaedryoides.

The dwarf Violas, such as the varieties Lady Crisp and Pink Pearl, flower steadily on, and if the fine weather continues, should continue to brighten many places on the rock garden. *W. W., Royal Botanic Garden, Edinburgh.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

PROBLEMS OF PLANT LIFE.*

XII.—The Significance of Bloom.

In his anxiety to obtain light on this subject, Darwin addressed a letter to Dr. Asa Gray in June, 1877, in which he wrote :—

"I am now trying to make out the use or function of 'bloom,' or the waxy secretion on the leaves and fruits of plants, but am *very* doubtful whether I shall succeed. Can you give me any light? Are such plants commoner in warm than in colder climates? I ask because I often walk out in heavy rain, and very few wild Cotyledons can be here seen with drops of water rolling off them like quicksilver; whereas in my flower garden, greenhouse, and hothouses there are several. Again, are bloom-protected plants common on your *dry* western plains? Hooker *thinks* that they are common at the Cape of Good Hope. It is a puzzle to me if they are common under very dry climates, and I find bloom very common on the Acacias and Eucalypti of Australia. Some of the Eucalypti which do not appear to be covered with bloom have the epidermis protected by a layer of some substance which is dissolved in boiling alcohol. Are there any bloom-protected leaves or fruits in the Arctic regions?" He addressed similar questions to Professor A. de Candolle.

If such were the problems which so recently presented themselves to a man of wide scientific culture, what must have been the state of knowledge in general?

Although we do not possess copies of all the replies which Darwin received, we know that he was started on new lines of research by such authorities as Sir W. Thiselton Dyer, Dr. Hooker, F. Müller and others. Thus Hooker suggests that the waxy coat and hairs of plants subserve some purpose connected with the actinic or chemical rays of the sun, especially as the waxy secretion is often more conspicuous on the upper than on the lower surface of leaves. "I can quite fancy water impeding both the actinic and the calorific effects of sunlight on the leaf. We find watering most prejudicial in the hot sun. It is a splendid subject for experiments." Dr. Hooker adds that the prevalence of indumentum on the under surface of leaves is in some cases, perhaps, a provision against the attacks of insects. Such, too, he thinks, must be the use of wax and other secretions, and the end for which leaves and fruits are provided with crystals, acids and other active principles.

In 1887, Hillhouse's translation of Professor Strasburger's *Practical Botany* was published, and we were able to mark progress. It was found that 'bloom' was only one of many devices employed by plants for a great variety of ends. One must take along with it the study of gums, resins, crystals, hairs, glands, and other deposits and growths; and study not only leaves and fruits but buds, nodes, and every part of the plant. Strasburger took, for example, the winter bud of the Horse Chestnut with its secretion of gum and resin; the leaves of the Iris (I. florentina), the outer surface of the epidermis of which is covered with a fine, granular layer of wax, and such plants as Echeveria, Eucalyptus and the common Sugar Cane. The facts which he presents are full of interest, but the student is left to draw his own conclusions as to the ends which the secretions serve. No attempt is made to answer the question respecting the ends to be served, and for the pure botanist the problem is one apparently of no importance, He observes and records his observations, but that is all. It is just here that men like Darwin, Wallace, Romanes and similar enquirers come in to propound their queries and demand an answer. Without going further into the history of the subject during the last half-century, we may try to sum up some of the results of these investigations.

And first, a suggestion respecting bloom on fruits. It is a striking fact that purple fruits seem to be especially noteworthy in this respect. But why should purple Grapes, blue Plums, Sloes, the fruits of Mahonia, Whortleberries, and many other plants have this waxy coating, while related fruits which are yellow or red are left unprovided therewith? Here, undoubtedly, there is some relation between colour and the ultra-violet or other rays of light; and here, too, there is still room for careful research In relation to fruits we do not hesitate to say that the purple-coloured forms with a waxy secretion are able to utilise special light rays.

That bloom protects fruits, leaves and blossoms against pestilential germs, microbes, parasitic fungi and insect marauders is clear. Darwin removed the wax from leaves of a plant and syringed them with water at 95°. After a lapse of two days they were covered with a fungoid growth and looked as though they had been sprinkled with soot and water. The younger leaves, however, from which the bloom had not been removed were entirely unaffected, showing, it would seem, that spores cannot grow while the wax is intact. Where the secretion forms a thick layer, it might easily prevent insects from doing injury, especially if their mandibles are weak or easily clogged with a sticky substance.

In the next place, bloom checks evaporation, affects transpiration, and regulates temperature. Doubtless, Grapes and similar fruits benefit by the secretion which covers their fruits, since it keeps them from becoming too hot and dry. Stahl suggested, in 1897, that if moisture remains on the leaves of plants it checks transpiration. By lessening the activity of the plant and preventing the using up of the salts held in solution this would affect nutrition and interfere with the process of assimilation. And it is just here that there comes in the subject of nap, pile and hairs, as well as bloom. Darwin's work consisted largely in attempts to show that these things were primarily concerned, along with the voluntary movements of leaves, in throwing off superfluous moisture. He writes, in September, 1877, to Sir W. Thiselton Dyer to say he has clearly made out that with some plants, especially those which are succulent, bloom checks evaporation and diminishes transpiration. One obvious effect of the waxy coat or bloom and the layer of fine hairs was, he said, to keep off water. This end is clearly subserved in the case of such plants as the Bog-Bean, both by the gloss on the leaves and the fringe of hairs in the blossom. We may compare, also, the flowers of the Bog Pimpernel; but these plants will come up for consideration when we deal with the problem of the bog.

Where bloom is wanting, and the hairy pile is absent from fruits and leaves, a gloss is often present, which serves the same purpose. In one of his letters on the subject, Darwin remarks that when these are "immersed in water, they appear as if encased in thin glass. It is really a pretty sight (he adds, although the expression is not very well rendered) to put a pod of the common Pea, or a Raspberry into water," and everyone must agree that the appearance is remarkable.

In regard to the glaucous plants found in deserts and on the seashore, the ends to be served may be different. Shore plants might be injured by salt water if they were not protected by some resistent, while desert plants would respire too rapidly. On the latter point, a good deal has been discovered in recent years, but here a whole series of new problems is presented and to deal with these requires that we attack our subject from a new point of view. *Hilderic Friend.*

THE MELIOSMAS.

About fifty species of Meliosma, deciduous and evergreen trees and shrubs, have been named and described by botanists, but comparatively few of these are in cultivation. They are mostly natives of eastern and southern Asia, but are also represented in tropical America. The genus, it would appear, was represented by one species only out-of-doors in British gardens until the opening years of the present century. This was Meliosma myriantha, a Japanese and Korean species, first introduced by Maries in 1879.

In *Plantae Wilsonianae*, Mr. E. H. Wilson records that thirteen species are natives of China, eight with simple leaves and five with pinnate leaves. Of these, at least six are in cultivation in British gardens; M. Beaniana, M. cuneifolia, M. Oldhamii, M. pendens, M. tenuis and M. Veitchiorum—all introduced by Wilson. The Himalayan M. dilleniifolia, and M. myriantha were both introduced by Maries.

Cultivation.

I remember reading in *The Gardeners' Chronicle* some years ago a note by Mr. George Forrest on Meliosma cuneifolia. He described the shrub as "revelling in sunshine on the sheltered margins of deciduous forests, generally near streams or some other source of permanent moisture." Following this information, most of the Kew specimens are planted in positions where the ground and lower parts of the stems are sheltered from the fierce rays of the mid-day sun. They thrive in a good loamy soil with peat and leaf-mould added, and also plenty of coarse grit should the ground be close and heavy.

In the case of M. cuneifolia and M. myriantha, seeds are available as a means of propagation. There is no difficulty in layering or rooting cuttings of the simple-leaved species in a close propagating frame with slight bottom heat during July and August. It is also possible to root an occasional shoot of the pinnate-leaved species, but growths suitable for rooting are not numerous on plants grown in the open air.

The derivation of the name Meliosma is interesting, as it is from the Greek *meli*, honey, and *osma*, odor, in reference to the honey-like fragrance of the flowers.

M. Beaniana, Rehd. and Wils.

According to Mr. Wilson, this is one of the handsomest and most striking of Chinese trees. He describes it as thirty-six to seventy-five feet in height, nowhere common, but occurring scattered throughout western Hupeh and Szechuan, at altitudes of between 3,000 and 4,500 feet. The pinnate leaves are five to ten inches long, with five to thirteen ovate to elliptic-lanceolate leaflets, averaging two to two-and-a-half inches long and one inch broad, with axillary tufts of hairs beneath. We await with interest the first flowering of this tree in our gardens, as Mr. Wilson describes it as a remarkable and well-marked species.

---

* Previous studies appeared in our issues of April 13 (p. 279). June 15 (p. 446), Vol. LXXXV; July 13 (p. 30). July 20 (p. 50), July 27 (p. 71); August 17 (p. 130), September 7 (p. 187), September 14 (p. 207), September 28 (p. 247), October 5 (p. 268), and October 12 (p. 288).

The tree is distinguished at once in flower from all other members of the genus by its precocious blooms, borne in axillary panicles. They are creamy-white, and relatively large for the genus. The spreading and pendulous panicles four to six inches long and two to four inches in diameter, are strikingly conspicuous on the wild trees in May before the full development of the leaves.

The specimen of this Meliosma at Kew was raised in 1908 from seeds (Wilson 258) collected by Mr. Wilson in western Hupeh in September, 1907. It is now twelve feet six inches in height and ten feet through the branches at their widest part.

Mr. Wilson records M. Beaniana as associated with temples and wayside shrines. In Hupeh, the tree is colloquially known as the Ku-ku-lan-shu.

M. PENDENS, Rehd. and Wils.

This is one of the simple-leaved species most closely related to M. cuneifolia, but it has drooping flower panicles and the bushes are not so vigorous in habit.

Wild bushes average from nine to fifteen feet in height. The leaves are elliptic-obovate, three to six inches long and one-and-a-half inch to two-and-a-half inches wide, with twelve to twenty pairs of prominent veins. This species lacks the tufts of hairs conspicuous in the axils of the veins of M. cuneifolia. The terminal panicles of small, fragrant, white blossoms develop during July. They are pendent—hence the specific name—averaging five or six inches long and four to five inches wide. The small, Pea-like fruits are black when ripe.

Mr. Wilson introduced this Meliosma by means of seeds collected in western Hupeh, in 1907, where the species grows at 2,000 feet to 4,000 feet elevation.

M. VEITCHIORUM, Hemsley.

As an ornamental deciduous tree, hardy in our gardens, this is the most remarkable of all Meliosmas (Fig. 161). It is an upright-growing tree of stout appearance, thirty to forty-five feet high, with remarkably distinct, pinnate leaves. These are fifteen to thirty inches long averaging nine or eleven leaflets, ovate to ovate-oblong, three to seven inches long. Mr. Wilson describes the flowers as greenish-yellow, and honey-scented, produced in much-branched, pendulous panicles, seven to twenty inches long, and six to twelve inches wide at the base. The fruits are black.

M. Veitchiorum was described from dried specimens collected by Mr. Wilson in Eastern Szechuan, in June, 1901. The first plants cultivated were raised from seeds collected by Mr. Wilson later, in the same year, the Wilson-Veitch number being 754.

Two vigorous young trees are growing at Kew, one obtained from the Coombe Wood nursery in 1909, and a second in 1913. The taller of the two trees is nineteen feet in height.

Mr. Wilson describes this very distinct and interesting tree as abundant in the moist woods throughout Hsing-shan Hsien and Fang Hsien, in Hupeh, but it is not recorded from western Szechuan. It occurs at elevations between 4,000 and 7,500 feet. Having passed quite untouched through the severe frosts experienced last winter, it is evidently a hardy tree. It has a relatively thick trunk and branches, with the strikingly large, pinnate leaves clustered at the ends of the rigid branches.

M. OLDHAMII, Miquel.

This pinnate-leaved species is named in compliment to Richard Oldham, a Kew collector, who discovered this Meliosma in the Korean Archipelego in 1863. Pére Farges collected it in Szechuan, and Dr. A. Henry in Hupeh. The tree illustrated (Fig. 160) was raised from seeds collected by Mr. Wilson in 1900. He describes the tree as up to sixty feet high with a girth of seven to eight feet. It occurs in moist woods and thickets in western Hupeh, at an elevation of from 3,000 to 4,500 feet. As the illustration indicates, in young trees the branches are inclined to be somewhat erect in growth, but Mr. Wilson describes the old trees in a wild state as widespreading, with symmetrical heads.

The pinnate leaves are from six to fifteen inches long composed of five to eleven leaflets. The leaflets vary in size on a leaf, the lowest pair being about one inch long and three-quarters-of-an-inch wide, increasing in size along the leaflet, the terminal one being in-

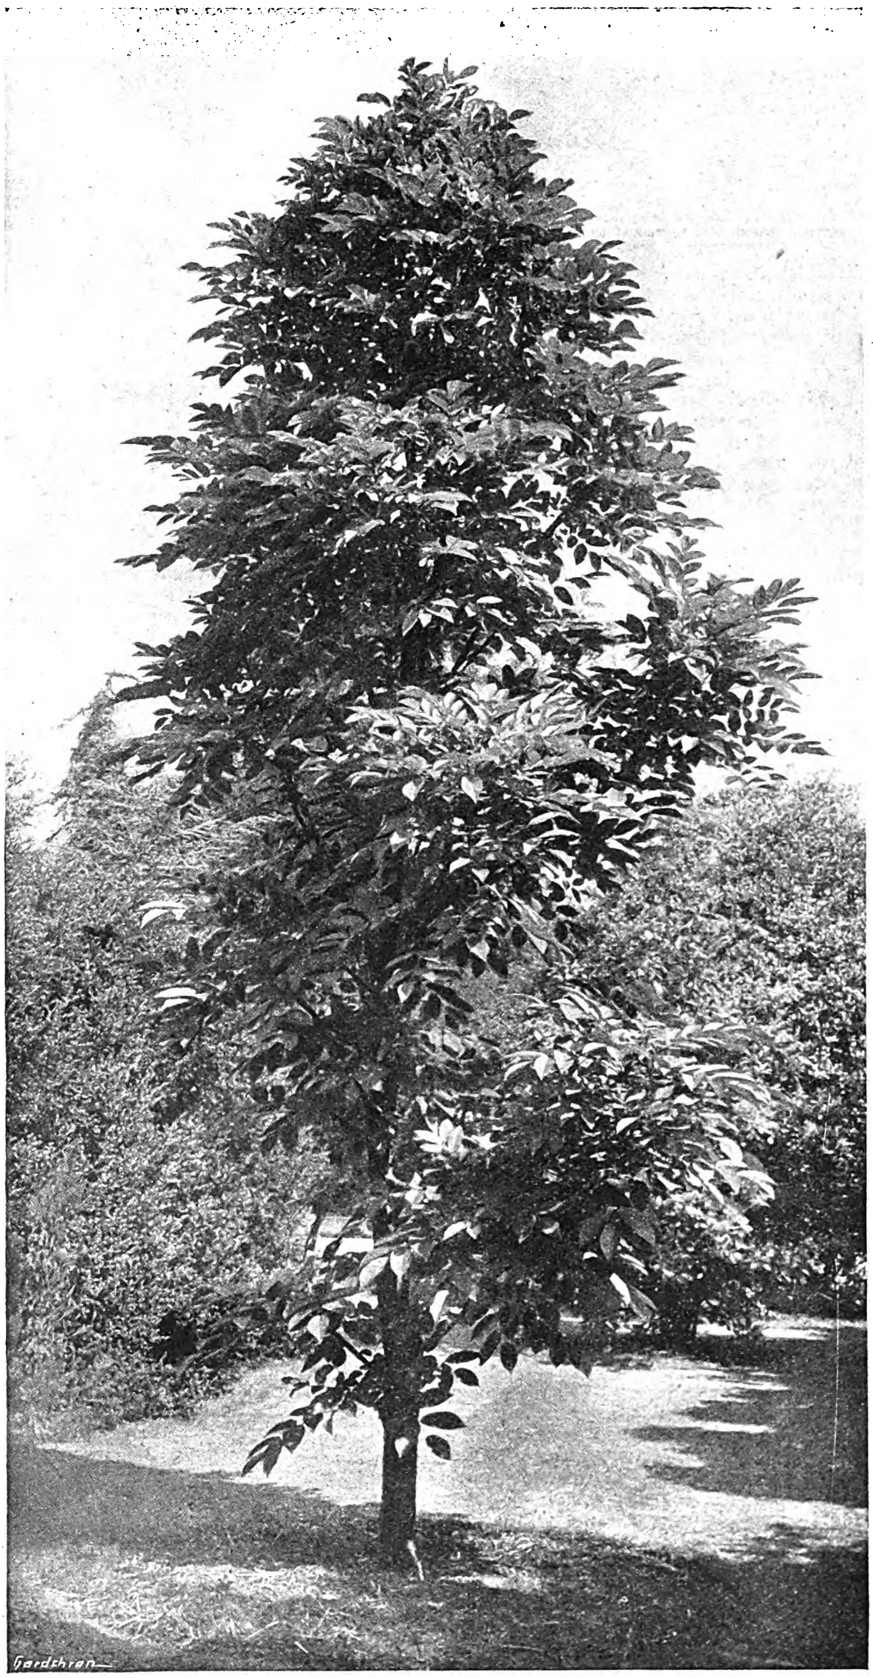

FIG. 161.—MELIOSMA VEITCHIORUM.

variably the largest, up to five inches long and two inches wide.

Dried wild specimens indicate the inflorescence to consist of a terminal panicle, with smaller panicles in the axils of the upper leaves, the whole being from about five to nine inches long and broad. The very small, pure white flowers are fragrant and very freely produced in June, when the leaves are nearly fully-grown.

The tree of M. Oldhamii was presented to Kew by Messrs. J. Veitch and Sons in 1913, from the Coombe Wood nursery, and was raised from seeds collected in September, 1900, during the first Wilson-Veitch expedition. The tree is now fifteen feet nine inches in height.

M. CUNEIFOLIA, Franchet.

Mr. E. H. Wilson describes this species as exceedingly common throughout western Hupeh and Szechuan, growing in thickets and on the margins of woods at from 3,000 to 4,500 feet altitude. Mr. George Forrest found it on the southern flank of the Lichiang range at from 8,500 to 10,000 feet. It occurs as a large bush or small tree, up to twenty-four feet high, rarely as much as thirty feet in height. Mr. Wilson collected his first seeds of this species in 1900, and the first plants flowered in the Coombe Wood nursery of Messrs. J. Veitch and Sons in July, 1909.

It is a simple-leaved species; the leaves are obovate, four to seven inches long, and two to three inches across at the widest part, dark green above, paler beneath, with twenty to twenty-five pairs of prominent veins and tufts of down in the axils of the veins.

The small, creamy-white, or white flowers, are produced very freely during July at the ends of the growths of the year in large, pyramidal panicles up to seven or eight inches long, and nearly as much through. The flowers are powerfully fragrant with a honey or Hawthorn-like fragrance. The small, Pea-like fruits are black and mature ripe seeds which provide a ready means of increase, as also do half-ripe shoots inserted as cuttings in a sand frame during July or early August.

M. cuneifolia makes an attractive lawn shrub for a sheltered position, forming as it does a bush of spreading habit. The best specimen at Kew is twelve feet high, and almost as much in diameter. It is illustrated (Fig. 159) and was obtained for Kew from the Coombe Wood nursery in 1910. As the figure suggests, M. cuneifolia is closely allied to the Japanese and Korean M. myriantha, but it is much hardier, and is readily distinguished by the cuneate leaf.

M. MYRIANTHA, Sieb. and Zucc.

This interesting Meliosma is a native of Japan and the Korean Archipelago. It was first introduced from Japan by Maries in 1879 when collecting on behalf of Messrs. J. Veitch and Sons. The bush first flowered in their Coombe Wood nursery in 1893. The best specimen I have seen, other than the one at Coombe Wood, is growing at Grayswood Hill, Haslemere, where it flowers freely and ripens fruits.

M. myriantha forms a large, rather spreading, deciduous bush or small tree up to some twenty feet in height. The oval-lanceolate leaves are up to eight inches long and three inches wide. The veins of the leaves vary from twenty to thirty pairs. The terminal panicles of yellowish-white flowers are produced at the end of June and although small are very fragrant.

It is only in sheltered gardens and warm districts that M. myriantha is really satisfactory. Plants grow in sheltered positions outside at Kew for a few years but succumb during severe winters.

M. TENUIS, Maxim.

This Japanese Meliosma was introduced in 1915. It belongs to the simple-leaved group and has prominently-toothed leaves, one inch to three-and-a-half inches long, with ten to fifteen pairs of veins.

A plant growing on a sheltered south border at Kew failed to survive the severe frost of last winter, thus proving it is not to be compared in hardiness with the Chinese species. M. tenuis may only be expected to thrive really well in the sheltered gardens of the south and west, where another Japanese species, M. myriantha, flowers and fruits freely.

M. DILLENIIFOLIA, Wall.

This Himalayan species was introduced to cultivation in 1924. The Kew specimen was received from the Arnold Arboretum in 1927.

It is described as a small tree up to twenty feet in height. The simple leaves are obovate to oblanceolate.

The plant does not appear to be so hardy as the Chinese species, being more comparable in this respect with the Japanese M. myriantha, and, in common with that species, cuttings are easier to root than are those of the pinnate-leaved species. *A. Osborn, Kew.*

AN ENGLISH GARDENER IN CHILI.

(*Concluded from p.* 328.)

A CHUSQUEA, known as Coligue, grows so rank that it is impossible to force a way through it, and not content with that it climbs up among the branches and in some parts simply smothers everything else. It is peculiar in that its stems are not hollow as in most Gramineae.

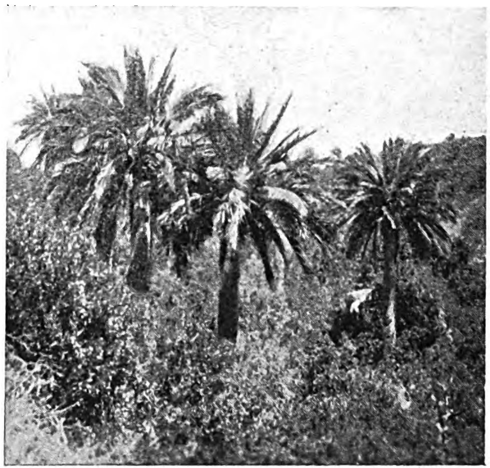

FIG. 162.—GROUP OF JUBAEA SPECTABILIS NEAR EL SALTO, CHILI.

The undergrowth of these slopes is both varied and interesting; in the shady parts a brilliantly-flowered shrub with butterfly-like, orange flowers makes splashes of colour. It certainly belongs to the Leguminosae, and, I believe, is Cassia stipulacea; this grows about six feet tall and appears to require a moist, although well-drained and shady position. These conditions also suit to perfection a large species of Adiantum, which carries fronds two feet high and broad in proportion, and which grows here by the acre.

In slightly more open and sunny positions there are quantities of a scarlet Amaryllid, probably Hippeastrum bicolor (syn. Phycella ignea). The earliest flowers are distinctly bicolored, green towards the ovary, but later in the season are practically pure scarlet. Another of the very earliest spring flowers is Tropaeolum tricolor; this climbs by means of its flexible leaf-petioles which curl around branches or twigs; it covers comparatively ugly, leathery-leaved evergreen shrubs with festoons of bright green leaves and small, scarlet flowers set on long, slender peduncles. The thin rhizomes spread about among the fallen leaves and roots of the undergrowth making it almost impossible to lift this treasure successfully, while it is almost as difficult to obtain seeds, as its flowers disappear in an incredibly short time. The same remarks apply equally to the less common yellow-flowered species, Tropaeolum brachyceras.

In open, sunny situations various species of Alströmeria flourish, but I am not sure as to their identity. The best I have seen is two feet high, or even more, when growing in gravel, where it receives water in the growing season and is bone-dry afterwards; its flowers are brilliant orange, with the two lateral perianth segments yellow, flaked with scarlet; and the compound umbels bear fifteen to twenty large blooms. A low-growing species has white flowers with a yellow zone in the centre of the lateral pair of segments. There are also a salmon-pink, self-coloured kind which is quite common, and a maritime species which has large, bright rose and white flowers. Among other more lowly subjects which are worthy of note here, is a violet Anemone with solitary flowers about six inches high, a bright carmine Oxalis (perennial) common in some localities, and a well-known greenhouse subject, Alonsoa incisifolia.

Towards the top of these slopes, where they merge into the comparatively flat land, and are protected from the full force of the winds but receive full sun, are frequent open spaces, and it is in these that some of the most beautiful of Chilian wild flowers are to be found.

One of the prettiest and earliest to flower is the tall-growing Pasithea coerulea, a monotypic herbaceous perennial, belonging to the Liliaceae; the foliage is equitant, not unlike that of some Sisyrinchiums, but more arching and less tough in texture; the inflorescence is three feet to five feet high, erect, somewhat stiff in habit, and carrying numerous, star-like, clear blue flowers about an inch in diameter. The root system closely resembles that of another well-known Liliaceous plant—Asparagus Sprengeri—while the thin, wiry, fibrous roots swell out into small, fleshy, elliptical tubers which enable the plant to survive the long drought. In company with this are found three other good blue flowers, the brilliant little Triptilion spinosum, which forms compact clumps of blue six to twelve inches high; Tecophilaea violaeflora, also low-growing, the flowers being generally (although not always) solitary, arising from the centre of a single linear "leaf," about six inches long by three-eighths-of-an-inch wide, in a manner suggestive of a small Tulip; this little plant makes up in profusion what it lacks in size.

The third of this trio is a bulbous subject about one foot high which I believe to be Conanthera bifolia; the inflorescence is produced in the absence of leaves, as these are produced early, matured and dried off before the flowering period. It is a most variable plant; in some cases it has campanulate flowers of deep violet, while in others the colour is light blue, with reflexed perianth segments, and the stamens projecting forward in exactly the same manner as those of the Potato flower. At first I thought them distinct species, but there are intermediate forms and colours and the bulbs appear to be identical. There are numerous other bulbous plants belonging to both Liliaceae and Amaryllidaceae, Scilla chloroleuca being the most common, while a white species of Leucocoryne is pretty, but marred by its strong Alliaceous odour.

Several species of terrestrial Orchids thrive on these banks, especially on heavy loam and gravel; three of them I consider worthy of cultivation, and the others at least rank equal with our native Orchids. The best of these I believe to be Chloraea aurantiaca, which grows two feet to three feet high, the spike carrying so many as ten or twelve large, golden flowers, each fully two inches across; the labellum is lined with dark green excrescences, and the tips of the lateral perianth segments are dark green. A white species, equally as vigorous but not so tall (Chloraea ulanthoides) has flowers as large but more enclosed and funnel-shaped, the guide lines on the labellum being dark green; there are dark blotches at the tips of the labellum and each of the two lateral perianth segments, while the whole is beautifully lined and shaded with green. The third species is more curious than beautiful, the labellum and two perianth segments being white, shaded and lined with green, the other three being green, the dorsal one arching over the centre while the two lateral segments spread out and have long fringes, giving the whole inflorescence a most curious appearance. This is Bipinnula mystacina. All these have fleshy roots about as thick as a finger and four inches to six inches long; they flower and seed in early summer and die off completely until the first rain of the following winter. In conclusion, I would like to add that I have brought back seeds of the Orchids and several other subjects mentioned, and would be pleased to distribute them among those especially interested. *G. Robinson.*

VEGETABLES AND FRUITS IN USE IN THE EIGHTEENTH CENTURY.

There is no doubt that, to the great benefit of the health of the nation, the English people have been gradually learning the value of vegetable foods.

In the days of Queen Anne, when a Sussex gentleman invited a dozen neighbours to dine, his idea of hospitality was meat, meat, and more meat! The meal began with "Plum pottage"—the very strongest beef broth, enlivened with Currants and spice. Two whole roast pigs were served, a boiled leg of mutton, a roast leg of veal, boiled beef, a goose and four fowls! This was washed down with a fearful amount of strongly alcoholic drinks. No wonder that the guests required to be "blooded" frequently, and that scurvy and similar diseases were prevalent.

In a quaint old cookery book, *The Experienced English Housekeeper*, published in 1773, and signed (in a very illiterate scrawl) by the author; Elizabeth Raffald dedicates her work in a tone of fulsome flattery to her late mistress, Lady Elizabeth Warburton, begging her to excuse the "plainness of the style" as "I have studied to express myself to be understood by the meanest capacity." It ends, "I think myself happy in being allowed the honour of subscribing, Madam, your Ladyship's most dutiful, most obedient, and most humble servant!" Truly methods of expression have moderated, so well as meat consumption! The author had considerable faith in the "meanest capacity," for in the nine hundred original recipes, no time needed for cooking is mentioned, although in making "German puffs"—the modern dough nut—directions are given to "beat them an hour or more," before frying.

A large number of the recipes are for absurdly elaborate sweet dishes—"How to make a Solomon's Temple", or "a Thatched House pye," and cover them with "cages made of spun sugar." The richness of the edibles sounds terrible to modern digestive powers:—"Twelve yolks of eggs" in a single pudding, and a whole pound of butter in the sauce! "A common custard" was to be made of a quart of cream and eight yolks of eggs. Economy was quite beneath the author's consideration, but, of course, eggs and cream were cheaper in those days, although the imported eatables—sugar, raisins, spice and the multitude of Lemons used—must have been a costly item in the household budget.

The recipes for cooking vegetables are very few. Potatos are only once mentioned, when they are to be scalloped with much butter and browned in a Dutch oven. Evidently that most useful of vegetables was not in common use, although the plant had been brought to Europe in the sixteenth century.

We have heard of English folk newly returned from the Continent rejoicing in "a nice, clean, boiled Potato," without other flavourings, and the present taste would not approve of Mrs. Raffald's recipe for stewing Celery with "a slice of Lemon a little beaten mace, a good lump of butter, the yolks of two eggs, half a nutmeg grated, and a tea-cup of good cream." Parsnips, also, were to be beaten up with butter and cream to resemble a very light custard. The recipes for boiling Cabbage, "Colly flower" and French Beans all end with advice to serve them with "very rich melted butter." Windsor Beans, in addition to this, might "be served with bacon in the middle, if you choose it."

Almost the only recipe which mentions Lettuces directs that they shall be cut in slices and fried in fresh butter, and dished up with green Peas, in good gravy, flour and butter. Spinach was to be first boiled, then fried in butter pressed between two pewter plates, and covered with poached eggs. Cucumbers, after being fried in fresh butter, were to be covered with a large glass of red wine, strong gravy, mace, and a good thickening of flour and butter. Asparagus was served on bread, with butter sauce, much as it is now, and for an "Asparagus amulet"—which was Mrs. Raffald's way of spelling omelette—the boiled tips were fried with eggs and served on buttered toast.

The only hint of vegetarian cookery is an "Herb pye for Lent." "Take Lettuce, Leeks, Spinage, Beets and Parsley of each a handful, give them a boil, then chop them small, and have ready boiled in a cloth one quart of groats, with two or three Onions in them, put them in a frying-pan with the herbs, and a good deal of salt, a pound of butter, and a few Apples cut thin, stew them over the fire, fill your dish or raised crust with it. Bake it, then serve it up." Large Spanish Onions are mentioned as a soup ingredient, but there is no recipe for cooking them as a vegetable.

At the end of the book—as in modern publications—there are lists of food in season, and here only Jerusalem Artichokes are mentioned; but the other Artichokes, of which the large flower heads are the edible part, have several elaborate methods of cooking devoted to. The seasonable lists are puzzling, for although hot-houses are only mentioned in January for Cucumbers, one could hardly expect to find Endive, Lettuces, Mint, Asparagus and Mushrooms in the open air at that bleak season.

Several of the vegetables and herbs cited have now practically passed out of use, such as Hyssop, Tansy, Skirrets, Scorzonera, Rocambole, Tragopogon—the latter, I imagine, a relative of the wild Meadow Salsify, or "John-go-to-bed-at-noon." Finocks and Purslane are in the July list, Cardoons and Charbeets in October.

The fruits given remain much the same except that Medlars are not now popular, and few would care to eat Service Berries, when sleepy, like an over-ripe Pear, as the writer had done many years ago. "Lazaroles", too, is an unknown kind of fruit. In those pre-game-law days, pheasants were "seasonable in July and August," but partridges are not mentioned until September. Oysters are not given in March or April, but otherwise they follow the present rule of being in season "when there is an 'r' in the month."

There is a simple recipe for Apple dumplings, but Gooseberry pudding is a wonderful concoction of mashed fruit, sugar, Naples biscuits, six eggs, and the inevitable "half-pound of butter." Our ancestors must have had a great liking for greasy dishes. Apple fritters are much as at present, except that a modern cook would prefer milk to ale for the batter, but the next recipe is puzzling—"Clary fritters," when dried leaves of Clary were dipped in batter and fried. What we now call Clary is the blue wild Sage, and one would not imagine that the flavour of Sage leaves would combine well with cream, sugar, Nutmeg and Seville Oranges A Tansy fritter was to have only the juice of that aromatic herb, with a warning not to use too much, as it will make the pancake bitter.

One surprising recipe is a Yam pudding. It seems strange that Yams should have been imported in those far-off days. "A middling white Yam" was to be pounded with three-quarters-of-a-pound of butter, twelve eggs, Rose-water, mace, Cinnamon and Citron. When it comes to pickles and preserves, Mrs. Raffald is in her glory. "Colly flowers," Walnuts, Nasturtiums, Radish pods, Parsley and Samphire as well as Red Cabbage and Onions, were scalded in "allegar" with many flavourings, but Walnuts in syrup seems a curious dainty. Two kinds of pickle were made from Elder shoots and Elder buds, flavoured with Mustard seed and Horse Radish.

One chapter is devoted to "Possets—broths and gruels." I imagine this is sick-room cookery, but here, again, a quart of cream and six eggs with a glass of brandy would be rather strong meat for the average invalid.

Not only Mushrooms, but Truffles and Morels are frequently mentioned for flavouring of meat pies and "Ragoos." These would not often be obtainable, for the Morel, a rare fungus, looking like a piece of coarse, drab sponge, is only to be found near woods in early summer, although they might be dried. No mention is made of stewed fruit, or of salads, and it is evident that vegetables and fruits were but a small item in the diet of our ancestors two hundred years ago. *Maude Robinson.*

NOTICES OF BOOKS.

Garden Design.

In this book* on garden construction and design we have an example of the result of that most difficult and most unsatisfying of tasks—the making of a new book out of the materials used in an old one. Such a book has neither the interest of antiquity nor the freshness of youth; it is too apt to retain the faults and drawbacks of the original, while adding thereto the lacunae and inaccuracies commonly incidental to the first edition of any technical work, but M. Péan has apparently undertaken his task—that of revising and bringing up to date the work of his father, the late Armand Péan, *L'Architecte Paysagiste*—from motives of filial piety, but we cannot help thinking it would have been more satisfactory to himself to have written a completely new book, which would have been more likely to interpret correctly modern French ideas on gardens and garden-making. That he has the capacity and the qualifications for such a work there can be no doubt; as a landscape gardener he has a well-merited reputation, and has had considerable experience in his métier. That he should, as it were, conceal his own reputation behind that of the late Armand Péan is a sign of praiseworthy modesty, no doubt; but modesty finds so little appreciation nowadays, and is especially so little looked for in authors, that we fear none of the readers of the book will attribute its defects to such a cause.

Of these defects, the worst is the very one which its title would least lead one to expect, namely, its want of modernity. Except for a few photographs thrown in together at the very end, without any coherence, or relevance to the text, the illustrations are all wood-cuts, the overwhelming proportion being reproductions of formal gardens of the eighteenth century. As practically no reference is made to them in the text, it is difficult to ascertain whether these are inserted as examples to follow, or as warnings of the sort of thing to avoid. The position of the illustrations is no less irrelevant than their nature. For instance, there is a section, in the part of the book entitled "Pratique," on the instruments to be used in surveying. No illustrations of these instruments appear or are referred to in the article, and the reader is not encouraged to hope he will find them elsewhere, for on p. 67 we read:—"*Nous n'avons pas a faire ici un cours de topographie, il en existe d'ailleurs d'excellents.*" This would seem to indicate that a special book on the subject should be consulted; nevertheless, on reaching p. 203, we find, not only a quite good and detailed chapter on topography, but illustrations of all the instruments mentioned both there and in the article on surveying on pp. 66-68! No doubt this confusion is one of the many evil consequences which follow on the addition of subsequent matter to a book, without a perfect revision of the original text. The only illustration with which the chapter on surveying is enlivened is a plan resembling at first glance an ornate tea-tray, which, on consulting the caption turns out to be "*Parterre d'Orangerie (xviiie siècle) d'après Galimard.*"

---

* *Le Nouveau Jardiniste Moderne.* Par Prosper Péan. Paris, Librairie de la Construction Moderne, 13, Rue de l'Odéon.

In the chapter on the drawing of plans, one would expect from a practical garden-architect some useful lessons for the beginner, as well as advanced instruction from which a qualified designer could benefit, but the section is disappointing. Some model plans are indeed given, but they are far too detailed and fussy for modern use, and only one set is supplied, unless one can count eleven illustrations of gardens and parts of gardens, none of them less than a hundred years old. A few really simple plans for the laying out and planting of small and unambitious pieces of ground would have been infinitely more informative. Incidentally, in recommending colours for use of plans, the writer mentions Rowney's, but does not seem to have heard of Winsor and Newton. In giving directions for the clearing of a waste space and removal of surplus ground, he assumes that horse-traction will be the only alternative to man-power; the use of the now ubiquitous motor-lorry would appear to be outside his cognisance.

The chapter on legislation as it affects the surveyor and landscape gardener is interesting, and if up-to-date, useful, but as no legislation later than 1898 is mentioned, it would probably be safer to consult a good lawyer than to rely on the information given in this chapter in case of litigation. Chapters VIII and IX are devoted to the fees earned by the landscape gardener, and the proper way to draw up an estimate and render an account. These contain quite useful information, although, as the scale of fees is based on a scale drawn up in 1921, we fear that for present use it would require modification.

By way of bibliography, or, perhaps, merely with the idea of letting his readers know of the existence of books which would interest them, the author gives a partial list of works on gardens—with and without illustrations—which have appeared up to the end of the nineteenth century. Why he should have stopped short here is not very clear; he states, as a reason, that books published after 1900 are well-known, and easy to find, but it would certainly have enriched the list if it had contained for instance, the works of Thomas Mawson, in this country, and of Willy Lange, in Germany. Since the beginning of the present century, and especially since the war, the art of landscape gardening has made tremendous strides, and the date of publication of M. Péan's book finds more than a quarter of the century already elapsed.

In his introduction, the author expresses the hope that his book will interest amateurs, and facilitate the entry of young students into the career of garden-architect. We think it unlikely that the book will wholly fulfil all his kindly aspirations, but we are nevertheless willing to believe that M. Péan's students find him, in personal contact, an enthusiastic and stimulating teacher. We suspect that he is a Parisian through and through; all his photographs are those of Parisian gardens, although had he taken his subjects from other parts of France, he could have found far better and more characteristic examples of modern garden-making. That he has wit and humour we are sure, in spite of the somewhat indigestible nature of the twice-baked dish he has set before us. We can cordially endorse the opinion expressed on p. ix that "*Un petit grain de folie n'est pas à redouter, dans les arts, en général; le tout est de ne pas dépasser les limites*" which can be very freely rendered by "Art in general is none the worse for a little eccentricity, only it must not be overdone."

There is the usual crop of printer's errors, and it is a pity that there is no alphabetical index. These are defects which could easily be put right in a future edition, but we hope that before long we may look, not for a further edition of the present work, but for a completely new book which will give us M. Prosper Péan's own opinions, and provide us with the opportunity of profiting by his own studies and experiences.

Plant Pests and Diseases.[*]

The three volumes on pests and diseases of fruits have now appeared in the series of illustrated booklets published by Paul Parey, of Berlin, of which the first series dealt with Potatos and other root crops. The library of the smaller gardener is not too well supplied with illustrated works on pests and diseases, and to those who can read German easily the three little volumes under review will make a welcome addition to their gardening literature, for they are well got up, the coloured illustrations, of which there is one to every page of text, are beyond all praise, and the letterpress is clear and lucid. It is not, however, possible to pass over the drawbacks inherent in the series, which are not inconsiderable. In our opinion, the arrangement of the books is lacking in clarity, although obviously any system would be open to criticism on one point or another. The method, indeed, varies in the different volumes, which seems to point to a doubt even in the author's mind. Numbers IV and V are arranged according to the parts of the tree attacked, *e.g.*, bud and shoot pests, leaf-eaters, etc. In Number VI the arrangement—to our minds, greatly preferable—is according to the kind of tree, namely, "Diseases of the Strawberry," "Diseases of the Raspberry," and so on. The disadvantage of the former method is that in order to assemble the various diseases from one of which, for example, a sickly Apple tree may be suffering, it is necessary to search all through the volume, for there is no index in any of the three, merely a list of the coloured plates at the beginning. The illustrations, as we have stated, are excellent, but sometimes rather too crowded, doubtless in order to keep the books down to handy dimensions. Some of the statements made require a little qualification—for instance, that silver-leaf is liable to appear on all fruit trees—but on the whole, the books contain reliable information and advice. Numbers IV and V have several pages of advertisements in the end, but number VI appears without this blemish, which, perhaps, accounts for its higher price.

ADDITIONS TO THE LINDLEY LIBRARY.

The following books and pamphlets were added to the Royal Horticultural Society's Lindley Library during the half-year ending June 30, 1929.

Adie, R. H. *Chemistry for Agricultural Students.* Illus. 8vo. 1926.

Agar, Madeline. *Garden Design in Theory and Practice.* 2nd ed. rev. Col. pls. Illus. 8vo. 1913.

Allen, Grant. *Flowers and their Pedigrees.* 2nd. ed. Illus. 8vo. 1886.

Annals of Botany. Editors C. Konig and J. Sims. 2 vols. Illus. 8vo. 180[4]-1806.

Glanck, E. [Ed.] *Handbuch der Bodenlehre.* Vols. 1-2. 8vo. Berlin, 1929.

Blatter, Ethelbert. *Beautiful Flowers of Kashmir.* Vol. 2. Col. pls. 8vo. 1928.

Bois, D. *Les plantes alimentaires chez tous les peuples et à travers les âges. Histoire, utilisation, culture.* Vol. 2. Phanérogames fruitières (*Encyc. Biol.*, iii). Illus. 8vo. Paris, 1928.

Bonnier, Gaston. *Flore complète illustrée en couleurs de France, Suisse et Belgique.* Vol. 10, par Robert Douin. Col. pls. 4to. Paris [1929].

Bose, Sir Jagadis Chunder. *The Motor Mechanism of Plants.* Illus. 8vo. 1928.

British Gladiolus Society, The. *The Gladiolus Annual,* 1929.

Calvert, Albert F. *Daffodil Growing for Pleasure and Profit.* (Two copies). Illus. 8vo. 1929.

Canada. *Wild Flowers of Canada.* By Special Artists and Botanists. Col. illus. Obl. 4to. Montreal [1890].

Cavers, F. *School Certificate Botany* . . 2nd. ed. (9th impr.). Illus. 8vo. 1926.

Clint, Hilda, B. *The Life History and Cytology of Sphacelaria bipinnata, Sauv.* (Publ. Hartley Bot. Lab., No. 3.) Illus. fol. Liverpool, 1927.

Cockayne, L., and Turner, E. Phillips. *The Trees of New Zealand.* Illus. 8vo. Wellington, 1928.

Combes, Raoul. *La vie de la cellule végétable.* 8vo. Paris, 1929.

Crowfoot, Grace M. *Flowering Plants of Northern and Central Sudan.* Introduction by A. F. Broun. Illus. 8vo. [1928].

Daglish, E. Fitch. *The Book of Garden Animals.* Illus. 8vo. 1928.

Davis, Kary C. (*Ed.*]. *Horticulture Enterprises.* Illus. 8vo. Philadelphia, 1929.

Deutsches Magazin für Garten-und Blumenkunde. Vols. 1-34. Col. pls. Illus. 8vo. Stuttgart, 1848-81; continued as *Dr. Neuber's Deutsches Garten-Magazin.* Vols. 35-45. Col. pls. Illus. 8vo. GARDEN MANURES FOR NOVEMBER.

Although the supply of potash for the requirements of crops is largely produced in the soil by the natural decomposition of such mineral substances as felspar, hornblende, augite, etc., from which most of our clay soils are derived, and while, generally, potash is fairly abundant in these clay soils, they frequently respond in a remarkable degree to the application of a potassic fertiliser. Chemical analysis, for example, may show abundance of potash in a given soil amounting, perhaps, to several thousand pounds per acre in the first nine inches, and yet it may be impossible to grow a remunerative crop of Peas, Beans or roots on such land without the application of a potassic manure. On light, sandy soils and peats there is frequently a marked deficiency of potash in any form, and applications of potassic manures are essential to maintain fertility. Further, the absorption of potash by some crops takes place at a greater rate than that of the other two important elements, nitrogen and phosphorous, and if this is not restored to maintain the necessary balance, growth is materially affected through malnutrition.

The chief sources of potash are kainit, potash salts, sulphate and muriate of potash, of which kainit contains the least percentage of potash, but it is a valuable potassic fertiliser for autumn and winter application. It is an impure manure and contains a high percentage of salt, hence it is not suitable for all crops, but if applied in autumn or early winter any impurities which might be injurious to plant life will be dissipated before growth becomes active next year. It also contains an appreciable quantity of magnesia which, like potash, is an essential plant food and of especial benefit to root crops.

While sulphate of potash contains fifty per cent. of potash, kainit generally contains only from twelve to fifteen per cent., hence, to give an equivalent amount of potash, it would be necessary to give nearly four times the weight of kainit, but there is very little difference in the relative cost when unit values are compared. The choice is often one of convenience, for under some circumstances of cultivation advantages accrue from being able to apply a slow-acting fertiliser during the dormant season, and this applies particularly to the cultivation of fruits.

It is an interesting fact that, whereas an average grain crop removes considerably more nitrogen and phosphorous than potash from the soil, an average Apple crop removes more potash than nitrogen and phosphorous together. In the light of this fact it may well be asked if sufficient attention is usually given to the supply of potash in permanent fruit plantations. In areas under cultivation the constant moving of the surface soil helps to bring the natural supply in the soil into an available form, but in orchards under grass potash exhaustion is more likely to occur. Where grass orchards are grazed the potash removed by the stock is largely returned in the urine, but where a hay crop is taken further depletion of potash follows, and it becomes imperative to apply a potassic manure to maintain a balance of the elements. It is well-known that unsatisfactory results sometimes ensue from the use of nitrogenous manures, when the supply of potash is deficient, and it has also been noted that the partial failure of some phosphatic manures has been due to lack of a sufficient supply of readily available potash in the soil.

In cases where it is considered that potash is needed, autumn application of fertilisers supplying about 50 lbs. of potash per acre could be given every other year, and this amount could be provided by 4 cwts. per acre of twelve-and-a-half per cent. kainit, or 2½ cwts. per acre of twenty per cent. potash salts.

Cyanamide is a source of nitrogen, and one of the few slow-acting nitrogenous manures available for use during the present season. It is manufactured by a process of fixation of atmospheric nitrogen, which is caused to combine with calcium carbide at a very high temperature. Its action is influenced considerably by the physical condition of the soil, and it is probably due to this factor that it shows less regularity in results than sulphate of ammonia or nitrate of soda. It is best used fresh and if applied to dug or trenched ground which is to remain rough during the winter months, its thorough incorporation with the surface soil is assured when cultivating operations take place in the spring. It contains about nineteen per cent. of nitrogen in the form of calcium cyanamide, and up to sixty per cent of lime, more than half of which is free lime; it is, therefore, valuable as a means of maintaining the lime content of the soil, but should in no case be considered as a substitute for lime. The nitrogen is transformed by a series of changes into compounds that the plant can utilise, and finally ammonia and nitrate are produced by the aid of bacteria. It appears to give better results in the heavier, retentive soils than on the light ones, which may be due, to some extent, to the physical effect of the lime. *W. Auton.*

HOME CORRESPONDENCE.

Imperial Fruit Show.—The Imperial Fruit Show is being held at Birmingham, and from enquiries made, the authorities do not accept subscribers, neither do they sell tickets. Are they progressive? I usually subscribe to these local shows, and purchase tickets to give away to my friends, but in this case I am debarred from so doing, so shall not go. Also many of my friends will not receive tickets, therefore they will not go. I wanted to purchase some fruit trees, so these orders will go elsewhere. *J. A. Restall, Birmingham.*

Berberidopsis corallina.—I was most interested in the article by *L. B. C.* on Berberidopsis corallina in your issue for October 12, p. 284. It may interest your readers to know that we have here what I consider a very fine specimen, being twenty feet high and twelve feet in breadth, on a north wall; it flowers profusely and seems to revel in this position. I understand from one of the oldest employees here that it was planted nearly thirty years ago. *G. W. Hannaford, Carclew Gardens, Perran-ar-Worthal, Cornwall.*

Royal Horticultural Society and its Lecturers.—Judging from the attendance on October 23, the Royal Horticultural Society's Lectures are popular with Fellows. But whether that is so or not, the general arrangements would disgrace even a small local Society. There was no one in authority, indeed, no official or employee of any grade, in the lecture room until the hour to commence (three o'clock) arrived, when the Assistant Secretary came in, apparently to make sure that lecturer and chairman were present, and speedily disappeared. It may be (but this is merely an assumption of vanity) that Mr. Alexander and myself are so well known that we were, so to say, "taken as read." We have no personal complaint, nevertheless, such lack of courtesy is undignified on the part of the Council. Further, not so long ago, a very well known gentleman travelled hundreds of miles to deliver a lecture at the R.H.S. Hall; no one received him, and apparently no one cared a pin so long as he mounted the platform at the proper moment; a friend, finding him wandering around the hall, entertained him to lunch. It is asking very little of the Council to extend some courtesy to its lecturers, and to entertain those who make a long journey to give a lecture they have been invited to deliver. *Charles H. Curtis.*

Gentiana sino-ornata.—So much has been written in favour of Gentiana sino-ornata, which is, perhaps, the best of our late autumn alpine plants of recent introduction, that I refrain from writing much about it. Recently, however, I saw in a contemporary a query as to the cause of its failure in some gardens, and a reply to the effect that G. sino-ornata was subject to a disease. I am in correspondence with a goodly number of growers of this Gentian, both amateur and trade, and I have never heard of any disease affecting it until now. I should be glad to know if any of your readers have seen or heard of this disease, which is stated to be of a fungoid nature. G. sino-ornata is such a precious plant that anything affecting its well-being in our gardens is of more than usual importance. I may add that I have it in several places, and in all it is perfectly healthy and flowering admirably. *S. Arnott.*

Brunsvigia Josephinae.—Having read with much interest the article on the flowering of Brunsvigia Josephinae (*Gard. Chron.*, October 12, p. 282), it may be of interest to record that I received six bulbs of this plant from the Cape in 1926, and although, as your correspondent states of his, the foliage was healthy and strong, no flowers were produced in 1927, but one flowered last year, and five of the six gave very fine spikes this year. Having grown these bulbs before, my own experience is that they must become established, and in the season of rest they should be subjected to a hot, dry atmosphere—of 70° or more—to thoroughly ripen them. When starting them into growth, plenty of water should be given, and a genial atmosphere, with a temperature of from 60° to 65° maintained. I do not recommend stimulants, but give them plenty of room in a mixture of loam, peat and sand in equal parts. *G. W. Hannaford, Carclew Gardens, Perran-ar-Worthal, Cornwall.*

COLONIAL CORRESPONDENCE.

HIBISCUS ESCULENTUS.

I WAS very interested to read the article on The Gombo, by *A. M. W.*, on p. 154 of *The Gardeners' Chronicle*. This vegetable is largely cultivated in Malaya under the native name of Kachang Bendi. It is much appreciated by people of all nationalities, although Europeans consider it to be too mucilaginous; this, however, is not so noticeable if the fruits are cut into slices and fried in the same way as are Capsicums. The plant grows to a height of about six feet, and bears palmate leaves and erect, horn-like pods six to eight inches long. These are harvested while green, before they are ripe. They are usually either boiled whole or cut into slices and used in soups or salads.

In Malaya the plants are grown in the open, in rows three feet apart and two feet in the rows. Two seeds are placed in each hole, and after germination the strongest seedlings are selected and grown on. The first fruits may usually be gathered about ten weeks from seed sowing.

Although not often seen in England the fruits of this Hibiscus are well-known in many widely separated parts of the world. In America it is known as Okra, in Ceylon, Bandakka; while it is known to Europeans in this country as Lady's Fingers which, in my opinion, is not complimentary to the fair sex. The following is an extract from a paper issued by the United States Department of Agriculture on "The Uses of Okras (Kachang Bendi)." "The principal use of Okra is in soups and various culinary preparations in which meats form an important factor, as in the so-called gumbo soups, to which the young pods impart an excellent flavour besides giving a pleasant mucilaginous consistency. The young seeds are occasionally cooked in the same way as green Peas, and the young and tender pods are boiled and served as salad with French dressing. Both the stem and the mature pod contain a fibre which is employed in the manufacture of paper."

No copper, brass, or iron cooking utensil should be used when cooking Okra, as the pods are liable to become poisonous. All the preparations should be made in an earthenware or porcelain vessel. The mucilage is stated to consist of pectin and starch. An oil known in commerce as "Oil of Ben" is obtained from the seeds; it does not become rancid easily, and is, therefore, much esteemed.

ADANSONIA DIGITATA.

THIS remarkable tree, which is known as the Baobab or Monkey Bread Tree, is a member of the Natural Order Malvaceae. This Order includes some important economic plants, such as Cotton and Okra, and ornamental shrubs, including Abutilons and many varieties of of Hibiscus.

A. digitata is a native of tropical Africa, and has been introduced into many other tropical countries. It is reputed to be one of the longest-lived trees in the world. It does not grow to a great height, but the trunk often attains a diameter of thirty feet.

The fruit is a large-shelled, woody capsule borne on a long, pendulous stalk. Each capsule contains a number of cells which are filled with spongy pulp in which the seeds are embedded; this pulp is slightly acid and is often eaten, while the juice expressed from it possesses certain medicinal properties. The fibre from the inner bark is used for making ropes.

The seeds are stated to yield 63·3 per cent. of kernels, which contain 63·20 per cent. of a whitish, solid fat. *F. S. Banfield, F.L.S., Malaya.*

FOREIGN CORRESPONDENCE.

PHYSOSTEGIA VIRGINIANA VAR. VIVID.

WHETHER or not this Physostegia is grown in Great Britain I am unable to state, but it is fast becoming a popular garden plant on this side of the Atlantic. According to the firm of Wayside Gardens, Mentor, Ohio, it is a seedling of P. virginiana which originated in their extensive nurseries. It differs markedly from the parent plant in several important particulars. First, its flowering season is quite three weeks later, as it is at its best during late September and October. Then, it is much dwarfer in growth, never exceeding a height of two feet, yet the inflorescences are very much larger and of a much more attractive colour than in the type plant. The flowers are arranged rather densely in four ranks, in leafless, terminal, simple or panicled spikes. Each flower is one inch or slightly more in length; and half that in diameter across the mouth. They are of a bright rosy-pink hue, with just a slight suggestion of mauve but not sufficient to render the colour objectionable to those who abhor anything approaching magenta and similar tones. The simple spikes are four or five inches in length and resemble, in general appearance, a giant Heather, although naturally differing greatly in botanical details from the Ericaceae.

Physostegia v. var. Vivid is an easy plant to cultivate, revelling in a rich soil and open situation. It is of sturdy habit and, of course, is absolutely hardy. Propagation is readily and rapidly effected by means of division or by cuttings.

It is now listed by many nurserymen in the eastern United States and excites favourable comment whenever it is seen at the flower shows. Every indication is that its popularity will increase, for it is exceedingly useful for furnishing cut bloom late in the season, so well as for supplying colour in the border, while it may be used with good effect in certain positions in the rock garden. Unlike the greater number of the Labiates, the foliage of this plant possesses no noticeable odour, and in my experience it is a clean grower, free from attacks by disease or insect. *T. H. Everett, Pleasantville, New York, U.S.A.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

THE following awards were made by the N.C.S. Floral Committee at its meeting held at the R.H.S. Hall, on Monday, October 21:—

FIRST CLASS CERTIFICATE.

Mrs. W. Hall. II. 1*a.*—A large, exhibition, Japanese variety, with broad florets that incurve slightly at the tips; deep rosy mauve, silvery reverse. Shown by Mr. W. HALL Enton Hall Gardens, Witley.

Dazzle. IV. a.—A distinct and beautiful addition to the list of Pompon varieties. The shapely, crimson flowers are two-and-a-half to three inches in diameter, and borne freely in elegant sprays; we counted twenty blooms on one spray selected at random from many others staged in a large vase.

Mrs. Sarah Knight. II. 1*b.*—A flattish flower of deep reddish rose colour and with pointed florets. A useful decorative variety. These two last were shown by Mr. H. SHOESMITH, junr.

Lustre. I. 1.*a.*—An incurved variety, rather flat for exhibition purposes, but an excellent decorative sort; silvery mauve.

Red Cavell. II. 1.*a.*—A large-flowered sport from Edith Cavell and like it in all but colour; reddish chestnut with old gold reverse. [We believe the correct name of this sport is Mme. Gabrielle Thiaux (see p. 339).—EDS.]

These two last varieties were shown by Messrs. KEITH, LUXFORD AND CO.

Mrs. J. W. Stone. V. 1.*a.*—A very large and beautiful sport from the well-known single variety named Mrs. W. Smith. The flowers are of large size, good form, and fine substance; there are several rows of florets and the colour is clear primrose. Shown by Mr. A. ROBERTSON Abbey Road, St. John's Wood.

COMMENDATION.

Bountiful. II. 1.*c.*—A free-flowering variety, bearing small flowers in large sprays; five feet; deep rose-pink. Shown by Mr. H. SHOESMITH, junr.

SALISBURY GARDENERS'.

UNDER the presidency of the Hon. Louis Greville, the Society held its twenty-third annual meeting at the White Hart Hotel, Salisbury. Mr. Gullick, the Hon. Secretary, presented a most satisfactory Annual Report which reviewed the work of the year. The Treasurer's report showed a balance of 7s. 2d. on the year's working, but a total credit balance to the Society of £54 19s. 4d.

The Hon. Louis Greville was re-elected President; Mr. A. C. Jonas, Vice-President; Mr. S. W. Tucker, Chairman; Mr. P. Baglin, Hon. Treasurer; Mr. F. Gullick and Mr. C. J. Phelps, Hon. Secretaries; and Mr. A. Hammond, Librarian.

At the conclusion of the business, the Chairman presented Mr. Baglin, Mr. Gullick, Mr. Phelps and Mr. Tucker with gifts subscribed for by the members of the Society in recognition of their having each given twenty-one years' faithful service to the Society in their respective positions of Hon. Treasurer, Joint Secretaries and Chairman. Mr. Baglin was given a suitable inscribed set of bowling "woods." Mr. Gullick was asked to accept an Oak roll-top desk, also suitably inscribed. Mr. Phelps, a china tea service; and Mr. Tucker an inscribed silver cigarette case.

The Vice-President explained that these gentlemen had so long and faithfully served the Society in their respective capacities that the members felt the time had arrived when they should show their appreciation in some tangible way, and that occasion had been chosen for the presentations. He was only voicing the members' feelings when he said that he hoped they would appreciate the gifts, not for their intrinsic value, but as a token of the members' high esteem for the services they had rendered. He hoped they would live many years to enjoy the gifts.

After suitable acknowledgments from the recipients, a pleasant meeting closed with a vote of thanks to the Chairman.

CARDIFF GARDENERS'.

At the fortnightly meeting held at the Queen's Hotel, Cardiff, on October 15, Mr. W. H. Pryce presided. There was a large gathering of gardeners, and a number of ladies were present especially invited to hear a lecture on Dahlias, which was given by Mr. F. Treseder of the Cardiff Nurseries.

Commencing with the old Dahlia coccinea which came from Mexico, and of which he had a specimen on view, Mr. Treseder dealt with the history of the Dahlia, and referred to the several species. Later, he dealt chiefly with the Miniature Decorative varieties, better known as Charm Dahlias, and the dwarf Mignons, which are so useful for bedding purposes. Many of these he had in bloom, besides several excellent seedlings not as yet in the market. Mr. Treseder gave admirably full details regarding propagation, cultivation and the entire management of plants in all stages; he also discussed enemies and diseases.

Some splendid vases of cut flowers were staged, also fruits and Begonias, all of which were awarded prizes and points. A superb large vase of Dahlias was staged by the Chairman and this was the centre of admiration

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

Mr. Charles H. Curtis presided at the monthly meeting of this Society, held in the R.H.S. Hall, on Monday, October 14. Nine new members were elected. Four members withdrew a total of £148 2s. 10d. from their deposit accounts, and the sum of £30 12s. 3d. was paid to the nominee of one deceased member. The sick pay on the Ordinary side amounted to £70 10s. 5d., and on the State side to £76 8s. 7d., while maternity benefits amounted to £7.

The Trustees were empowered to invest a further £1,000. Grants amounting to £26 17s. 9d. were made to eight members for dental and optical treatment, and several other cases were considered.

THE IMPERIAL FRUIT SHOW.

The unusually gloomy interior of the Bingley Hall, Birmingham, presented a bright and animated appearance when the Ninth Imperial Fruit Show opened on October 25. The promoters of the exhibition are to be congratulated on the arrangements, and from the point of view of effectiveness the show was vastly superior to the one that was held some years ago in the same building.

As a spectacular display of home and empire grown fruits, so well as fruits products, the show was a great and successful effort; it also had many educational features of interest to fruit-growers, and the space in the hall was occupied in such a way that while there was no overcrowding, everything could be seen with ease and comfort. The boarding of the floor was a great improvement on the tan which covered it on the occasion of the last Birmingham Show, and it is doubtful whether any previous exhibition in the Bingley Hall has been set out in such a tasteful manner.

The purely competitive part of the show, however, seemed very small in comparison with other features, so small, in fact, as to appear insignificant to visitors after an inspection of the elaborate display made at considerable trouble and no small expense by the Empire Marketing Board.

While the spectacular side of the Imperial Fruit Show has developed and improved to a marked extent, as a competitive exhibition of British-grown fruits it will hardly bear comparison in extent with those held when, and for a few years after, the series was commenced.

The chief feature was the big classes of fifty standard boxes of culinary Apples, and a similar number of half-boxes of dessert Apples, open to British growers, with similar classes open to growers in the overseas Dominions. These classes, in which liberal prizes were offered, resulted in keen competition among commercial fruit-growers whose names have become familiar as regular prize-winners at Imperial Fruit Shows, and had it not been for these big classes the competitive display would have been very small indeed. Among the most successful exhibitors were Messrs. F. and M. Dixon, Tardebigge, Worcester, and other familiar names appearing on the prize cards in various classes were those of the Hollesden Bay Labour Colony, Paget Norbury; Messrs. Seabrook and Son, The Overbury Orchards Co., Mount, and the Reading University, the last-named having the honour of winning, with splendid boxes of Worcester Pearmain, the Murphy Cup for the finest lot of Apples in the show. The awards were made, as usual, by a panel of judges on a score-card system, certain points being given for the fruits and others for packing. The score-cards were afterwards displayed on the exhibits so that competitors could tell where they lost or gained, but the weak point in the method was displayed by the number of equal prizes awarded which could, and should, have been avoided.

The Apples shown in bushels and barrels, which used to be a big feature at Imperial Fruit Shows, occupied a comparatively small space in one of the galleries, and the prize-winners were in many cases the same as in the box classes. As a whole, the quality of the fruits was extremely good, particularly among the Cox's Orange Pippins, and the packing showed that our leading commercial growers have little now to learn from overseas competitors whose methods they have copied.

In addition to the truly wonderful display made under the auspices of the Empire Marketing Board, in which there were fresh and preserved fruits from all parts of the Empire, there were the usual demonstrations in grading and packing Apples, and the Research Stations at Long Ashton and East Malling combined forces in setting up an exhibit of a highly educational character.

The distributing and retail fruit traders were well represented by very tastefully arranged stands, and several nursery firms set up exhibits of fruits and young trees. The exhibition was opened officially by H.R.H. Prince George, but the time of the ceremony was altered at short notice for unavoidable reasons, and took place at midday on the 25th instead of in the afternoon, as announced on the invitation cards sent out.

NORTH OF ENGLAND HORTICULTURAL.

The Autumn Show, held by this Society at Harrogate a short time ago, was in every way a great success.

The awards to non-competitive exhibits were as follows :—

Large Gold Medals.—To Messrs. Dickson and Robinson, for Dahlias (also the Harrogate Corporation Cup); Messrs. Thomas Robinson, for Roses (also the Whitehead Cup); and the the Harrogate Corporation, for decorative plants.

Gold Medals.—To Messrs. Dobbie and Co., for Dahlias; Messrs. G. Gibson and Co., for a group of plants (also the Ashworth Cup); Messrs. Mansell and Hatcher, for Orchids (also the Ogden Cup); Messrs. S. McGredy and Son, for Roses; Messrs. Pennell and Sons, for a collection of fruits; Messrs. Kent and Brydon, Ltd., for a collection of vegetables; Messrs. C. Gregory, for Roses.

Large Silver-gilt Medals.—To Messrs. Backhouse Nurseries, Ltd., for a table rock garden; Messrs. Daniel Bros., Ltd., for fruits and Montbretias; and Messrs. W. and J. Brown, for Roses.

Silver-gilt Medals.—To Messrs. Bakers, Ltd., for herbaceous flowers; Messrs. Whitaker and Wilson, Collingham Bridge, for Gladioli; Messrs. Allwood Bros., for Carnations; and Messrs. F. E. Green, for examples of topiary work.

Large Silver Medals.—To Mr. W. Wells, junr., for Asters; Messrs. Harkness and Sons, for herbaceous flowers; Messrs. Hewitts, Ltd., for Delphiniums; and Messrs. R. V. Roger, for Roses and Apples.

Silver Medals.—To Mr. J. C. Schneider, Boston Spa, for rock plants; Mr. H. Dyson Walker, for Dahlias; The Bulb Farm, Wetherby, for Gladioli; Messrs. Kent and Brydon and Haigh, Ltd., for Asters; the Rev. C. Gallacher, Harrogate, for Begonias and Gloxinias; Messrs. W. H. Simpson and Sons, for Asters; Messrs. H. H. Maw and Son, for miscellaneous flowers; Mr. W. Kershaw, Saltaire, for herbaceous flowers; Mr. A. W. Whitelock, Harrogate, for Chrysanthemums; Messrs. C. H. Bloom and Sons, for a rock garden, etc.; Messrs. P. Gardner, for a table rockery; and Messrs. Wheatcroft Bros., for Roses.

Bronze Medals.—To Mr. J. E. Dalgleish, for Roses; and Messrs. Greenwood and Co., for hardy plants and fruits.

ROYAL HORTICULTURAL.

FOURTH AUTUMN SHOW.

(*Concluded from p.* 334.)

A wholly admirable group of stove and greenhouse plants was arranged by Messrs. L. R. Russell, Ltd., at the far end of the hall. Not only was there a large and varied collection of splendidly-grown plants, but their disposal was especially successful. Many particularly well-coloured Codiaeums (Crotons) and tropical Cordylines (Dracaenas) provided rich colouring, while at the back there were graceful Palms and tall specimens of broad-leaved, red-marked Acalypha Macafeeana, while many Pitcher Plants (Nepenthes) placed on pedestals along the foreground added to the value and attractions of the exhibit. The principal Nepenthes were N. Rafflesiana, N. Hookeriana, N. Henryana and N. Mastersiana purpurea. In addition, there were some very beautiful varieties of Begonia Rex, foliage Anthuriums and Allamandas. At either end of these gorgeous and fascinating tropical plants there were valuable and instructive groups of tropical and sub-tropical plants of economic value. These included luxuriant specimens of several species of Banana, of value either for their fruits and fibres, and well-grown plants which supply such necessities and luxuries as Pineapples, Coffee, Cocoa, Tea, Ginger, Pepper, Cinnamon, Cochineal, Vanilla, Cocaine, Teak Wood and Croton Oil.

A showy and effective group of greenhouse plants exhibited by the Duke of Wellington (gr. Mr. H. J. Beckingham), Ewhurst Park, Basingstoke, was composed of excellently-grown plants of Coleus Sunset and Celosia plumosa varieties, with many cut flowers of Nerine Bowdeni and Sternbergia lutea. Messrs. Blackmore and Langdon staged large, round baskets filled with plants of greenhouse Cyclamen and floriferous little Begonias of the semperflorens type, while Messrs. Wed. P. Eveleens and Zonen also showed plants of Cyclamen persicum varieties.

The several exhibits of Chrysanthemums were very attractive, and the quality of the blooms of the various types augured well for the success of the forthcoming show of the National Chrysanthemum Society in the same building. The large Japanese varieties were well shown by the King's Acre Nurseries, who had particularly good blooms of W. Renshaw, Daily Sketch, Mr. D. Slack, Mauretania, Mrs. R. C. Pulling and Edith Cavell.

An exceedingly attractive and well-arranged group of varieties especially valued for market sale was made by Mr. A. G. Vinten. The varieties Miss Eva Hudd, Mrs. Phil Page and Jean Pattison provided rich bright colour, while

Salmon Queen, Golden Wonder and Autumn Gold were also very attractive. Messrs. Keith Luxford and Co. showed many good decorative varieties, including Cranford Pink, Elsie Heady, J. Bannister and Pink Delight, and also had fine blooms of Mrs. W. J. Stone and several good Singles.

Late autumn Roses of considerable beauty were shown by Messrs. B. R. Cant and Sons, Messrs. Alex. Dickson and Sons, Messrs. Wheatcroft Bros., and Mr. George Prince. Their customary displays of excellent greenhouse Carnations were set up tastefully by Messrs. C. Engelmann, Ltd., Messrs. Allwood Bros., and Messrs. Stuart Low and Co. Sweet Violets were staged by Mr. G. Zambra and by Mr. J. J. Kettle, who also showed fruiting branches of autumn Raspberries.

Bunches of brilliant trusses of Zonal Pelargoniums in considerable variety were well set up by Mr. R. J. Case. His single varieties included Cheerful, deep rosy-cerise; Exquisite, rosy-pink; F. W. Penny, glowing scarlet; Janet Scott, deep rich orange; Mars, dark crimson; Patrick, cerise shaded with purple; and Staplegrove Beauty, deep rosy-salmon. Nearby, Mr. H. A. Brown had plants of such Fuchsias as fulgens, Coraline, parviflora and Thalia.

An interesting collection of well-grown Succulent plants was set out by Mr. T. M. Endean. He had large specimens of Pilocereus senilis, Echinocactus Wislizenii, E. Grusonii, E. recurvus and Mammillaria gigantea, with smaller plants of a great variety of these fascinating plants.

A large and effective group of Statice profusa superba and white Chrysanthemums and white Carnations was arranged by the Rolvenden Nurseries

Dahlias were staged in exceptionally fine quality by Mr. J. B. Riding, whose large exhibit would have been noteworthy even in the height of the season. Glowing colour was provided by the large stands of Titan, Brightness, Dazzle, Norah Bell, El Granada and other valuable sorts, while the Cactus varieties were well represented by Golden Sun, Golden Queen and E. Siebling. Messrs. Wm. Treseder, Ltd., also had a good collection and their chief sorts were Bishop of Llandaff, Dr. H. Spath, Pride of San Francisco, Vida and a good collection of Pompons. Messrs. J. Cheal and Sons set out Star Dahlias and the decorative miniature Paeony-flowered varieties with their collection of shrubs.

Hardy shrubs, more especially the species and varieties which bear luxuriant crops of ornamental fruits, were one of the chief features of the show. They occupied considerable space and most of the exhibits were exceedingly beautiful.

In the body of the hall a delightful group of very many ornamental shrubs was exhibited by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Hants. Along the centre, there were tall, graceful branches of Pyracantha Rogersiana flava, Hippophae rhamnoides, and Stranvaesia salicifolia arching over vases of Cydonia Maulei var. rosea, studded with yellow fruits, Lonicera Maackii, many species and hybrids of Berberis and a great variety of Pernettya mucronata, Crataegus Canbyi showing autumn colour both in its foliage and fruits, Berberis virescens carrying purple leaves and berries, Cotoneaster frigida var. fructu luteo and a bright and graceful hybrid of Cotoneaster Watererii were also very attractive.

On a large wall space the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, set out an enormous collection of branches of ornamental trees and shrubs from his famous garden. The large, yellow, Quince-like fruits of Cydonia japonica var. Wilsonii attracted a deal of attention. Among the many other valuable shrubs were Viburnum Opulus var. xanthocarpa bearing many pendulous bunches of shining yellow fruits; seedling Berberises with rich golden and orange-red leaves; Pyrus pinnatifida var. Gibbsii, with ample bunches of large, scarlet fruits; Spiraea media, with delicate rosy-purple foliage; Rhus typhina, with leaves of fiery scarlet colour; and Taxus cuspidata var. fructu luteo showing shining yellow fruits. There was also a tall bush of Pyrus Malus var. aldenhamensis in full flower. The normal late autumn-flowering shrubs were represented by bushy plants of various Heaths, and vases of Ceanothus Arnoldii, Ceanothus Féndlerii, Buddleias, Ligustrums, Fuchsia Thompsonii, Caryopteris Mastacanthus, Ulex europeaus var. strictus and several varieties of the hardy Hybiscus, Althaea frutex.

The Countess of Cawdor (gr. Mr. H. Windebank), Frensham Hall, Haslemere, had a neat collection of varieties of Pernettya mucronata, Cladastris scandens and Berberis asiaticus in fruit; while from Wisley were sent three Berberis seedlings, one of which bore many pendulous bunches of berries on long stems much like little bunches of oval, orange-scarlet Grapes.

Vivid autumn colour was shown on branches of Pyrus discolor, Berberis Thunbergii, Acer Ginnala and Ribes americanus in the exhibit of Messrs. J. Cheal and Sons, who also showed heavily fruited branches of the Snow Berry and Pernettya mucronata, with flowering sprays of various shrubby Veronicas. A colourful exhibit was also staged by Messrs. G. and A. Clark, who included many useful shrubs. Messrs. E. F. Fairbairn and Sons set up a good collection of late trusses of herbaceous Phloxes.

In an interesting and graceful exhibit, Mr Amos Perry showed Nerine Bowdeni and the superior variety major, Lavandula pectinatus, Lilium nepalense and a quantity of Anthemis tinctoria, Perry's variety.

SOCIÉTÉ BELGE DES CHRYSANTHÉMISTES.

The second exhibition of this Society was held in the Palais du Midi, Brussels, on October 26, 27 and 28. A good show was provided, and those competent to judge considered it to be a great improvement upon the initial exhibition of 1928.

The Juré consisted of Mr. Charles H. Curtis, President; Mr. H. de Lange (Holland), Secretary; M. Etienne Jouris, M. E. Nagels and M. Sils, with M. J. Simon as conductor.

As the exhibits in any one class were seldom arranged together, or even near each other, but disposed in the exhibition hall so as to secure the best general effect, it will be readily understood that judging occupied a considerable time and necessitated a great deal of walking about. It was, therefore, fortunate that in several of the fifty classes provided there was but one exhibitor. But to the ordinary duty of deciding which of certain exhibits are first, second or third, in order of merit, another is added at many continental shows—as on this occasion—where the prizes are supposed to be medals. This additional duty is that of determining the value of the "medal" awarded (where such value is not stated), and this is done in accordance with the merit of the exhibit. Thus a medal valued at 200 francs may be awarded, yet in another class, of similar extent, the award of a medal of the value of 150 francs, or possibly only 100 francs, may meet the case. Where the prizes are definitely set forth and valued in the schedule, all is straightforward once the exhibits are rounded up, but when it comes to appraising the exhibit and making the award accordingly, the business is often strongly suggestive of making "the punishment fit the crime."

However, all was finished in time for the Secretary, M. Roekens, to get all the prize cards in position, and for the judges to enjoy a *petit dejeuner* before the Japanese Ambassador to Brussels, M. Nagai, came to give the exhibition his blessing. His Excellency was keenly interested in the principal exhibits which were pointed out to him by M. Bols, the President; M. Moonens, Vice-President; M. Corbeel, Treasurer; and M. F. Roekens, the hard-working Secretary. His Excellency also chatted for some time with Mr. Curtis, who discussed several British-raised varieties with him, including the golden Viscount Chinda, named after the late Ambassador to London.

Conifers, Bay Trees and Palms were used as a background for large groupings at each end of the hall, and at one end a big Japanese gateway broke up the Conifer plantation, which was bordered with early-flowering Chrysanthemums in pots, while in the lawn in front, stepping stones led up to the gate itself.

The centre of the hall was set out to represent a rectangular pool of water, with an edging of small, white and purple Chrysanthemums and Ferns, within the curb, and three huge garden vases of large Chrysanthemum blooms—one of fifty flowers of Queen Mary—down the centre of the "water."

In the principal class, of national importance, the schedule required a dozen vases of flowers, five blooms of one variety in each vase. The first prize was the Society's Challenge Cup and Gold Medal. This handsome award was won by M. Odon Warland, a keen and wealthy amateur horticulturist, who resides at Uccle. We congratulate M. Warland and his gardener M. Baeck, upon their success in this and in many other classes, as they showed fine flowers of Majestic, Red Majestic, Queen Mary, Lady Findlay, Rose Day, Mr. T. Attwood, Mrs. Harold Wells, Paul l'Abbé, Viscount Chinda, R. C. Pulling and Mona Davis. The second prize was won by M. H. Van Loo, Chef de Service des Plantations de la Commune de Schaarbeek—a place just outside Brussels. In size and colour many of the flowers shown by M. O. Warland, would compare favourably with those shown in the principal British competitions, nevertheless, there is a great deal of levelling up to be done ere the British standard is reached.

An international character attaches to this exhibition inasmuch as one class for a dozen vases of flowers, five flowers of one variety in each vase, is open to all countries, and M. O. Warland has provided a large and handsome Challenge Cup as an attractive first prize, while the Society adds a Gold Medal. The Cup was won by Baron de Mevius (gr. M. Mertens), Chateau de Arthey, Rhisnes; the best varieties in this collection were Queen Mary, Viscount Chinda, Arnold Wells, P. Rivoire, R. C. Pulling, Majestic, Undaunted and Paul l'Abbé. Several members of the Society proposed to visit the National Chrysanthemum Society's show in 1930, to "spy out the land," and return with a determination to raise the Belgian standard of exhibition flowers to that of the British, in the hope that Belgium, Britain, and possibly France, may compete in this international class in 1931, but Mr. Curtis told them that very probably he might obtain enough first-class flowers to enable Britain to make a good fight for the Cup in 1930.

The principal prize-winners, other than those already mentioned, included M. Jean Espagne, M. Marin, M. Deschamps, M. Charlier, M. Van Loo, M. Nagels and M. Weyenberg.

The great majority of the large flowers were, however, British sorts, and it was interesting to find Mona Davis, Jas. Gibson, R. C. Pulling, Queen Mary, Majestic and Red Majestic exhibited so freely. Pillars of Almirante created fine splashes of colour, as did several huge vases, each containing fifty blooms, of R. C. Pulling, Viscount Chinda and Mr. T. Attwood. This last-named variety was particularly well-shown by M. Odon Warland, who had a ground group of fifty very fine examples of this soft pink and elegant variety.

Floral art was a distinct and beautiful feature in this show, and the several groups of bold designs contributed by members of the Union Professionelle des Fleuristes de Belgique, contained many very fine examples of the use of big Japanese blooms in the decoration of large tables, hall corners, huge specimen vases, baskets, etc. Similar contributions from a few of the leading London florists would prove a great attraction at a London show.

Dwarf pot plants were shown well and extensively, most of the exhibitors in this section showing the popular white Blanche de Poitevine; some of the plants, about fifteen inches tall, carried from ten to twenty flowers, but those carrying the smaller number produced the finest flowers. About eight such groups were arranged on the floor in different parts of the hall, and as each group contained fifty plants, the whole series filled a considerable space. One small-flowered variety that appeared fairly popular is named Purpurine, and it is well named, but the colour is not a shade that would find much favour in Britain. We understand, however, that it is grown somewhat extensively in view of the immense demand for flowers to be placed on graves on November 1—All Saints' Day.

Novelties were neither numerous nor particularly good, and only one was selected by the judges for consideration. This was named Lutéce, and it was awarded 30 out of 35 points for colour (soft rose-pink, paler in the centre) 15 out of 20 for "grandeur," 15 out of 15 for form, 7 out of 10 for doubleness, and 15 out of 20 for foliage; total, 82 out of a possible 100 points. It received a Certificate of the second class, as 90 points or over are needed to receive a First Class Certificate.

BRITISH CARNATION.

The following new Perpetual-flowering Carnations have been registered with this Society:—

Gladys.—Seedling, salmon-rose, fragrance fair, habit and stem good. Madge.—Seedling, orange, flaked bright pink, slight scent, habit and stem good, but rather slow grower. Nina.—Seedling, heliotrope (Mikado colour), fragrance fair, good stem and very free habit of growth, Registered by Messrs. C. Engelmann, Ltd., Saffron Walden.

Isobel Hamilton.—Seedling, rich, light pink slightly scented, stiff stem, free habit of growth Registered by Messrs. Walter Hemus, Ltd., Hanworth, Middlesex.

Sonny Boy.—Seedling, cerise, habit and stem extra good. Nada.—Seedling, salmon-pink, habit and stem good. Registered by Messrs. A. F. Dutton, Ltd., The Nurseries, Iver, Buckinghamshire.

Joan.—Seedling, yellow, habit and stem good, parentage from Maine Sunshine. Registered by Messrs. H. T. Mason, Ltd., Hampton Heath.

Lushill Scarlet.—Seedling, scarlet nearest colour, *i.e.* Brilliant or Aviator; exceptionally robust in habit, flowers strongly fragrant. Registered by Mr. Cecil Smith, The Gardens, Lushill, Highworth.

R. A. Nicholson.—Seedling, scarlet, near in colour to Spectrum. Ann Horton.—Seedling, white, pencilled carmine. Registered by Messrs. Stuart Low and Co., Bush Hill Park, Enfield.

READING GARDENERS'.

There was a very large attendance of members at the fortnightly meeting held in the Abbey Hall, on Monday evening, October 21, and presided over by the President, Mr. Frank E. Moring. Splendid specimens of Onions, Carrots and Celery were staged for competition, and a fine collection of Apples and Pears was exhibited in the non-competitive section. The competitions arranged for the evening and the results were as follows:—For six Onions (eight entries), first, Mr. W. Turnham, Greenlands Gardens, Henley-on-Thames; second, Mr. H. Tuffin, Iris Court Gardens, Pangbourne, and third, Mr. A. W. Gower, Calcot Grange Gardens, Reading. Six Carrots (eight entries), first, Mr. W. Turnham; second, Mr. A. Manley, Highfield Gardens, Heckfield; and third, Mr. H. Tuffin. Three Celery (five entries), first, Mr. E. Blackwell, Foxhill Gardens, Reading; second, Mr. A. W. Gower; and third, Mr. W. Turnham.

In the non-competitive section, Mr. A. Manley received a First Class Certificate for a collection of Apples and Pears, and also an Award of Merit for three well-grown Chrysanthemums. Roses and Marigolds were shown by Mr. F. G. Rabbetts, Bulmersche Court Gardens, Earley, and an interesting exhibit of Savoys by Mr. E. A. Beaumont, The Lodge, Copse Hall, Earley, consisting of a specimen lifted from the ordinary soil which was infested with club-root, and another which had been planted in cinders, and which was free from this devastating disease.

The Lecturer was Mr. H. H. Cook, Reading University Horticultural Department, and his subject was "The Forcing of Salads and early Vegetables." In his opening remarks he said that in his opinion there was no other subject that required more skill, care and forethought as the forcing of salads and vegetables. Mr. Cook went on to state that his subject was such a broad one that he could only briefly touch upon the many subjects that were suitable for the purpose. Cultural instructions were given for forcing Rhubarb, Seakale, Asparagus, dwarf Beans, Marrows, Potatos, Turnips, Carrots, Tomatos, Cucumbers, Lettuces, Endive, Chicory, Radishes, Mint and Parsley, and also the best places and positions in which they should be forced—in the Mushroom-house, greenhouse, frames, etc.

An excellent discussion followed, at the close of which a very sincere vote of thanks was tendered to Mr. Cook for a lecture that contained so much practical and valuable information.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

At a largely attended meeting of the members of the above Society, presided over by Mr. Isaac Fleming, Director of Parks, Paisley, Mr. William McCarrell, Deanston House Gardens, delivered a lecture on "Insect and Fungus Pests of the Garden." He discussed in detail the enemies of greenhouse subjects, such as mealy bug on vines; a trouble which caused Grapes to turn black, wither and show white spots on the leaves; mildew, shanking and red spider; shot-hole fungus on Peach trees; rust, white fly and black spot on Tomatos. Perpetual Carnations, he observed, gave him more trouble than any other occupant of the cool greenhouse. For more than twenty years he had always red spider on the plants and rust more or less. The presence of the fungus known as Fairy Ring was mainly due to the improper use of the watering can and doubtful environment, while rust on Cyclamen and Begonias of the Gloire de Lorraine type had its origin in over-heating and dry surroundings. The formidable host of troubles affecting Roses next claimed attention, and subsequently he dealt with the common pests of Brassicas; Carrot and Onion flies, Celery rust, blight and scab of Potatos, and the diseases and pests of fruit trees and bushes in general.

A protracted discussion followed, and at the close, Mr. McCarrell was accorded a hearty vote of thanks.

Obituary.

Mr. David Ewing.—His many old friends, scattered over a wide radius, will learn with regret of the death of Mr. David Ewing, who for over half-a-century was head forester on the Strichen Estates, Aberdeenshire. Blessed with an exceptionally healthy life, the end came very suddenly, at his residence, The Lodge, Strichen House. Fifty-five years ago, Mr. Ewing was appointed to the post which he continued to hold to the utmost satisfaction of his employers until a year or two ago, when the Strichen Estates, like so many more in the land, were broken up, and he went into retirement. He was known and highly esteemed around Strichen House and district by two generations, and the funeral at Strichen Churchyard was very largely attended. Mr. Ewing took no part in public affairs, but devoted himself whole-heartedly to his duties, and his fine record of service indicates how well and faithfully these were carried out. In June last he and Mrs. Ewing celebrated very quietly their golden wedding. He is survived by Mrs. Ewing, two sons and four daughters. The sons occupy highly responsible positions in London and India, and the daughters are all married.

ANSWERS TO CORRESPONDENTS.

Begonias Unhealthy.—*G. P.*—The Begonia leaves show no sign of having been attacked by any fungus disease, the only fungus obtained in culture being a saprophytic species. It would be advisable to refrain from overhead watering and to aim at keeping the house less humid than heretofore. The matter is a cultural rather than a pathogenic one.

Carrots Decaying in Store.—*E. C.* There would appear to be something in the ashes which is detrimental to the Carrots. We suggest you clean the roots well and then store them in sand.

Codiaeum Leaves infested with Scale. *W. G. B.* Your Codiaeums (Crotons) are badly infested with freshly emerged nymphs of the brown scale, Lecanium hesperidum. Both surfaces of the leaves should be sponged with a one per cent. solution of Volck. The cause of the dying back and brown spotting of the foliage is due to some error in cultivation, such as the amount of water received at the roots, and overhead syringing during the cooler and cloudier weather recently experienced. Careful attention must be given to the water requirements of these plants in order to preserve a correct balance between roots and leaves.

Chrysanthemum Leaf Eelworm.—*G. E. W.* The foliage of your Chrysanthemums is heavily infected with the Chrysanthemum leaf eelworm, Aphelenchus ritzembosi. Destroy all plants which show the symptoms of attack, which are brown areas in the younger leaves and dried up foliage at the base of the plant. The soil in which the plants are growing must be steam-sterilised in order to destroy the eelworms therein. An article on this pest appeared in *The Gardeners' Chronicle* of June 11, 1927, p. 415.

Names of Fruits.—*E. T.* Beurré Hardy.

Names of Plants.—*H. E.* 1, Eccremocarpus scaber; 2, send when in flower; 3, Hoya species, send in flower; 4, Mesembryanthemum crystallinum var. variegatum; 5, Nidularium fulgens.—*A. J. D.* 1, Centaurea Cineraria; 2, Cineraria maritima.—*J. L. W.* Ceratostigma plumbaginiodes.—*C. B.* 1, probably Saxifraga ligulata; 2, Phlox subulata variety; 3, probably Sedum multiceps; 4, Hieracium aurantiacum; 5, Sedum spathulifolium.—*H. L.* 1, Pyracantha Rogersiana; 2, Polygonum Baldschuanicum; 3, Senecio Veitchianum; 4, Hypericum patulum var.; 5, Viburnum Tinus; 6, Polygonum amplexicaule; 7, Statice latifolia; 8, Senecio Greyii.—*G. W. L.* Zauschneria californica.

Peach and Vine Roots Unhealthy.—*J. R.* While some of the roots of the Peach and vine are very unhealthy and covered with the mycelium of a saprophytic fungus, others are dead. It would appear that the trouble arises from poorly drained borders in which the soil is sour. The borders should be entirely renovated during the coming winter. Examine and rectify any defects in the drainage system of the house and refill the borders with a compost consisting of fresh turfy loam, mortar rubble, charcoal, wood-ash and half-inch bones. The sole addition of lime is an inadequate measure.

Seeds of Sagina procumbens.—*L. H.* We suggest you apply to Messrs. Thompson and Morgan, Ipswich.

Vines Unhealthy.—*H. N.* There is no sign of disease on the laterals and foliage of the Muscat vines. Scorch is undoubtedly the trouble and this is usually due to lack of shade. The complete renovation of the border with adequate drainage and early shading of the vines in early spring, should result in the elimination of the trouble.

MARKETS.

COVENT GARDEN, Tuesday, October 29, 1929.

WE cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—General requirements have shown a slight improvement during the past week, but with the exception of Lilium longiflorum and Arums (Richardias) prices have shown little change. The former reached the highest price for some considerable time, but this morning prices were a trifle easier. Among Chrysanthemums, Jean Patterson is the latest arrival in bronze blooms; white incurved blooms are now on sale, and the single varieties are becoming more popular. The disbudded blooms in pink, yellow, red and bronze are exceptionally fine in quality, especially of such varieties as Mary Edwards, Mrs. Edwards and Donald Edwards, also single Anemones and Violets from Cornwall and Devonshire are now arriving in excellent condition, and also small consignments of Forget-me-Nots and Marigolds. Some scarlet and pink Nerines from Guernsey are very fine.

REMARKS.—There is just a shade more activity in the market as compared with a week ago. An increasing volume of produce is arriving from abroad—Apples from the North American continent; Pears from California, central Europe and France; and Oranges from South Africa and Spain. Conditions in the English Apple market show a slight improvement after a rather quiet period. There is a slight shortage of really good cookers with the result that first-class Bramley's Seedling are making fairly good prices. Dessert Apples are also selling better, if good, but there is still a good deal of second-grade produce available which is difficult to clear at even poor prices. In the hothouse Grape section there is practically no change, the best English Grapes maintaining good prices, but other grades feel the competition of imported produce. The few good Peaches and Melons available continue to sell well. Tomatos are fairly plentiful, but there is not a large proportion of best samples available. Tomatos from the Canaries are in heavy supply and selling at reasonable prices. Cucumbers are selling fairly well and maintaining satisfactory prices. Hothouse Beans have recovered somewhat from the recent period of low prices and should now do well until the end of their season. Mushrooms continue to meet a steady trade, the quantities of field Mushrooms arriving being on a smaller scale. In the general vegetable market the enquiry for good Brussels Sprouts continues firm, and the trade all round is better. The salad section is also steady, with supplies just equal to the demand at present prices. Some Beans are now available from Madeira, and weekly arrivals will continue throughout the winter. In the Potato market supplies are in excess of demand, but quotations for the best sorts remain steady.

GLASGOW.

The cut flower market continued active last week when buyers were again attracted by the low prices of Chrysanthemums. Large quantities of blooms were provided by English and Scotch growers, and disbudded varieties failed to maintain the values of the previous week. Pink Consol made top prices, which ranged from 1s. 6d. to 1s. 9d for 6's; while other sorts received the following quotations:—Bronze Consol, 1s. 3d. to 1s. 6d.; La Pactole and Cranford Yellow, 1s. to 1s. 6d.; Rose Maid, Debutante, White Thorpe and Holicot Yellow and Bronze, 1s. to 1s. 3d.; Almirante and Sanctity, 8d. to 1s. 3d.; and Dolores, 8d. to 1s. Sprays fluctuated between 2d. and 6d. per bunch. Richardias advanced sharply and at 5s. to 8s. per bunch represent an increase of one hundred per cent. on the week. Carnations of all colours sold at from 2s. to 3s. 6d. per dozen; pink Roses, 2s. to 3s. 6d.; yellow, 1s. 6d. to 2s. 6d.; red, 1s. to 2s.; Lily-of-the-Valley, small, 6d. to 1s. per bunch; large, 2s. to 2s. 6d.; Michaelmas Daisies, 3d. to 6d.; Calendula, 2d.; Dahlias, 3d. and 4d.; Smilax, 1s. to 1s. 9d.; Asparagus, 3d. to 1s. 3d.; trails, 1s. 6d. to 2s. 6d.

In the fruit market sales of Apples were slow owing to the high prices resulting from the scarcity following poor crops in certain districts of Canada and the United States. McIntosh Red ranged from 15s. to 18s. per case; Jonathan, 14s. to 17s. 6d.; Grimes Golden, 14s. to 15s.; King of the Pippins, 25s. to 30s. per barrel; Wealthy, 28s. to 36s.; and York Imperial, 25s. to 27s. 6d. Doyenné du Comice Pears made 25s. to 27s. per case; Winter Nelis, 24s. to 26s. and Beurré Hardy, 13s. 6d. per half-case. South African Oranges sold at 20s. for 176's; Grape Fruits, Porta Rica 35s. per case; Blue Gorse, 40s. Californian Plums 11s. to 12s. per tray; Damsons and Blackberries, 4d to 5d. per lb.; Grapes, Black Hamburgh, 2s. per lb.; Alicante, 2s. 6d.; and Gros Colmar, 3s. 6d.

Vegetable prices were steady. Tomatos realised 7d. to 8d. per lb.; Beans, 8d. to 9d.; Mushrooms, 2s.; Cucumbers, 3s. to 5s. per dozen; Cauliflowers, 4s. to 6s.; Lettuces, 1s. 6d.; Leeks, 6d. per bundle; and Brussels Sprouts, 5s. per half-pot (20 lbs.).

GARDENING APPOINTMENT.

Mr. E. Miles, for the past eighteen years gardener to Captain the Rt. Hon. E. A. FITZROY, M.P., as gardener to the Hon. GEOFFREY HOWARD, Castle Howard, Welburn, Yorks. (Thanks for 2s. for R.G.O.F. Box.—EDS.)

CATALOGUES RECEIVED.

DIXONS, YORKSHIRE SEED ESTABLISHMENT, Hull.—Fruit Trees, Roses, Ornamental Trees and Shrubs, Herbaceous Plants, etc.

CHAPLIN BROS., LTD., Waltham Cross, Hertfordshire.—Roses, Fruit Trees, Ornamental Trees and Shrubs, Hardy Herbaceous Plants, etc.; Delphiniums.

WM. WATSON AND SONS, LTD., Killiney, Co. Dublin.—Flowering and Ornamental Shrubs, Conifers, Climbing and Wall Shrubs, etc.

WATKINS AND SIMPSON, LTD., Drury Lane, W.C.2.—Seeds of Flower and Vegetable Novelties.

AMOS PERRY, Hardy Plant Farm, Enfield.—Alpines, Perennials, Ferns and Bulbs.

MCHATTIE AND CO., Chester.—Roses, Fruit Trees, Ornamental Trees and Shrubs, etc.

W. WELLS, Junr., Merstham.—Hardy Alpine and Herbaceous Plants.

WM. CUTBUSH AND SON, LTD., Barnet.—Michaelmas Daisies; Roses.

THE LATEST TRADE MARKS.

This list of Trade Marks, of interest to readers, has been selected from the Official *Trade Marks Journal*, and is published by permission of the Controller of H.M. Stationery Office.

NEUTRAMMONKA.

Delphiniums at The Raft.

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 45·3°.

Actual Temperature—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, November 6, 10 a.m. (Greenwich time). Bar. 29·7. Temp. 50°. Weather, Raining.

R.H.S. Autumn Show.

We wonder how many of our readers who visited the Autumn Shows held by the Royal Horticultural Society are satisfied with the new arrangements. Many have expressed their views verbally, but so far we have seen few of these views in writing or in type. There is, however, a largely held opinion in favour of one big Autumn Show held in a spacious building like Olympia or Holland Park Hall, because it affords a far better opportunity of demonstrating the beauty of autumn flowers and foliage than several sectional shows held in a smaller building or buildings. The Council of the Royal Horticultural Society is, however, in a rather difficult position with regard to a big Autumn Show. We believe such an exhibition has invariably resulted in financial loss, although this need not be a serious consideration, for the Society has now many thousands of Fellows to cater for and their annual subscriptions must be regarded as prepayment for horticultural services and entertainments, and educational facilities. We doubt whether any fortnightly meeting "pays," but such meetings are, of course, the very life of the Society. Apart from any question of financial loss from a big Autumn Show held in a hall that has to be leased for the occasion, the Council has now two halls to maintain and, not unnaturally, desires to make full use of them, by splitting up or sectionising the Autumn Show and holding several exhibitions at brief intervals, instead of the one we have become accustomed to. Gardeners are conservative people and do not like to feel they have lost a great Autumn Show, even although given at least three others of smaller dimensions in its place. Probably one of the principal grievances is the absence of direct communication between the old hall at Vincent Square and the new one in Greycoat Street, Westminster. Nevertheless, although we would all prefer the whole show under the one roof, in fairness to the Council we must not overlook the fact that the general body of Fellows agreed to the construction of the new hall, minus a direct communication with the old one. The Council has done its best in regard to an Autumn Show (held in parts), and a very good best it has been. There are, however, one or two other grievances of sufficient importance to be mentioned. The Orchid enthusiasts have felt that their opportunities for business and display were severely curtailed by the sectional autumn displays, from which they were, for the most part, excluded; their complaint is worthy of consideration, although as they had one show—and a glorious show it was—practically all to themselves, they cannot claim to have been treated cavalierly. But there are other folk to whom little consideration appears to have been given. We refer to the gardeners, so many of whom have visited the great Autumn Show for educational purposes and to meet old friends. These could find the time and incur the expense for one show, but cannot afford the time or the money to visit three shows. To wealthy amateurs, and even a gardener living near London, this may appear to be a small grievance, but we can assure them it is not—and the argument that long distance Fellows and gardeners may choose to visit the sectional Autumn Show which most concerns them, is a very poor one, and also a trifle mean. We vote for one big Autumn Show in one big hall—and the Society can well afford it.

Our Supplement Plate.—Delphiniums are now to be had in such a wide and delightful range of colours that a border composed entirely of these, such as that portrayed in the Supplement Plate we have pleasure in presenting with this issue, presents a very impressive display when in full bloom. Mr. H. Walkden, in whose garden at The Raft, Derbyshire Road, Sale, this border is a special feature, informs us that the well-known varieties Belladonna semi-plena, Persimmon and Lamartine are used for the front rows, with Musis Sacrum, pale blue, and its white sport Walkden's White, directly behind them. For the intermediate rows the tall varieties have proved most useful, being replanted each year to keep them dwarf. The remaining space is planted with seedlings and various named sorts, which include Legionnaire, semi-double, bright blue; Statuaire Rude, large, double, pale mauve; Firmament, large, semi-double, dark blue and violet; Rene Gilbert, semi-double, bright blue; and Henri Moisson, semi-double, dark violet with brown centre.

Holme Lacy Estate.—A lady, who wishes to remain anonymous, has made a free gift of the beautiful estate of Holme Lacy to the county of Hereford, a condition being that the mansion is not to be destroyed or sold without first consulting and securing the consent of the donor. The Holme Lacy estate, which is situated about five miles from the city of Hereford and includes some finely wooded and rich meadow land, covers an area of three-hundred-and-forty acres. The River Wye passes through it, and lovely views of the Wye Valley can be obtained from it, while the mansion is regarded as the largest and most magnificent of the historical seats of Herefordshire.

Drought in the Arnold Arboretum.—The phenomenal drought which Massachusetts, in common with other states on the American Continent, has endured, will long be remembered for it caused grave anxiety among all who garden. In late June the Arnold Arboretum enjoyed one good rainfall, but not another worth mentioning until October 2. For fully two months supplying water to suffering trees and shrubs was the principal work engaged upon. Fortunately, there was no great heat, but at the height of the drought it appeared as though many plants must die. Thanks to the water stored from the heavy rains of spring, the trees suffered but little, and as autumn arrived a general freshening among all woody plants was noticeable; it is now difficult to realise that extreme drought has been experienced. The power of resuscitation enjoyed by plants is, indeed, marvellous.

Gladiolus Blackwellii.—The Gladiolus which received an Award of Merit on October 23, when shown by Mr. Collingwood Ingram as Gladiolus sp. (see p. 334), has now been identified by Dr. O. Stapf as Gladiolus Blackwellii, L. Bolus.

British Empire Trade Exhibition, Buenos Aires, 1931.—Official notice has now been given to the management of the great British Empire Trade Exhibition to be held in Buenos Aires in 1931, that His Majesty's Government has recognised the importance of the occasion and decided to participate on a suitable scale. For this purpose the Government exhibits will be housed in one of the finest buildings in the extensive exhibition grounds, which have been so generously lent by the Argentine Rural Society. The Government exhibits, besides illustrating the contributions of the British people to the world's progress, will show much of the development of our British Colonies and Protectorates. The Dominion of Canada has already reserved another building of 40,000 square feet, thus demonstrating the increasing interest taken by the Canadian Government and Canadian manufacturers in South American trade.

Horticultural Club Lectures. — Mr. F. Kingdon Ward has (provisionally) consented to lecture before the Horticultural Club, at St. Ermin's Hotel, Westminster, on December 10, when he will give an account of his recent plant collecting expedition in Asia. Mr. H. Cowley will give a lecture on his recent trip to the Alps, at the meeting to be held on January 14, 1930.

Mr. Alex. S. Galt.—We learn with very deep regret that Mr. Alex. S. Galt, so long associated with the horticultural work carried out under the Department of Agriculture, Leeds University, has been so seriously indisposed of late that he has felt compelled to tender his resignation to the Senate. His resignation has been accepted, and the Senate has made arrangements for Mr. Galt's retirement in March next. Old Kewites and many other friends will hope that after a period of rest, Mr. Galt may be restored to full health and wonted vigour.

Royal Horticultural Society of Aberdeen.—The Annual Report of the Directors of this Society, which is to be submitted to the Annual Meeting of the members on the 9th instant, states that owing to the very unfavourable weather which prevailed during the second and third days, the annual show held on August 15, 16 and 17, in Hazlehead Public Park, Aberdeen, resulted in a small deficit. The income for the year amounted to £648, while the expenditure was £651. The balance to the credit of the Society now amounts to £471 10s., irrespective of £320 of legacies held for specific purposes. The directors record with sincere regret the death of one of the Honorary Vice-Presidents, Mr. A. Emslie Benzie, of Morkeu, who took a keen interest in the affairs of the Society, and was a generous contributor to the funds. Seven of the directors retire at this time. The directors make an appeal to their fellow members to help them in their efforts to increase the membership, and so add to the usefulness of the Society.

New Park for Chesterfield.—The Chesterfield Corporation has purchased fifteen-and-a-half acres of land in the west end of the borough;

this is to be laid out as playing fields at a cost of £4,500, and will be known as the Somersall Playing Fields. The Corporation is also about to spend £10,000 on improving existing recreation grounds in the borough. The Parks Committee has also taken over the Goldwell Hill gardens and glass, to be used as a Corporation nursery, and two new glasshouses are to be erected at Queen's Park.

Potato Arran Banner.—Note is made in *The Gardeners' Chronicle* of November 2 (p. 338) of the fine results obtained by Mr. William Gardner, Roddinglaw, Gogar, Midlothian, with Potato Arran Banner showing a yield of 19 tons 8 cwts. per acre. Mr. R. Rogie, Easter Anguston, Culter, some eight miles from Aberdeen, has gone one better. Last year he planted one specimen of this variety, retaining the whole of the produce of the stem for planting this year. The "seed" thus conserved enabled Mr. Rogie this year to plant an area of fourteen yards in four drills. From this he has obtained a yield of 3¾ cwts., which is equal to 20¼ tons to the acre. The crop is remarkably good in quality, with few small and very few abnormally large tubers. In Fifeshire, too, some very good results are reported from this variety. All over Scotland the Potato crop has been eminently successful this season, but there is a fly in the ointment—the prices growers are obtaining are nothing short of a scandal. Between the grower and the consumer the dice is heavily loaded against the former. Many growers are making personal calls on urban consumers for orders, and it is pleasing to note this elimination of the middle-man is giving highly satisfactory results.

"The Journal of Forestry."—The quarterly issue of the *Journal of Forestry* (No. 4, Vol. XXIII, October, 1929), issued by the Royal English Arboricultural Society, contains much of interest to foresters and students of silviculture. "The Choice of Species" is the subject of the Editorial note; while original articles included are: "Some Impressions of South African Forestry," by Mr. C. P. Ackers; "Rough Hills Experimental Plots, Royal Agricultural College, Cirencester," by Mr. A. D. C. Le Seur; and "Trees suitable for Street Planting: Their Maintenance as Required in Large Cities and Industrial Centres," by Mr. J. Smith. Mr. W. Dallimore contributes notes on the International Congress of Forestry Experimental Stations, held in the Forestry College at Stockholm from July 21 to July 28 of the present year. The latter portion of the *Journal* is devoted to Official Information, and reports on the Annual Meeting, the Tree-felling Competition, the annual excursions of the Northern, East Anglian and South-Eastern Divisions, and of various forestry exhibitions held this year. An index to Volume XXIII is issued with this publication.

Meliosma myriantha.—Just after our issue of November 2 had gone to press, we received several twiggy growths of Meliosma myriantha from Mr. J. Comber, Nymans Gardens, Haywards Heath. The ovate-lanceolate leaves were gorgeously coloured in gold, orange and scarlet, while the several panicles of fruits were added attractions. On p. 348, Mr. Osborn refers to the flowers of Meliosma as small, yellowish-white and fragrant. In *Trees and Shrubs Hardy in the British Isles*, Mr. W. J. Bean refers to the fruits of this species as "crowded in a broad panicle, each about the size of a peppercorn, black." The fruits sent by Mr. Comber were of peppercorn size, but not crowded, and their colour was from pinkish-cream to coral-red. Meliosma myriantha is evidently a fine subject for the provision of brilliant autumn colour in the warmer parts of the country.

Harrogate Agricultural Show, 1930.—The Harrogate Agricultural Show, of which H.R.H. Princess Mary Countess of Harewood, is Patron, has grown rapidly in importance in recent years, and next year's exhibition has been fixed for Friday and Saturday, August 8 and 9. This year no show was held on account of the visit of the Royal Agricultural Society, but it is intended to re-establish the show in all sections, including the usual agricultural show, the poultry section, dog show and especially the horticultural section which was such a successful feature in 1928. The farm competition is to be continued, and included in the attractions will be the parades, horse leaping, sheep dog trials and probably military displays. When the last show was held the entries reached 4,600, and it is hoped this figure will be maintained, or increased, in 1930.

Mr. W. Petty.—Comparatively few men commence their horticultural careers in the garden where, in later life, they become head gardener. Mr. Petty is one of the few. He began his gardening life in the gardens at Melchet Court, then the seat of the late Lady Louisa Ashburton, under Mr. G. Hall. Here he was employed in all departments, and obtained sufficient experience there to fit him for the position of foreman to H.I.H. the late Empress Eugenie, at Farnborough Hill. In this latter position, Mr. Petty had charge of the floral decorations and was thus brought into contact with many members of foreign royal families.

MR. W. PETTY.

His next appointment was that of general foreman under Mr. A. R. Searle, at the Marquis of Northampton's garden at Castle Ashby. In 1913 he returned to Melchet Court, as foreman, but during the war he served on the western front, and after the armistice proceeded to Germany with the Army of Occupation, where he remained for eight months. Mr. Petty regards that eight months as one of the best educational periods he experienced. He returned to Melchet Court in 1919, when he resumed his position as foreman, and continued as such until in 1925 he was appointed to the full charge of Lord and Lady Melchett's gardens. Since 1925, many alterations have been made in the gardens and grounds, and in his work Mr. Petty has received the heartiest encouragement from his employers, both of whom are keen gardeners. There is now a good collection of Orchids at Melchet Court. Carnations and Chrysanthemums are made special features, and with both these subjects Mr. Petty has proved a skilful cultivator and successful exhibitor, while he has also been the raiser of several excellent perpetual-flowering Carnations.

Proposed Works in the London Parks.—In a written reply to Sir Newton Moore, who asked, in Parliament, "whether, in view of the concern expressed by residents in the neighbourhood of Owens Pond, Richmond Park, and others, in connection with certain operations in progress which it is alleged will interfere with the natural beauties of the park, he will give instructions for the contemplated work to be suspended pending representations being made to him," Mr. Lansbury states: "Judging by representations which have been made to me, there appears to be considerable misapprehension as to what is proposed. All that is being done at the moment is to clean out the pond. The bottom will not be cemented, nor will any permanent buildings be erected. It is proposed to have on the pond paddle-boats, such as gave enjoyment to some 40,000 children in Bushy Park last summer, and it is hoped to reserve an arm of the pond for the sailing of toy boats. With a view to preventing further misunderstandings, I am circulating in the Official Report, a list of all the proposed works in the Royal Parks towards which money has been subscribed." The list circulated is as follows:—Shelters: Greenwich Park, Kensington Gardens, Richmond Park, Bushy Park and Primrose Hill; Boating Ponds: Greenwich Park, Regent's Park and Richmond Park; Sandpits: Kensington Gardens, Richmond Park and Bushy Park; Swings, etc.: Various parks; Bathing Facilities: At the Serpentine; Hard Tennis Courts: Greenwich Park; Sun-bathing Facilities: Regent's Park; Games Ground: Hyde Park (see p. 359); and Pavilion, Regent's Park

The "Botanical Magazine."—In the recently issued Part II, Vol. CLIII (1927) of Curtis's *Botanical Magazine*, the following plants are figured and described:—Rhododendron calophytum (t. 9,173), Gaultheria Veitchiana (t. 9,174), Cyrtanthus rhododactylus (t. 9,175), Siphonosmanthus suavis (t. 9,176), Acacia rhetinodes (t. 9,177), Salvia caerulea (t. 9,178), Encyclia Mooreana (t. 9,179), Cosmos diversifolius (t. 9,180), Briggsia amabilis (t. 9,181), Potentilla nepalensis (t. 9,182) and Euonymus grandiflorus forma salicifolius. The handsome and very decorative Rhododendron calophytum was discovered by Père G. David in West Szechuan, in 1869, and was later found in the same area. This species, which produces large trusses of up to thirty fragrant flowers, white, flushed with rose, is stated to be hardy throughout Great Britain and capable of thriving in almost any good garden soil that contains not more than a modicum of lime, in a shady position with sufficient moisture about the roots. This lovely species was the subject of the Supplement Plate in the issue of *The Gardeners' Chronicle* of June 20, 1925 (Vol. LXXVII), in which issue it was described (p. 431). Gaultheria Veitchiana, beautiful both in flower and fruit, was first described by Professor W. G. Craib, in *Gard. Chron.*, Vol. LII, p. 188 (1912). It is closely allied to G. Hookeri, a Sikkim species, and although discovered by Père David so long ago as 1869, it was not introduced to cultivation until thirty-five years later, by Wilson, who sent seeds of it home to Messrs. James Veitch and Sons. This Chinese Gaultheria usually forms a more or less prostrate bush; it bears crowded racemes of white, pink-tinted flowers which are followed by striking torquoise- to china-blue fruits. It grows well in peaty soil with an abundant supply of moisture and is a useful acquisition among Ericaceous shrubs. Cyrtanthus rhododactylus is a very attractive South African Amaryllid, very suitable for greenhouse cultivation in this country as it can be had in flower in early spring provided it is grown in a loose compost of sand and loam and given free ventilation. It is free-flowering, its slender, tubular blooms, which are borne in umbels of six to eight, being rosy-scarlet. Siphonosmanthus suavis is a Himalayan plant of the Natural Order Oleaceae, and was discovered so long ago as 1838 by Griffith. This species was described by King under the name of Osmanthus, but it is, with the plant known generally as Osmanthus Delavayi, so distinct from Osmanthus fragrans, the prototype of the genus, that the generic name of Siphonosmanthus has been created for these two species. The material from which the plate was obtained was provided by the Marquis of Headfort, who states that S. suavis is quite hardy in his garden at Headfort House, Kells, Co. Meath, Ireland, where it flowers in mid-winter. Owing to its larger leaves it is more ornamental than S. (Osmanthus) Delavayi, but is, perhaps, not so free-flowering; they are both sweetly scented. Acacia rhetinodes is one of the most valuable of the florists' "Mimosas" and, next to A. dealbata, is the commonest Acacia on the French Riviera. In gardens it is often misnamed A. floribunda or A. fragrans. It may be regarded as hardy in the south-west of England, and has survived in the open at Leonardslee, in Sussex, but may generally be regarded as a free-growing greenhouse shrub or tree, producing its rather loose panicles of globular, fragrant flower-heads very freely. The home of Salvia caerulea is in eastern and south-eastern Brazil and eastern Paraguay (probably also in north-western Argentine), but it would appear to have become naturalised in Chili and about the city of Buenos Aires. It is naturally a perennial or under-shrub, but in this country is, perhaps, best treated as an annual. If sown under glass in early spring and the seedlings are planted out, they will form fine bushy plants and produce their grand, deep blue flowers freely in September and October. Autumn-sown plants flower correspondingly earlier, and as seeds are set freely, a stock may soon be obtained. This plant received an R.H.S. Award of Merit on September 21, 1926. Encyclia Mooreana, closely related to the genus Epidendrum and by some authorities included in it, is a native of Costa Rica, whence it was introduced to this country in 1888-9. At Kew, E. Mooreana is grown in a winter temperature of 50° to 55°, and the temperature is kept so low as possible during the summer. While resting during the winter, the roots of the plants are kept fairly dry, but when in growth a liberal supply of water is needed; a suitable compost is one of Osmunda fibre and Sphagnum-moss. The Mexican Cosmos bipinnatus has been given many synonyms, including Bidens dahlioides, under which it was figured in *Gard. Chron.*, in 1910 (Vol. XLVIII, p. 226, Fig. 89). It is not uncommon in gardens, and thrives in a sunny position in light, gritty soil; as it cannot be regarded as hardy, it is best to lift the tubers and store them, like Dahlias, for the winter. Briggsia amabilis is an interesting Gesneraceous plant from China which may be grown under normal greenhouse conditions in this country, but requires moist air and shade from bright sunshine. Its pendulous, wide, tubular flowers, borne either singly or in two to three-flowered cymes, have cream-coloured to greenish corollas —or dull orange—with seriate spots on the ventral side and brownish or purplish-orange spots within. The deep rose-red-flowered, hardy and free-growing herbaceous perennial Potentilla nepalensis is already popular in gardens, being especially suitable for growing in sunny positions on the rock garden. Euonymus grandiflorus forma salicifolia is a distinct and very handsome Spindle Tree from China and India. It is stated to be hardy in the south of England and Ireland, fruiting very abundantly in good years, and with highly ornamental effect.

Playing Field in Hyde Park.—Through the generosity of Sir Howard Frank, Chairman of the Finance Committee, the National Playing Fields Association has offered £5,000 to Mr. George Lansbury, the First Commissioner of Works, for the purpose of laying-out the exhibition grounds in Hyde Park as a playing field to provide facilities for football, cricket, netball, bowls, and a putting green. The offer has been accepted, and it is expected the work of laying-out the field will begin shortly.

National Trust's Scheme to Preserve Downlands.—The National Trust has under consideration a scheme which, if successfully carried out, will secure for the public practically all the downland between Seaford and Eastbourne, a distance of nearly seven miles, and also the whole of Cuckmere Valley from Birling Gap to Litlington; the acquisition of six of the cliffs known as the "Seven Sisters," is included in the scheme, and negotiations will be continued to secure the seventh from disfigurement. The land now to be secured comprises Cuckmere Haven, Hope Cave, Highover Down, Hanging Wood, Charleston Manor, Exceat Farm, Peak Dean, and six of the "Seven Sisters"; with the land already protected, a total area of about sixteen square miles will thus be secured for preservation. The ultimate cost of carrying out the whole of the scheme is not expected to exceed £25,000, and the Trust accordingly invites subscriptions from the public towards this amount.

Gardener's Widow attains her Hundredth Year.—Mrs. Ann Leighton, The Craigs, Ellon, Aberdeenshire, widow of the late Mr. Leighton, for many years gardener at Auchmacoy, near Ellon and latterly a nurseryman, celebrated her hundredth birthday on Saturday, November 2. Although a little dull of hearing, and with eyesight a little dimmed, Mrs. Leighton is yet exceedingly active, and rarely has she required medical attention. When in their prime, Mr. and Mrs. Leighton set out to attain a great ambition—the transformation of the "wilderness of the Craigs" into a profitable pleasaunce. Early and late they toiled, assisted by their young family, Mrs. Leighton putting in a day's work with the spade and on her knees among the weeds, until the Leighton Nurseries became famous in the district. They remain so to this day, but they are now known as the Johnston Nurseries, a married daughter and her husband carrying on the work so well begun by Mr. and Mrs. Leighton. The celebrations were opened with a large gathering of children, grandchildren and great-grandchildren, and many friends. After a short devotional service, Provost Cairns read the royal message sent by the King and Queen in which their Majesties hoped the centenarian would spend an enjoyable day, and that the remainder of her life would be tranquil and happy. Many other messages from all parts of the world from descendants and friends of the old lady were also read. Following this came valuable presentations and the cutting of the birthday cake with its one hundred candles. It was a memorable occasion, but Mrs. Leighton was a little bewildered over the fuss being made of an "auld wife." Her past birthdays, she declared, had just "slipp't by without muckle notice." Work hard and keep slim, is her recipe for a long life.

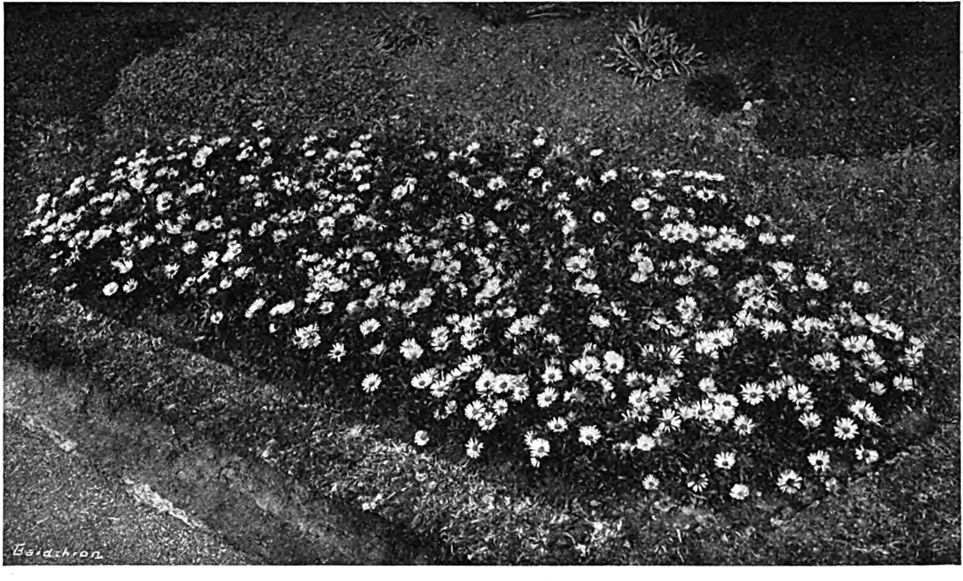

FIG. 163.—ODONTOSPERMUM MARITIMUM.
(see p. 364).

Appointments for the Ensuing Week.—Monday, November 11: Derbyshire Horticultural Association's meeting. Tuesday, November 12: Brighton, Hove and Sussex Horticultural Society's Show (three days); Birmingham Chrysanthemum Society's Exhibition (three days); Jersey Gardeners' Society's meeting. Wednesday, November 13: Gainsborough Chrysanthemum Society's Exhibition; Bristol Horticultural and Chrysanthemum Society's Exhibition (two days); Highgate Chrysanthemum Society's Exhibition (two days); Wimbledon Gardeners' Society's Exhibition; Aberystwith Chrysanthemum Society's Exhibition; Buxton and District Chrysanthemum Society's Exhibition. Thursday, November 14: Ipswich Gardeners' Association's Exhibition; Rotherham and District Horticultural and Chrysanthemum Society's Exhibition (three days); Sheffield Chrysanthemum Society's Exhibition (three days); Hitchin Chrysanthemum Society's Show. Friday, November 15: Leeds Paxton Society's Exhibition (two days); Bolton Horticultural and Chrysanthemum Society's Exhibition (two days); Whitley and Monkseaton Chrysanthemum Society's Exhibition (two days); Dunfermline Horticultural Society's Chrysanthemum Show (two days). Saturday, November 16: Burton-on-Trent Chrysanthemum Society's Exhibition.

"Gardeners' Chronicle Seventy-five Years Ago.—*Fuchsia Dominiana.*—A beautiful example of this truly gorgeous plant was exhibited at 21, Regent Street, on Tuesday last, and without any exaggeration it may be said to have been the admiration of everyone. There is now no doubt that it is one of the finest autumn and winter-flowering conservatory plants we have. The merit of raising this beautiful plant is due to Mr. Dominy, the foreman of the plant department of the Exeter Nursery; it consequently bears his name as a memento of his zeal and ability in the performance of his duties. It is a seedling between Serratifolia multiflora and spectabilis, having the fine free growth of the former and the splendid flowers of the latter.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Brazilian Miltonias.—Members of this group of autumn-flowering Miltonias that are passing out of flower, such as M. spectabilis and its richly coloured varieties, together with some of the natural hybrids, require a light and well ventilated position near the roof-glass in an intermediate temperature, in order to complete the season's growth. When this is accomplished, very little water will be needed to keep the pseudo-bulbs in a normal condition. Full exposure to all available light is necessary at this season to assist the ripening of the growths of these Miltonias so that they may pass successfully through the winter months. At this period the foliage of some varieties may turn pale yellow in colour during the ripening process, but this need not cause alarm, provided the plants are not allowed to shrivel. Later-flowering species of the Regnellii and Clowesii section should be treated in a similar manner after flowering.

Seasonable Routine Work.—With the advent of cooler weather and the consequent fluctuations in outside temperatures, especially during the autumnal gales of wind and rain, and also during quiet weather, when there is a tendency to sharp ground frosts at night, followed by bright sunshine during the middle of the day, it is difficult to follow any definite rules for the management of the various departments. At this season, great fluctuations of temperature should be avoided so much as possible, by paying strict attention to ventilating the houses, admitting air on the leeward side, especially during cold and windy weather. Careful control of the heating of the hot-water pipes should be practised. At this season, various groups of Orchids, such as Cattleyas and their allies, Cymbidiums, Epidendrums and Vandas, especially V. coerulea, require all the available light possible, with a reasonable quantity of fresh air to assist in ripening the new growths so that they may withstand the winter well. Other shade-loving Orchids, such as Phalaenopsis, Odontoglossums (notably the newly-potted plants), bulbless Zygopetalums and small seedling Orchids, may still require light shading during the brightest part of the day. In smoky districts where dirt accumulates on the glass and obscures the light from the plants, it is necessary to wash the outer surface of the roof-glass several times during the next three months, also to wipe the inside surface occasionally in addition to the general cleaning of the house. If possible the annual washing of the houses should be done early in the autumn, to allow the laps of the glass to become closed again before the cold, wintry winds arrive, when temperatures are difficult to maintain, while the extra air admitted through this operation in the early autumn tends to assist the ripening of the growths. With many Orchids, notably Cattleyas, Vandas and Dendrobiums, much less water will suffice, although complete drying off (except in the case of deciduous Orchids that have completed their growths) should not be attempted; sufficient water is necessary to keep the pseudo-bulbs and leaves in a normal and plump condition, without exciting them into premature growth.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Raspberries.—The weather conditions during the past season have not been conducive to the well-being of the Raspberry as it is essentially a moist season fruit, and it is only where the soil is of the most fertile kind, or has been deeply mulched to conserve the moisture that the young canes have grown to the average height. The canes have now lost most of their leaves and may be tied securely to the wires or other supports. In each case tie in only the best canes spacing these out, on the wires at from four to six inches apart, and remove the immature tips. All the weak canes in the rows should be cut back close to the soil level, as should also the stubs of the old fruiting canes, as this removes a means of shelter for the caterpillars of the Raspberry moth (Tinea rubiella), and the pupae of the Raspberry beetle (Byturus tomentosus. Suckers that arise some little distance from the rows should be pulled up and reserved for forming new plantations. When the tying has been completed, a good mulching of well-rotted farmyard manure should be applied to the rows, allowing it to extend outwards eighteen inches or more from the stems on either side of the row. The soil not so covered should be lightly forked over and left tidy for the winter season. Where there is a scarcity of farmyard manure, bone-meal four parts, and sulphate of potash one part, should prove an excellent substitute. The mixture should be applied at the rate of two good handfuls to the yard of row, and should be very lightly forked into the surface soil. The spade should on no account be employed between the rows as it severs the roots and increases the risk of suckering; only the very lightest form of cultivation should be employed. The autumn-fruiting kinds have fruited well in spite of the very dry conditions. For the sake of tidiness they may now be semi-pruned, the final pruning being deferred until February or March. Where it is intended to form a new plantation of Raspberries, the soil should be thoroughly trenched and well enriched with some form of organic manure, and the top layers of soil well sprinkled with bone-meal and basic slag. This preparation should be carried out at once so that the soil may settle down somewhat before the planting takes place early in February. The types of soil suited to different varieties vary, so a trial is recommended before the extensive planting of any one variety is carried out. A few of the best-flavoured sorts are Pyne's Royal, Park Lane and Red Cross; while for bottling or preserving the varieties Lloyd George, Laxton's Prolific and The Devon are excellent in every way. The Hailshamberry, Lloyd George and November Abundance are a few of the best autumn-fruiting varieties.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Shrubs for Forcing.—Flowering shrubs are very useful subjects for producing a wealth of bloom during the early spring months, and they can be used either for cut flower purposes or for bold grouping in the conservatory or dwelling-house; for the latter purpose there is nothing to surpass them for the small outlay they incur. To mention only a few that may be successfully flowered under glass, perhaps the following are the most suitable:—Lilac, Prunus, Pyrus, Viburnums (including the sweetly-scented V. Carlesii), Spiraeas, Wistarias, Japanese Cherries, Kerrias and the many varieties of Cytisus. Intending growers of these delightful subjects should procure stocks so soon as possible, placing them in receptacles of suitable sizes directly they are received. Plants that have been specially grown for this purpose give the best results. After potting, they should be stood out-of-doors, plunging the pots to their rims in ashes; during severe frosts extra protection is necessary to prevent the receptacles being broken. When the time arrives to start the shrubs into growth, it is wise to commence with a low temperature and gradually increase the amount of heat each week until an intermediate temperature is reached.

Carnations.—Plants which were housed during the month of September are now producing flowers in abundance and have made considerable growth since that time; the work of disbudding needs constant attention, and in some cases the removal of surplus growths may be necessary. Close staging of the plants should be avoided so far as possible to prevent the growths becoming weakly. The atmosphere of the house should be kept buoyant by careful ventilation night and day, and only during severe weather with cold, east winds, should the top ventilators be closed; maintain a steady circulation of warm air throughout the house by the aid of the hot-water pipes at night and during dull, sunless weather. Continue to feed the plants lightly, but heavy feeding should be guarded against, or weak growth and burst calyces may result. Rust and red spider are enemies to Carnations, and where they are not yet very much in evidence, three ounces of salt thoroughly mixed in two gallons of water will act as a deterrent to them if sprayed on the plants with force occasionally; in very severe cases of attack Volck—used according to directions—should be employed.

Propagating Carnations.—The propagation of Carnations should now be carried out. The young shoots for this purpose should be selected carefully, choosing those from healthy plants only. Some growers favour rooting the cuttings in clear sand, but here we root them in equal parts of loam and sand, in a temperature of 55°.

Watering.—At this season of the year and during the coming winter, much care is needed in giving water to plants. With the lower temperatures maintained in all plant houses during the winter, there should be a corresponding reduction of atmospheric moisture, and during cold, damp weather the floors should be kept comparatively dry. Watering, generally, should be done early in the day to allow the superfluous moisture to disperse somewhat before night. Endeavour always to maintain a free circulation of air, except when severe frosts or foggy weather prevail.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—Owing to the present mild and fine weather, late Strawberry plants are still making leaves, a condition which necessitates keeping the earliest plants as inactive as possible and fully exposed in an open part of the garden. If very early Strawberries are wanted, now is the time to select plants most suitable for this purpose. Those with hard, red, single crowns, and which have filled their pots with roots, are most likely to respond to gentle forcing. If the plants are well plunged, they should not need much water, but any state approaching dryness should be avoided. If red spider or mildew has been troublesome, each plant should be immersed in sulphur water before being taken inside. The general stock of Strawberry plants should be moved occasionally to prevent the roots leaving the pots, and more room may be given at the same time to let light and air among them. Nothing will be gained by feeding the plants after this date; any plants which were put out in August for supplying forcing runners for next year should be treated as carefully as those grown in pots.

Early Figs.—Early Figs, whether grown in pots or borders, have had a fine season for ripening their wood and roots, and should be in excellent condition when the time arrives for starting them in December, that is, if ripe fruits are wanted early in May. Pot trees, as a rule, are most in favour, and for very early work are preferable to permanently planted trees, not that the crops they produce are heavier, earlier or better, but they can be moved or changed in the event of failure. Trees for very early forcing should be thoroughly ripe and well furnished with embryo Figs, and they should be fairly root-bound, a condition which can be secured by reducing the roots and repotting, or giving a small shift early in the autumn. Unless these essential factors are present, no benefit will be gained from an early start. If trees are still out-of-doors, where they have received very little water since the end of September, they should be taken in and the crocks examined, and the wood, young and old, carefully washed with soapy water, care being taken that the young Figs are not scratched. If the presence of worms is suspected, a soaking of lime-water should remove them. Bottom-heat being an important factor, this should be provided by the introduction of fermenting material consisting of Oak or Beech leaves and a little stable manure to a depth of about two feet. Place the trees in position and gradually water the trees to get the balls of soil and roots into good condition by the time the fermenting material is introduced and the trees started.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Dahlias.—These, in many places, are now damaged by frost, and the growth may be cut down, leaving a good length of stem so that the labels of the various sorts may be securely attached to them preparatory to lifting and storing the tubers for the winter. When lifted, the tubers should be exposed in a frost-proof shed and allowed to dry a little. With such treatment they should keep much better during winter than if put away so soon as they are lifted. Any shed or cellar will do as a store-room, provided it is frost-proof. There are so many varieties of Dahlias in the various sections of equal merit, that to make a selection one must be guided by individual taste and the purpose they are required for. While the large collections so well grown and arranged in the various public parks are of extreme interest, for the private garden a few of the very best varieties in large beds or borders are more useful. Varieties for this purpose should include Reginald Godfrey, a really good scarlet of erect growth and free-flowering, the flowers being borne on stiff, wiry stems well above the foliage. A later introduction, Bishop of Llandaff, is a Miniature-flowered Paeony Dahlia of a rich, bright crimson, and should prove of great merit for bedding. Mrs. A. S. Galt is a delightful, bright scarlet Dahlia with dark purple foliage, while a large-flowered Decorative variety of this colour is Mevrouw Ludwig. Seafield, a charming pale rose with a deep orange base, is one of the best of its colour, having stiff, wiry stems, while the colour shows well under artificial light. A good companion to this will be found in Mrs. H. C. Scrimgeour, with flowers of a deeper orange. Our Annie is still one of the best for bedding purposes. Pink Pearl and Pink Perfection are also to be recommended. Among the large Decorative sorts of this shade, Jersey Beauty is probably the best. Others belonging to the same section, of proved merit for garden decoration, are H. B. May, pale orange-salmon, with white tips; White Friar and White King; and W. D. Cartwright, free-flowering, orange-yellow, with the flowers held well above the foliage. Among the small-flowered Decorative sorts, May has been very free-flowering; Rose Elegance, Cheal's Pink and Freda can also be recommended. Some of the older varieties are not to be despised for bedding purposes; such well-tried favourites as Dobbie's Bedder, Barlow's Bedder, Crimson Flag and Prestige are all useful where masses of colour are wanted. Few new varieties of outstanding merit have been added to the bedding section during recent years, such well-known kinds as Coltness Gem, H. J. Jones, Kingcup, Lady Aileen, Julius, Paisley Gem, L'Innocence, Kathleen, and Pink Coltness Gem, being still the best. The Cactus Dahlias, generally, from a garden point of view, still leave a lot to be desired, but they are improving every year; those of recent introduction that have reached the standard of a plant useful for garden decoration include Pink Favourite, La France, Alice Amos, Mrs. Stuart Sandeman, Redpole, Snow Bunting, Stedfast and Edeghem.

Begonias.—Tuberous-rooted Begonias that have been lifted from beds in the open should be placed in a position where they can be dried off, afterwards picking them over and storing in a dry, frost-proof shed.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Vegetables in Store.—On wet days, when no work can be done out-of-doors, Potatos in store should be gone over carefully and any bad ones cleared away. Onions, and any other stored vegetables, should also be inspected.

Seed-sowing.—A few rows of Broad Beans, also early Peas of the round-seeded type, may be sown in a south border.

Broccoli.—Plants of Broccoli should be heeled over before severe weather sets in. This is done by removing the soil on the north side, inserting the spade its full depth on the opposite side, and tilting the plants over to the north making them firm at the base by treading the soil about them as the work proceeds.

Runner Beans.—As this crop is now finished, any pods that have been left for seed should be picked and laid on a dry shelf to thoroughly ripen the seeds; the sticks should be pulled, cleared of the Bean stalks, and tied up in bundles and placed under cover for use next year. The position of the rows should be marked, as next year Parsnips, Carrots, etc., may be sown where the Beans were grown.

FIG. 164.—PLUMIERIA BICOLOR.
(see p. 362).

Salsify and Scorzonera.—The roots of these may now be lifted, using a spade for this purpose, as the roots are very easily broken. Trim off the foliage and arrange the roots neatly in a heap in a place were frost cannot reach them, and cover them with plenty of sand.

Celeriac.—Those that are sufficiently large should be lifted and after being cleared of their leaves, removed to a cool place and placed in sand.

Jerusalem Artichokes.—The tubers of Jerusalem Artichokes may now be lifted and stored in sand. The largest tubers should be used for culinary purposes first, as the smaller tubers are best for planting next year.

Cabbages.—Early plants may have some soil drawn up around them to steady them and protect the stems in frosty weather. If plenty of soot is available, a dusting around the plants and between the rows before drawing the soil around the plants should benefit them, and also ward off slugs.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

St. Brigid Anemones.—The plants of these sown in March or early April are now in full flower and should be protected from rain and frost to prolong the season for some time. A framework of wood over the plot, on which lights of frames can be placed, is ideal for the purpose, and mats may be hung around the sides when frost threatens.

Roses.—If any planting of Roses has to be done no favourable opportunity should be lost. The ground should be dug deeply and manured heavily, and should be of a heavy, rather than light, nature, but clay should be avoided; if planting has to be done on clay soil, quantities of opening materials should be added when preparing the ground. Owing to our uncertain climate, it is best to plant the bushes as the preparation of the soil proceeds, as if the soil is left to settle, rain may make planting impossible for weeks to come. British-grown Roses should be used every time, being infinitely superior to any imported stuff. The Briar, a deep-rooting stock, is best for strong to heavy soils, and the Manetti, a more surface-rooting stock, for light or sandy soils. In selecting the plants, it should be borne in mind that the root-system is of more importance than the top-growth; the former should be abundant and fibrous, and the latter only moderate in strength. Gross wood shows over feeding in the nursery, and such plants do not respond well to removal. When planting, make the ground firm before and after placing the bushes in position, and have the roots spread out to their full extent, and the point of union with the stock buried a few inches below the soil. Should severe frost be experienced, extra soil should be drawn up around the collars of the plants, this being the best form of protection, and not so unsightly as manure or straw.

Sweet Peas.—Autumn-sown Sweet Peas have made rapid progress owing to the mild weather, and should be stopped when they have made a few joints with at least one pair of good leaves; they should be exposed to so much air as possible while mild conditions prevail.

Cuttings.—Zonal and Regal Pelargoniums rooted in August and early September should be kept dwarf by pinching out the growing points, and they should, where possible, be potted singly into two-inch pots, using a fairly light soil for this purpose. Water should be given with great care during the winter months, a spraying on good days being generally sufficient, as artificial heat should only be given to exclude frost.

Mignonette.—As the roots begin to encircle the ball of soil shift these into pots two inches larger, using a compost of three parts good loam, one dried cow manure, and a little sand and lime rubble. Water the plants previous to shifting them, so that no water need be applied for a few days after repotting. Avoid the use of artificial heat, or weak, sickly growth may result.

Primulas.—Seeds of the many varieties of Primulas and Polyanthuses should now be sown in boxes of light, sandy soil, and placed in cold frames. Glass may be placed over them if there is danger from mice, but otherwise it is not necessary or advisable at this season. For all hardy Primulas a good freezing seems to be of service in inducing rapid germination, therefore it is perhaps best to sow these in pots and place them against a wall with a north exposure, covering them with glass to protect them from heavy rain.

INDOOR PLANTS.

PLUMIERIA BICOLOR.

THE accompanying photograph (Fig. 164) is of Plumieria bicolor. The plant flowered quite recently at Cambridge Botanic Garden, and remained in bloom for over six weeks. The flowers are nearly two inches in diameter and open successively. They are quite waxy in texture, deep yellow in the centre, shading out to pure white on the extreme edges. *F. H. Wright, University Botanic Garden, Cambridge.*

PHASEOLUS CARACALLA.

BELONGING to the same genus as the edible Runner and French Beans, Phaseolus Caracalla is of interest to the gardener by reason of its curiously-shaped flowers rather than for any utilitarian purpose. It is a native of India, but has been naturalised in other warm countries, notably in parts of California. The twining stems may attain a height of twenty feet or more. The leaflets which compose the trifoliate leaves are broadly rhombic-ovate, acuminate or pointed.

The flowers are borne in axillary racemes that exceed the leaves. They are large and fleshy, with the keel twisted in a curious snail-like manner, a character which has earned for this plant the names Snail Flower and Corkscrew Flower. Each flower is large and fleshy and of an undecided mixture of pale purple and yellow —not particularly striking in appearance but possessing a strong Stephanotis-like odour, which is an added attraction. It succeeds under warm-house conditions, and appreciates a light position close beneath the glass, and it may be treated as a perennial or as an annual.

Phaseolus Caracalla, which received a rather belated Award of Merit from the Royal Horticultural Society on October 8 (see p. 293), was first introduced to cultivation in 1690. A closely related species is P. Bertonii, from Paraguay.

LANTANA SELLOWIANA.

LANTANA Sellowiana (or Selloviana, as it is sometimes written) is named in honour of Dr. Sellow, of Potsdam, who travelled in Brazil for a number of years. It was first introduced to cultivation in 1882, and may be recommended as a fine subject for pot or basket culture, while with suitable training it develops into a good standard. It is of slender, twiggy habit, with procumbent or trailing branches. The margins of the small, ovate leaves are closely toothed.

This Lantana is very profuse and continuous in the production of its blooms, the inflorescences greatly resembling those of a Verbena. They are of an attractive rosy-lilac colour—a tone which appears particularly pleasing under artificial illumination. The individual flowers are small, but they are aggregated in long-stalked heads, each about one-and-a-half inch to two inches in diameter. The involucral bracts are less than half the length of the corolla tube. The flowers exhale a delicate perfume, but the foliage and stems emit an odour which is disagreeable to many people. This is not noticeable, however, unless the leaves are brushed against or bruised.

As with all members of the genus, the species under notice revels in hot, sunny weather, and it is only seen at its best where such conditions prevail. It is readily increased by means of cuttings taken from stock plants in the early spring. These root readily in pure sand with a bottom heat of 70° to 75°. After rooting, they should be grown on in an intermediate temperature and potted on as growth necessitates. After all danger of frost has passed, they may be planted in the open ground. If hanging baskets are desired, use several young plants, and grow them on in a sunny position in the greenhouse.

Dealers in the United States sometimes list L. Sellowiana as the Weeping or Trailing Lantana, and it is also known in the trade as L. delicatissima (which is a distinct species). A native of South America, L. Sellowiana occurs as a garden escape in the state of Florida. *T. H. E., New York, U.S.A.*

ORCHID NOTES AND GLEANINGS.

PLATYCLINIS COBBIANA.

ONE of the daintiest Orchids to bear their blooms at this season of the year in the warm Orchid-house is Platyclinis Cobbiana (syn. Dendrochilum Cobbianum).

The plant was introduced during 1881, from the Philippine Islands. The blooms are very curious and pretty, for about fifteen are borne in a pendulous raceme at the apex of a fine stalk a foot in length, and they are placed zig-zag fashion in two rows down the raceme. Individually, they are about half-an-inch in diameter, straw-yellow in colour, with a deeper orange-yellow lip. They possess a very faint, but none the less delightful, odour, somewhat like the scent of resin, and the whole inflorescence is very finely made, and sways about at the slightest movement of the air about it, like some giant catkin.

The leaves are six inches or so in length, about one-and-a-half inch broad, and contract gradually towards the base in a petiole which ends in the pseudo-bulb. These pseudo-bulbs are from one inch to two inches high

A compost composed of the fibre from peat, and Sphagnum-moss, with a little crushed charcoal to correct acidity, is all the plant requires. This Orchid should be grown in very well-drained pans hung near the roof of the house, in a light, but not sunny, position.

An abundance of water is essential during the growing period, while even during the resting season the plants should never be allowed to become dry. *F. H. Wright, University Botanic Garden, Cambridge.*

BULB GARDEN.

FRITILLARIA CITRINA.

FRITILLARIA citrina is one of the smaller-flowered species of the genus which does not attract the average plant lover but which, like some others, appeals to the rock gardener, and constitutes a pleasing feature in his garden. It is a native of Cilicia, and grows about six inches high. It has narrow leaves and bears its flowers during April and May in pairs. These may be described as "greenish-yellow," with glaucous bloom on the segments. It is by no means a showy plant, but is quite attractive in the rock garden, in groups of twelve or more.

F. citrina has proved perfectly hardy with the writer for a long series of years. It increases by offsets or seeds, but the latter, even when sown so soon as ripe, will not produce flowering plants for four or more years. Planting should be performed so soon as the bulbs can be procured, planting them at a depth of an inch, in light, rather sandy soil. I find F. citrina thrives well either in full sun or in the shade of a small, deciduous shrub. *Dumfriesshire.*

FLOWER GARDEN.

HOLLYHOCK PALLING BELLE.

THIS old variety is still one of the best pink Hollyhocks. It was brought to light by the late Mr. W. Watson, who found it some twenty years ago in a garden on the east coast. The flowers are large and fully double, and the colour is a beautiful pure pink. The usual array of flat petals at the back is, in contrast to the double centre, of a delicate, soft, shell-pink.

Attaining a height of seven or eight feet, this is a very useful variety for the herbaceous border, or for grouping among dwarf shrubs. It is most effective when massed in a bed on the lawn, with a background of trees and shrubs. In such a position the beautifully clear tone of the flowers can be fully appreciated, each bloom as soft, silky and crinkled as a double Poppy. The great objection to beds of Hollyhocks lies in the tendency for them to become bare and ragged at the base, but this defect could be remedied by "facing" the bed with a narrow band of some dwarf herbaceous or annual plant. One would naturally select a colour that would harmonise with the Hollyhock, and tall orange Antirrhinums could probably be used to good effect. A pale variety of Pentstemon would serve the purpose, but the more vividly coloured varieties should be avoided.

Although double-flowered, Hollyhock Palling Belle sets seeds, and these produce plants which are true to the parent. Hollyhocks appreciate a rich soil, and this may be secured by the addition of leaf-mould and manure to ground of poor quality. A top-dressing of old manure just as the flower spikes are being produced, is advantageous, for its value as a mulch, in addition to the manurial benefit which results.

Propagation may be effected by seeds sown outside from April to July, or by division, or by cuttings from the bases of the old plants. These may be struck in pots, plunged in a cold frame. *C.*

ROSE GARDEN.

SOME GOOD ROSES.

Now that the Rose planting season has arrived I should like to pay my tribute to the beauty of certain varieties which have done well in my garden this year.

I have a large collection of varieties, among which Gwyneth Jones is the most brilliant carmine-orange sort; occasionally the variety bears double flowers, but the majority are semi-double. This, however, does not detract from their charm. The variety is almost immune from mildew, and is very free-flowering. Lady Forteviot is somewhat unusual because when the flowers open they are golden-yellow, becoming apricot with age. In my opinion the fine form of the blooms of this variety stamps it as an exhibition flower; incidentally, its fragrance is exquisite.

One of the most brilliant orange-scarlet Roses is found in the variety Margaret McGredy, although my bushes of this are planted in extremely light soil, the colour of the blooms is not in the least affected by the sun; it is free-flowering and fairly resistant to mildew. I believe the variety Fragrance, which bears deep crimson flowers, must be one of the most sweetly-scented of modern Roses. It is worth growing on that account alone, but reference may also be made to the charm of its deep crimson blooms, and the freedom with which they are produced.

Although somewhat old as Roses go, Florence is still worthy of an honoured place, for its silvery-pink flowers, pointed in the bud, are the last word in refinement. *Geo. H. Copley, Yorks.*

HARDY FLOWER BORDER.

ACONITUM ORIENTALE.

ALTHOUGH the blue-flowered Aconitums or Monkshoods have long been established favourites in English gardens, the yellow-flowered species seem never to have been recognised to any extent, although several of them are noteworthy, and by no means to be despised where the planting of large herbaceous borders has to be carried out.

One of the best of these yellow-flowered Monkshoods is A. orientale (syn. A. ochroleucum), a native of the Caucasus, and a free-growing, herbaceous perennial which, during summer, produces from a basal mass of dark green foliage, a compact column of tall sprays of blossom up to a height of about three-and-a-half feet. The flowers are more tubular and narrow than those of the blue-flowered species, and the typical hood is not so pronounced, while the colour is a good shade of creamy-yellow. The flowers are produced plentifully and over a fairly prolonged season, and if the growths are loosely supported, as is necessary with most medium to tall herbaceous plants, a very charming subject results.

Among other yellow-flowered Aconitums, A. Lycoctonum and A. L. var. pyrenaicum may be noted specially. The former is a distinct species which attains a height of about four feet, with its dense spikes of pale sulphur-yellow flowers, while the large blooms of A. L. var. pyrenaicum are a good yellow.

If space cannot be found for these Aconitums in the herbaceous border they may, with the blue-flowered sorts, be planted in open positions in the wild garden, preferably away from the drip of trees—and there left to fend for themselves, with not unsatisfactory results. *M. W.*

TREES AND SHRUBS.

POTENTILLA FRUTICOSA VAR. BEESIANA.

The shrub sometimes listed under the above name is apparently identical with P. f. var. argentea nana. Whatever its proper name may be, it is certainly one of the most delightful of the numerous and confusing varieties of the shrubby Cinquefoil.

Growing in rather poor soil it has not exceeded a couple of feet with me, and instead of sprawling or becoming thin and gawky it has maintained a compact, well-rounded, bushy form. The leaves, which are broadly and bluntly lobed rather than deeply cut, as are those of so many, are silvered with a silky down and the big, well-rounded blossoms are a good, full-toned yellow. These blossoms, moreover, are borne in extraordinary profusion from spring to late autumn. Indeed, there is not another shrubby Potentilla in a fairly representative collection which flowers with such unwavering persistence the season through as this little bush. Cuttings strike quite readily in a cold frame, and these will often begin to bloom when only a few inches in height.

LEPTODERMIS PILOSA.

Under the above name, a shrub was sent to me some years ago, which has ever since been a very pleasing object in a quiet way throughout the summer and autumn. Whether it has any right to its label, I do not know, no books or catalogue by me (including the Kew *Hand List*) being of any assistance in identifying it. However, this is a deciduous species, and it has made several slender upright growths to a height of some five or six feet. The bark of these is a reddish-grey and they are sparsely set with short stiff twigs upon which are disposed with no less economy the opposite, ovate, grey-green, slightly hairy leaves, each with a pair of leaflets at its base. From midsummer onwards to November this shrub yields a succession of bright lavender-coloured tubular flowers half-an-inch long. These are borne in clusters at the leaf-axils of the younger wood and they have a delicious Daphne-like fragrance. The shrub appears to be quite hardy in the very dry, stony soil in which it is growing and if not particularly striking its autumn flowers and sweet scent do more than earn it a place. *North Wales.*

STRANVAESIA DAVIDIANA VAR. UNDULATA.

On November 11, 1928, an Award of Merit was granted to Stranvaesia Davidiana by the Royal Horticultural Society. This is a very beautiful shrub, and no doubt it fully deserves this distinction. The species figured prominently in the recent Autumn Shrub Show of the Society, when the brilliant red berries attracted a good deal of attention. There is, however, a variety of this species, which was introduced from China about the same time as S. Davidiana, and which is apt to be overshadowed by the latter when one is selecting shrubs which are particularly desirable. This is S. D. var. undulata, a hardy evergreen shrub which flowers profusely and produces an abundance of most attractive red berries.

In contrast to the type, the variety undulata is much less erect in habit, forming a spreading shrub, which may reach twenty feet in height, but is often considerably less than this. It has evergreen, pointed, glossy, broadly lanceolate leaves from one-and-a-quarter inch to three-and-a-half inches long and about a third as wide, often with undulated margins, and borne alternately, each on a short stalk. In June, corymbs of white flowers, each bloom half-an-inch across, are borne terminally on the branches. Typical of Rosaceae, there are five petals and numerous, rather prominent stamens. The flowers are followed by bright red berries, each about one-third-of-an-inch in diameter.

The foliage of S. undulata frequently turns crimson before leaf-fall. This autumn colouring is common also with S. Davidiana, which is quite possibly a better plant. However, the variety undulata has its uses, although it requires rather too much room for those with small gardens.

The Stranvaesias prefer a fairly light soil, but S. D. var. undulata may often be seen growing quite well in a heavy loam. Propagation may be effected by cuttings of firm, half-ripened growths, if possible, taken with a heel, and inserted over slight bottom-heat. S. D. var. undulata is, by some authorities, accorded specific rank. *L. B. C.*

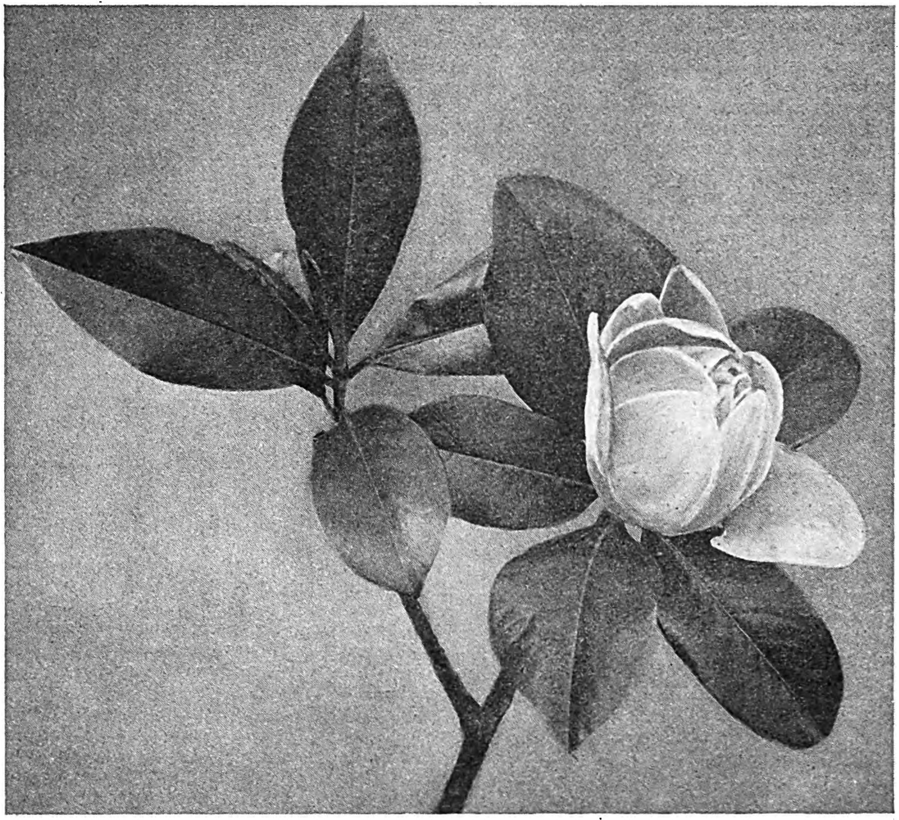

FIG. 165.—MAGNOLIA PARVIFLORA VAR. PRECOCE DES NANTES.
(see p. 365).

CEANOTHUS AZUREUS VAR. HENRI DESFOSSE.

There may be superior hybrids of its colour, but I have not seen anything in this class of Ceanothus to equal this variety in the richness of its blue and the extent of its flowering period. Grown in the open, this shrub breaks into flower quite early in summer, it is at its best about August, and continues without a break until well into autumn. The very large inflorescences branch freely, making big trusses of blossom, and the latter, being an intensely rich indigo-blue, the effect of a well-grown bush is surprisingly lovely. I do not know how this variety compares with Indigo in the matter of colour, for I have not grown the latter, but I see that Mr. Notcutt, who sent me my plant, considers Henri Desfosse the darker shade.

The Ceanothuses of this section are doubtless best when grouped and a pure white makes a fine foil for these deep blues, but I find a single bush of such a one as the subject of this note a most useful and attractive object in a mixed border.

CORONILLA GLAUCA.

If this garden is just far enough from the sea to render the growing of this delightful shrub a hazardous proceeding, the fact that it can nearly be successfully wintered does not tend to damp one's aspirations. Were the plant a less worthy species matters might be different, but Coronilla glauca is a thing of such irresistible charm that its replacement every time it succumbs is carried out with a stoical disregard of fate. However, it is only really severe frosts, such as those of the past two winters, which C. glauca cannot endure here. In a dry, gritty soil I have seen it survive frosts which have destroyed several of the Cistuses. Nor does it surrender easily. Very few shrubs that I am acquainted with can withstand bark-splitting to such an extent as this one and yet make brave efforts to carry-on.

C. glauca, a native of Spain, is a lover of rocky, limestone places. It makes a nicely rounded bush some three to four feet tall, the evergreen foliage being of a soft, glaucous green. Although it is seldom out of bloom in genial seaside places its happiest season is late summer to winter, when a well-grown specimen will be ablaze with the rich yellow of its innumerable flower clusters. Not only are these singularly attractive in combination with the bluish sheen of the leafage, but they are deliciously fragrant. This scent is so reminiscent of the "Sunny South," awakening so many memories of blue skies and bluer seas, that to encounter its subtle appeal in November is apt to develop yearnings difficult to suppress.

C. glauca strikes so readily from cuttings that one need never be without a reserve stock, and plants so raised grow so fast and flower at so early an age that they often give bloom the following season. It is also quite amenable to life in a pot, making a useful cold-house shrub which may be put outside for summer and autumn. *A. T. Johnson, Conway.*

ALPINE GARDEN.

ODONTOSPERMUM MARITIMUM.

I was interested in Mr. Arnott's account of Odontospermum maritimum (p. 303), and therefore enclose a photograph of a small bed of it (Fig. 163, p. 359) taken on October 24. The plants have given a mass of yellow flowers all the summer, and look like continuing to bloom until severe frosts occur.

In an ordinary season, this Odontospermum appears to do best in a hot, dry position on the rock garden, but, as all situations have been hot and dry this year, it has flourished wherever planted. We raise hundreds of plants annually, and find them very useful for large groups on rock work, small beds and, in some cases, use it as a change to the ordinary edging plants for large beds. I agree that Odontospermum maritimum is not too hardy, and the winter has to be a comparatively mild one to allow it to survive. Not one plant came safely through the past winter in any of our gardens here. I have, however, known several winters when plants have come through unharmed at Scarborough, especially when growing in a dry place on the rock garden, or on a wall, and, by-the-way, it makes a good wall plant. We root the cuttings in a cold frame along with Calceolarias, Pentstemons, etc., and usually plant out into summer positions straight from the cutting beds.

Since writing the above, I have heard from a gentleman who was here recently—unknown to me—asking for cuttings of this Odontospermum and telling me how much he had admired it. He wrote: "It is so fresh and clean-looking and surely hardly deserves Farrer's uncomplimentary remarks."

Given a summer such as the one just over there are certainly very few plants to equal Odontospermum maritimum for freedom and continuity of flowering. *J. Clark, Parks Superintendent, Scarborough.*

LINARIA ALPINA.

Linaria alpina needs no introduction to the gardening public, although it certainly deserves a word of praise occasionally. This tiny Snapdragon (one hesitates over that awful name —Toadflax) is an old favourite which will always be grown, especially by those who make their annual pilgrimage to the mountains, and see it growing under natural conditions.

Wherever one goes in the Alps, L. alpina keeps cropping up, preferring the granite formations, but not objecting to calcareous localities, and seeking out the barren, stony slopes, at fair elevations. For instance, there is one spot (and there must be many similar places) close to a primitive slate quarry, where its thin, grey, sparsely-leaved stems meander in and out among the rubble of a shaly and almost precipitous slope, here and there peeping out at the world with those delightful little flowers which Mr. Elliott so aptly describes as "miniature violet Snapdragons with eggy lips."

It would, indeed, be a stroke of luck if one could have such a rough slide of rubble in the garden, with water flowing beneath, and there grow L. alpina as it loves to grow, not with the flat, green luxuriousness of the pot-grown plant, but with thready, grey stems that are covered by falling scree and then come up again unexpectedly with a flower or two here and there. However, all we can do for the alpine Linaria in our gardens is to grow it in the moraine, or else in a gritty mixture in some carefully selected pocket where moisture can collect and drain away almost immediately through the sharpest of drainage. Flowering all through the summer months from June to the end of September, or even later, given warm, sunny days, L. alpina will often reward the gardener by reproducing itself from self-sown seeds. Otherwise, it is to be raised (with varying success) from seeds, or else bought as plants, which usually look remarkably healthy in pots.

There is a white form of which the writer has heard but not seen, although he has had the acquaintance of varieties which were reputed to be white, and were of a dull bluish or pinky-whiteness of no particular merit. However, no white form, even if it be a true albino, can ever equal the type, and is only to be regarded as a rarity of interest—certainly not as an improvement.

L. alpina cannot be stated to have a long life under garden conditions, even although it receives annual top-dressings of gritty material, and this, perhaps, will help to keep the name before us in the trade lists. Every year L. alpina appears in catalogues, and this will be so as long as rock gardens and alpine enthusiasts exist. *L. B. C.*

SAPONARIA CAESPITOSA.

Although, from a decorative point of view, the deservedly popular Saponaria ocymoides ranks foremost in its genus as a rock garden subject, being invaluable for clothing rocks and for draping miniature cliffs, there are other members of the genus which deserve recognition of their charms, notably S. caespitosa, which will provide a bright splash of colour during mid- and late summer and which, like S. ocymoides, asks no special favours to induce it to flourish.

It is hardy and a good perennial and requires no more than an open, sunny spot and well-drained, sandy soil, with an occasional top-dressing of open compost worked among its growths.

S. caespitosa is of neat habit, being neither rampant nor straggling in growth. It forms a close carpet of smooth, narrow, dark green foliage, above which are borne on strong stems six inches or so high, dense heads of rosy-pink blooms, further colour being provided by the red-tinted calyces and stems. S. caespitosa does not rank among the unobtainable, for it is listed by several nurserymen, and is easily increased. *M. W.*

NOTES FROM WISLEY.

There are certain trees and shrubs which, no matter what the climatic conditions may have been throughout the year, take on their bright autumnal garb with unfailing regularity, and as Wisley is well-furnished with such, the gardens now present a very attractive and interesting appearance, even although many subjects have not coloured so well as is expected of them.

Amelanchier canadensis never fails to colour well in the autumn, and the fine standard of this ornamental tree (valued also for its very charming, although fleeting blossom) situated at the foot of the rock garden, has been a grand study in burnished gold, while close to it the large mound of Forsythia has become deeply shaded with purple.

The rock garden possesses many interesting features, including several specimen bushes of various Cydonias, all heavily laden with golden-yellow fruits, and several dwarf Cotoneasters with large crops of berries in shades of red. Polygonum vaccinifolium ignores the lateness of the season, and is at present draping the rocks with numerous spikes of rosy-pink, which show to advantage against the close mat of dark, glossy green foliage, and the bed of Parochetus communis—the dark blue-flowered form—in the gulley which feeds the bog garden, is still lit up by the dainty Pea-like flowers. Gentiana Farreri has finished for the season, but the luxuriant beds of G. sino-ornata are still sheets of rich blue, while an attractive shrub on the rock garden is Abelia grandiflora, whose remaining pale pink blossoms blend well with the red-tinted calyces of those that have gone before to produce a most charming effect. Stranvaesia Davidiana var. undulata, of which there is a large specimen on the border of the bog garden, is a mass of rich red fruits.

Vivid autumn colouring is found along the path leading from the Rose walk—where, incidentally, the dwarf Polyantha Rose Crimson Orleans continues to flower gaily—to the rock garden, for here the collection of Japanese Maples presents a rich study in shades of yellow, bronze, orange and flaming scarlet, while beneath them Cyclamen neapolitanum is naturalised, so that the mossy mound is dappled with rosy-pink. From this path a good view is obtained of Liquidambar styraciflua, which rises above the Rhododendrons in the woodland and is a pyramid of rich colour ranging from orange to deep scarlet. This Sweet Gum colours well in the autumn every year but, curiously, another specimen some little distance away but in the heart of the woodland, fails to do so.

On the margins of the ponds at the foot of the alpine meadow the large clumps of Osmunda regalis have changed from light green to light brown, in keeping with the general autumnal effect, while the large crimson fruits and purplish undersides of the foliage of the American Cranberry, Oxycoccus macrocarpus, in the Sphagnum-bed by the Wistaria bridge, are also very striking.

In the wild garden, Cyclamen neapolitanum is again in evidence, and the foliage of isolated clumps of Azaleas presents delightful shades of yellow and orange, although the large bank of Azaleas is practically devoid of autumn colouring. The invaluable Pernettya mucronata which is naturalised in part of the wild garden, is fruiting freely, its fruits ranging in colour from pure white and pale pink to deep crimson, and also varying considerably in size, while Gaultheria procumbens, an invaluable ground-cover, has its close carpets of dark green, purple-tinted foliage spotted with scarlet berries.

Near the Umbrella Pine, Sciadopitys verticillata, several Vacciniums are richly coloured, notably V. corymbosum, with vivid orange-scarlet autumn foliage, and V. virgatum, whose rich green foliage is lightened by the red tints of the younger growths. A plant worthy of note in this quarter, as being permanently attractive, is Pieris japonica var. variegata, the evergreen leaves of which are edged with cream and show well against the dark background of tall Rhododendrons; I do not remember ever having seen this specimen in flower, but it is a handsome foliage plant. Near to it, Hydrangea paniculata carries its numerous cream-coloured inflorescences, lightly tinged with pink, but the first frost of moderate severity will destroy them.

In that section of the wild garden known as the American garden, the Enkianthuses and Vacciniums are the chief sources of attraction at the present time. The foliage of Enkianthus japonicus is now vivid orange-scarlet, that of E. campanulatum being of a lighter, more yellow tone. Here, the several shapely bushes of Vaccinium virgatum are fruiting heavily, the fruits being blackish-crimson when ripe, and conspicuous among the tinted foliage. Vaccinium pennsylvanicum is also very striking, forming low, spreading mounds of verdant green, lightly shaded with red. The slender-pointed leaves of Leucothoë Catesbaei, carried on graceful, wand-like growths, are now heavily suffused with purple.

Seven Acres presents an animated scene, for here are to be found many bright-foliaged and richly-berried shrubs, chief among which are the Barberries. The Wisley hybrid Barberries which are planted *en masse* on a mound near the pond, and also on both sides of the broad path leading to the river walk, present a fascinating spectacle of vivid colouring in subtle shades of orange and red, while a great variety in form of fruit and the mode of bearing them is also noticeable. In the huge shrub border are many evergreen and deciduous, red-fruited species of Berberis, especially noteworthy among the former being B. replicata, which, besides being a first-class early-flowering shrub of moderate height, and compact, bushy growth, in autumn changes the colour of its oldest leaves to brilliant orange-scarlet, and also loads its branches with dark purple fruits. B. Jamesiana is barren of fruits this season, but its foliage is richly coloured, while B. dictyophylla also presents itself as a grand subject for autumn effect; it has orange-scarlet-tinted foliage and crimson fruits, and the young growths and leaves are covered with waxy "bloom." B. Prattii and B. ruscifolia are two very striking red-fruited species, the slender, oval fruits of the latter species being borne in pendent clusters, while the crimson growths of B. yunnanensis make this species an outstanding subject in the shrub borders at Wisley. The numerous Cotoneasters, except the invaluable C. rotundifolia, are not fruiting so well this year, but two yellow-fruited Pyracanthas are worthy of note, one being an unnamed seedling with every branch closely packed with small, light yellow fruits—food in plenty for many birds during the next few weeks—and the other, P. angustifolia, of ungainly habit, but generous in the production of its rather large, rich yellow fruits.

Several Pyruses are carrying heavy crops, notably P. purpurea, with crimson fruits; the P. Niedzwetzkyana seedlings, and Pyrus Eleyi, dark crimson. Among fruiting Thorns, Crataegus coccinea, heavily laden with scarlet fruits; C. orientalis, whose large, orange fruits show to advantage among the downy, grey foliage, and C. orientalis var. sanguinea, with crimson fruits, are worthy of attention.

Among the many shrubs and trees whose leaves have assumed rich colouring, mention may be made of Parrotia persica, which never fails to "pass out" in a blaze of orange and scarlet; Pyrus ovoidea, whose every leaf is rich crimson; Spiraea prunifolia, now a broad column of deep bronze; the low-growing Pyrus melanocarpus, with red and purple leaves, and Rhus Cotinus var. atropurpurea, which has changed its foliage very effectively from purple to light shades of yellow, orange and red. Although Quercus coccinea, Knaphill variety, has not yet attained its full autumn beauty, it is already a landmark in Seven Acres, while the crimson stems of Cornus sanguinea, on the pond margin, are also beginning to show to advantage.

Finally, although no blossom is now to be seen in the Heath garden, except a few belated, scattered blooms of Daboecia polifolia, the general effect in this beautifully conceived garden is very intriguing, consisting now of a delightful blending of subdued colouring—the purple hue of the large drifts of Daboecia, the golden-brown, faded flowers of Erica vagans, and the light green of the developing inflorescences of Erica darleyensis and other winter-flowering Heaths, combining to produce a most harmonious effect. *F.*

NOTES FROM GLASNEVIN.

ARISTOLOCHIA GIGANTEA.

THIS handsome stove climber (Fig. 166) was collected in Brazil by the celebrated traveller Von Martius, and was described by him. It is remarkable for the large size of its flowers, the expanded limb being at least nine inches wide and as much in length, divided into two equal, rounded lobes. The colour is reddish-purple when the flowers are fresh. Unlike many of the species, the flowers are pleasantly fragrant. The leaves are heart-shaped, the largest over three inches long and two-and-a-half inches wide. Although lacking the "tail" of A. gigas, and others of the large-flowered section, A. gigantea is more attractive in colour and has the additional attribute of sweet scent. Our plant was acquired from Messrs. L. R. Russell, Ltd., of Richmond. Propagation may be effected by cuttings.

COLCHICUM AUTUMNALE VAR. FLORE PLENO.

Colchicums, for some reason, are not so popular as Crocuses. This is due, no doubt, to the unsightly appearance of the dying leaves at a season when fresh growth is rampant in the garden. It is necessary to plant them where the leaves will not be an eyesore, and there are often secluded corners to be found quite suitable. The variety under notice flowers in October, and this year was particularly good. The flowers are quite double but not clumsy, the colour is lilac, and although not so good in this respect as C. speciosum var. rubrum it is, nevertheless, pleasing so late in the year. The dwarf, single-flowered variety, C. autumnale var. atropurpureum, is deep crimson when fully open, and is the richest coloured of all the Colchicums. A species received from the late Walter Siehe flowered in September. It was sent by him as C. candidum, and is somewhat like C. autumnale, but dwarfer when in flower. The flowers are white, with a faint pink suffusion. When the corms have increased this promises to be an acquisition. Although believed to be a synonym of C. laetum, Siehe's plant seems different, and must await definite determination.

MAGNOLIA GRANDIFLORA.

As a rule this species is more notable as an evergreen than as a flowering shrub. It is fairly often met with growing against a sunny wall, where its handsome leaves and occasional creamy-white flowers are admired. In the open it forms a low, round-headed tree at Glasnevin, and although handsome in foliage, rarely flowers. A native of North America, from North Carolina to Louisiana, it is stated to be found there in the forests, and according to Loudon, grows only in cool, shady places in deep, fertile soil composed of brown mould. In this country, however, it would seem to require all the sun available, and only after a very hot summer such as we have just experienced, does it produce its large, fragrant flowers. Introduced to England apparently about 1737, quite a number of alleged varieties have arisen, among them one known as M. grandiflora var. lanceolata, or exoniensis, reputed to have originated at Exeter. Loudon enumerates several, while Mr. Bean mentions but three, pointing out the impossibility of distinguishing between many of the so-called varieties raised, no doubt, from seeds. Many fine specimens are to be seen in the warmer countries of eastern Europe, and there seeds are produced freely. Two varieties have flowered at Glasnevin this October, viz., M. g. var. Précoce des Nantes (Fig. 165), and M. g. var. ferruginea; the latter, however, scarcely justifies is varietal name, since the rusty-coloured tomentum on the undersurface of the leaves is conspicuous only while they are quite young.

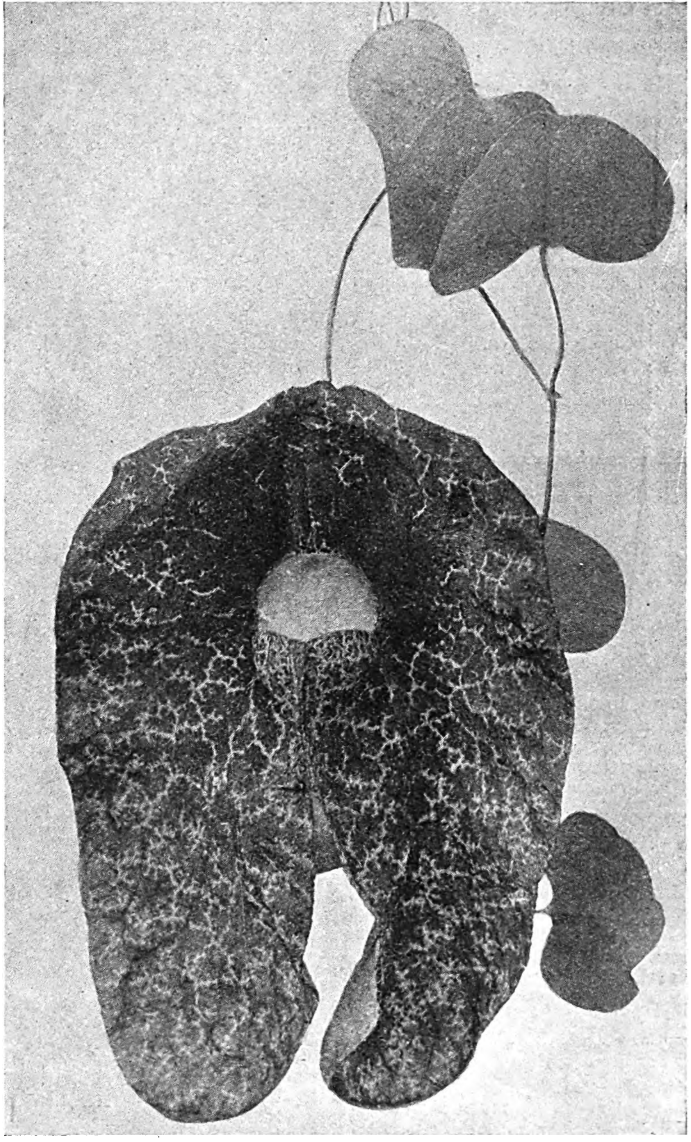

FIG. 166.—ARISTOLOCHIA GIGANTEA.

KNIPHOFIA NELSONII.

The genus Kniphofia, still often called Tritoma, is an exclusively African one, extending from the Cape to Abyssinia. The species are remarkably diverse in habit and vary much in hardiness. All require a deep, very well drained soil and suffer at Glasnevin more from wet winters than from frost. Severe and prolonged frost, however, such as was experienced in Britain last winter, is fatal to most species if unprotected. The species under notice is one of the smaller growers, forming tufts of narrow leaves, the slender flower spikes arising from among them in late summer and autumn. An established clump will produce a large number of spikes of coral-red flowers of great beauty. As the total height when in flower is about two to two-and-a-half feet, the plant may be used in positions where the larger-growing species like K. Uvaria (aloides) would be unsuitable. *J. W. Besant, Glasnevin.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London: or by telephone to Temple Bar. 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXIV.—The Last Round.

On October 15 the weather was as bad as ever. The rain began in the small hours, and when we awoke, it was blowing hard and pouring pitilessly. The coolies, who had been flooded out of their leaf shelters, were shivering with cold, being wet through; in any event they were too scantily clad to be able to keep warm in such a wind, all their fires having been put out. We held a council. Buttercup was in favour of putting off our departure for another day; and I was lothe to abandon Polon—for obviously we could not even go up to the cave on such a day. But the coolies said that if we did not go down immediately, they would not come back for us again. This was more than I dared risk, so with a sinking feeling, I gave the order to retire to Meiliang camp in the valley.

On the way down I collected a number of Rhododendron seeds, including the pale 'Aureum' and the gamboge 'Boothii,' otherwise known as the 'Gamboothii.' In spite of the atrocious weather, the scarlet 'Neriiflorum' was making pathetic efforts to flower again, and several trusses had opened a rheumy red eye. On the lower ridge many Orchids were flowering. The narrow-leafed Cymbidium was in full bloom, hanging out long spikes of purple-spotted, white flowers; the rock Pleione—probably P. maculata—had purple flowers; there were two or three species of Coelogyne, and the yellow Cirrhopetalum previously mentioned. Dendrobium fimbriatum and the big Cymbidium were over—the latter flowers again in April. On the wooded ridge and especially on the steep open face between 6,000 and 4,000 feet, a number of shrubs were in flower, including Luculia gratissima, an Oxyspora, Osbeckia chinensis, Astilbe, and a pale yellow Scrophulariad I had never seen before—perhaps a species of Lindenbergia. The rain continued all day, but it was quite warm in the valley, even in our wet clothes.

October 16, after a shaky start, turned out fine. We dried our clothes and tents in the hot sunshine, and got all the seeds laid out. I prepared to move, and on the following day, accompanied by Hubble and the Gam, set out up the valley for Kaso. It was a cloudless morning, roasting hot, and although we carried very light loads, the overgrown path proved wearisome. We had food for five days, a blanket, and a few warm clothes for the night. We reached Tablekon at one o'clock, and went on across the ravine to the next village, whence the path goes up the ridge to Kaso. Having been refused admission to two huts, I selected the most convenient and planted myself there for the night; no one turned us out.

During the night it began to rain, and by morning the mountains were swathed in mist, and a steady drizzle was falling. I decided to wait a day, and in the afternoon went to the gorge where I had found a solitary bush of the golden Abelia in May, and collected all the fruits there were of it, besides Rhododendron dendricola and the dwarf, bush Hypericum.

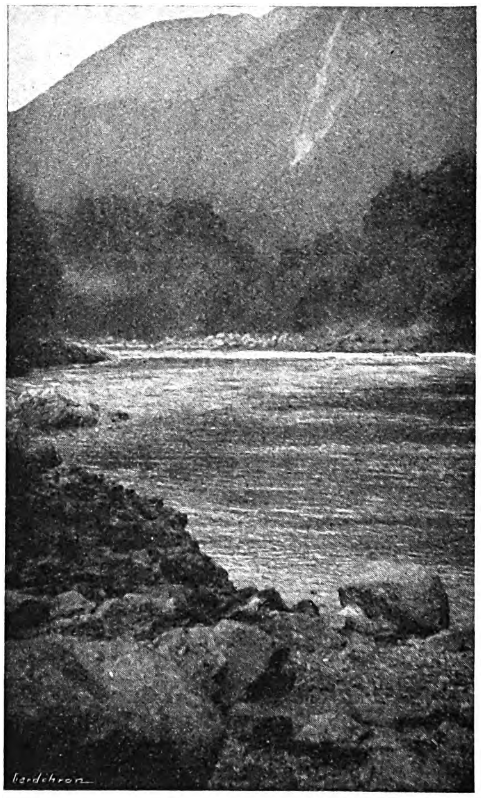

FIG. 167.—THE LOHIT RIVER.

The first event next day was the irruption at an early hour of three noisy young bucks into our hut. I told Hubble to order them out, but he was afraid to do anything, as they were cursing the householder for taking me in. Poor man, he had no choice! I pushed two of the Mishmis out and left the third. I was afrad they might draw their knives, as they were very angry, and the last thing I wanted, when we were so near our goal, was a scrimmage. All things considered, I was glad to get away safely from that village, where I was distinctly unpopular.

We started up the ridge at eight, and the rain began immediately and continued all day. At noon, we reached our old camp, and went on to the big cave for lunch. This cave was large and dry, affording excellent shelter, but it was a long way from the alpine ridge, and I decided to spend the night higher up. So we went on so far as Isopyrum Cliff, where there was a small hollow under the rock; before we got there the Mishmis became frightened at the cold—our altitude now was 11,000 feet—and had snow fallen they would have bolted. But it just continued to rain and rain; we were wet to the skin from pushing through the drenched bushes, and the wind was cold. This alcove at Isopyrum Cliff was a most miserable place. Rain from the sloping roof dripped on to us from a dozen crannies, the wind blew straight in and everything was soaked; there was not even room to lie down at full length, so narrow was the ledge. While the Mishmis were cutting wood and lighting a fire, I collected all the seeds I could find of the cream 'Sikkimensis' Primula, the 'Auriculata,' and P. septemloba, the yield of each being scanty; the capsules of the last named had nearly all been bitten off. Then I went after Rhododendron 'Rock Rose,' but here again there was scarcely one capsule where two flowers had been, and I got very few seeds. 'Rock Rose' grew on a very steep face, which was now slippery with mud and water spread over it in a film; and while searching for capsules my foot slipped, and I shot down the face at terrific speed, tearing my hands badly, but coming to rest without serious injury. We turned in early. It rained all night and by morning the rain had turned to snow. We hardly slept at all, but about three o'clock the fire went out, and it grew bitterly cold. We rose at dawn, very stiff—a grey dawn with the snow slopes of Kaso looming faintly through the thick mist. Quickly I prepared myself for the climb—thick clothing, nailed boots, mittens, and dark goggles. It was useless for the Mishmis to accompany me as they would have been frozen to death, so I told them to pack up and take everything down to the big cave, where I intended to sleep the night; and at eight o'clock I started up the ridge. Immediately after starting I got into the snow, which smothered the Bamboos and Rhododendrons. However, I made excellent progress up the ridge—there was no incentive to loiter, and presently I came to the carmine 'Barbatum' Rhododendron, and secured a few capsules. The next thing wanted was the speckled Nomocharis from Iris Cliff, but to my chagrin, I could not find a single plant of it on the north face. Then I tried the south face, which was more difficult, as the escarpment was high; and here I saw half-a-dozen plants, which produced two caspules between them! And with that I had to be content as I had already wasted a lot of time here; I also collected seeds of the bright red 'Sanguineum' Rhododendron, but the seeds afterwards got mixed with some other species.

In another hour I reached the alpine ridge, having collected seeds of the glowing 'Haematodes' Rhododendron on the way; and now the snow grew rapidly deeper, especially on the steep, sheltered face, where the Rhododendrons were; I collected a little 'Saluenense' and the wash-leather-leafed bush with speckled yellow flowers; and having ascended to close on 13,000 feet, prepared for the worst. A severe snowstorm was raging up here, the wind coming from the north. After digging the first 'Rose of Kaso' out of the snow, and finding that it had not set one capsule of seed, I took stock of the position. It was as clear as day that all the dwarf Rhododendrons must be abandoned; that is to say, the pink 'Anthopogon,' R. repens, 'Rock Rose,' R. campylogynum, and the pink 'Campylogynum,' which was probably R. pumilum. It was also clear that there was no hope of getting Meconopsis paniculata, or the other Meconopsis, or the 'Soldanelloid' Primula, or the 'Muscarioid' Primulas. So far, nothing very serious except the loss of the pink 'Anthopogon.' The question was, could I get 'Rose of Kaso,' the most lovely of all the smaller species? Some large patches of it grew on the very steep face below the ridge, which overhung it.

The long slope was as smooth as glazed china under its mantle of snow, and even the cairn I had built to mark 'Rose of Kaso' was buried. Here was a poser; but if I could cross the gulley, it might be possible to find the plant. However, it was first necessary to traverse across the face, since I could not get down from above; and what had been easy enough in June was distinctly dangerous in October. But the risk must be

DELPHINIUM BORDERS AT THE RAFT, SALE.

run. Leaving the ridge, I scrambled through the snow-bound scrub, and started across that smooth and shining face, kicking steps in the frozen crust as I went, and moving cautiously. Half-way across the worst happened; my foot slipped, and the next second I was flying down the slope in a smother of snow. By a miracle I came to rest fifty feet below, but my nerve was shaken. However, it was impossible to go back, so I went on, and was presently clawing my way up the opposite side of the gulley to where the snow rested on a foundation of scrub Rhododendron. This was pretty safe, and I started climbing more confidently up the steep slope, sinking knee-deep into the soft snow. It seemed quite impossible to find anything here, until suddenly I stood right on a small plant of 'Rose of Kaso' which yielded two capsules; but although I excavated all around the site, I could find no more.

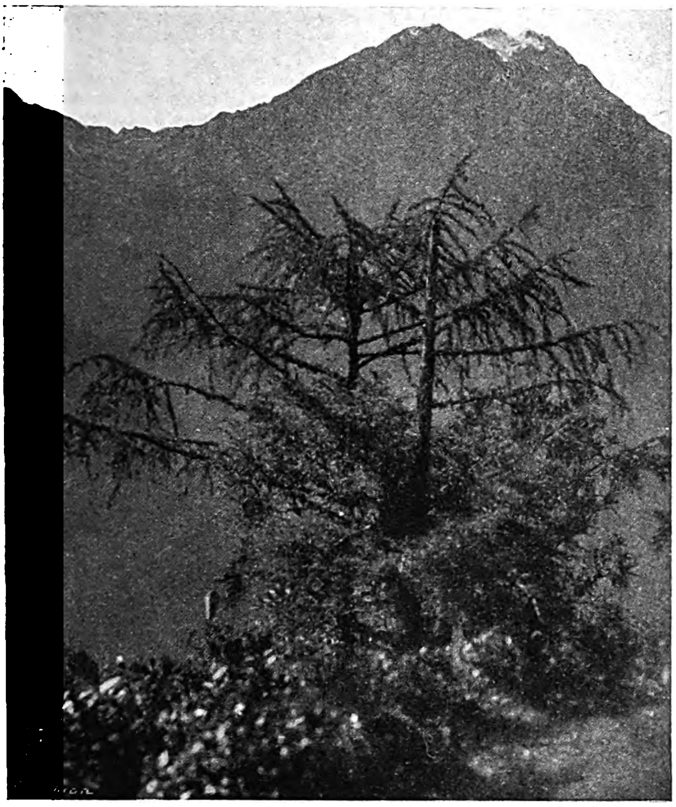

FIG. 168.—LARIX GRIFFITHII.

It became necessary to reach the ridge now at all costs; in the first place, it was late, and in the second, it was bitterly cold standing and digging in the snow, and my fingers were already beginning to show symptoms of frost-bite. I struggled up the slope, climbed the cliff, and at last threw myself down in the snow on the crest of the ridge, exhausted and thoroughly scared. On the cliff I found some plants of the pink Anthopogon, but they had not set seeds. From this point to the summit of Kaso everything was buried under three or four feet of snow, with drifts ten feet deep, and it was both useless and dangerous to prosecute the search further. Turning to the west, I saw that the clouds had broken and were rapidly thinning away; the sun shone out, and all around ranges of snowy mountains were revealed. Soon after dark, I reached the cave, to find a good fire burning and everything snug—a great improvement on the previous night.

After a cold and brilliant night, the 21st was gloriously fine. On the way down the ridge, I collected one truss of the fourth and last 'Barbatum' Rhododendron. Marching all day we reached a hut at dusk, only about three miles from Meiliang camp, and making an early start on the 22nd, I got there in time for breakfast, to find that Buttercup had made all arrangements for going down the valley next day, if necessary. *F. Kingdon Ward.*

APPLES ON METZ PARADISE STOCK.

It is well known that Apple and most other fruit trees, not coming true from seeds or easily from cuttings, require to be grafted on a root or "stock" as it is called. In the early days of fruit culture this stock was usually raised from a seed, such as the Crab or wild Apple, or from the wild Pear for Pears. Very early in history it was found that certain Apples would root from cuttings, and when these were grafted, the graft, and consequently the resulting tree, grew less vigorously and devoted its attention to fruiting rather than to growth.

In Apples, this free-rooting, dwarfing stock was at first thought to be the Apple from the Garden of Eden, and thus the name Paradise was attached to it, and in time all Apples which could be raised from cuttings or layers were also called Paradise, so that the name, first used for a particular variety, became the name of a family—the Paradise Apple stocks.

As their number increased growers realised that there was difference in the dwarfing powers. Some, such as the old French Paradise, gave a tree so small that, except for purposes of ornament, its use was discontinued. At the other extreme were the strong varieties which produced a large tree, so that the choice of the right stock was seen to be of some importance for garden purposes.

The old French Paradise, long used in France, to produce the smallest garden trees, has certain disadvantages, its liability to disease being the worst. The introduction of another strongly-dwarfing Apple stock was therefore desirable, and when the famous nurserymen of Metz, Messrs. Simon Louis Frères, introduced the Metz Paradise stock it was soon tried in France and Germany and approved. Thanks to the well-known trials at the East Malling Research Station, it has been brought prominently to the notice of British growers, and its capacities of dwarfing and early cropping have attracted much attention. Its good points are patent; early production, great freedom in making fruit buds, and early ripening of fruits, all of which are of good size and well developed, make it *par excellence* the stock for small gardens and for the production of choice fruits.

It is indeed a remarkable sight to see a row of cordons, three years old, say, of that impenitent late fruiter, Blenheim Pippin, bearing at this early age almost with the freedom of an Early Victoria. Such a row of cordons, when six feet high, each producing its two dozen or more fruits, would be a feature in any garden, and as it would take less room than a row of Raspberries, it should be possible for many gardeners to have this second string to their bow for the production of the best dessert Apples.

Having worked a large number of varieties on this stock for some years, I find it most suitable for all the choice dessert Apples, especially those of firmer flesh and wood. Soft-fleshed varieties, such as James Grieve, and still more, the soft-wooded Codlins such as Grenadier, Lord Grosvenor, Early Victoria and the like, I find apt to blow out as maidens and two-year-old trees; this, however, is only the nurseryman's trouble.

Another defect from the nurseryman's point of view, however, is that the stock roots slowly and usually requires to stand two years before it can be budded. I do not find, as some do, that budding is less successful than grafting; given good conditions a good "take" of buds can be obtained. The chief criticism of the stock from the gardener's point of view is its lop-sided root-system, which causes it to blow over very easily, and it should always be very firmly staked, as the authorities at East Malling always advise.

After two dry summers, I find that it has a tendency to throw off fruits of some varieties before they have fully coloured. This year, for instance, fruits of Cutler Grieve, that brilliantly scarlet variety, all fell before they had attained anything like their full colour. It would be well, therefore, to proceed carefully in the south in its use for such Apples as Beauty of Bath and James Grieve which have this distressing habit of dropping their fruits before they are ready to be gathered. For all mid and late season Apples, for which I have now used it as a stock, numbering some fifty distinct varieties, I can strongly recommend its use for the smaller forms of trees and we owe a debt both to East Malling for bringing it prominently before English growers, and to the discoverer, Mr. Dieudonné of Metz, who, chancing upon the seedling in a vineyard at Montigny in 1828 had the happy thought of trying it as a stock, and so enabling us to replace the old French Paradise by a successor, which if not the ideal stock, is a great advance on its predecessor, the old French Paradise.

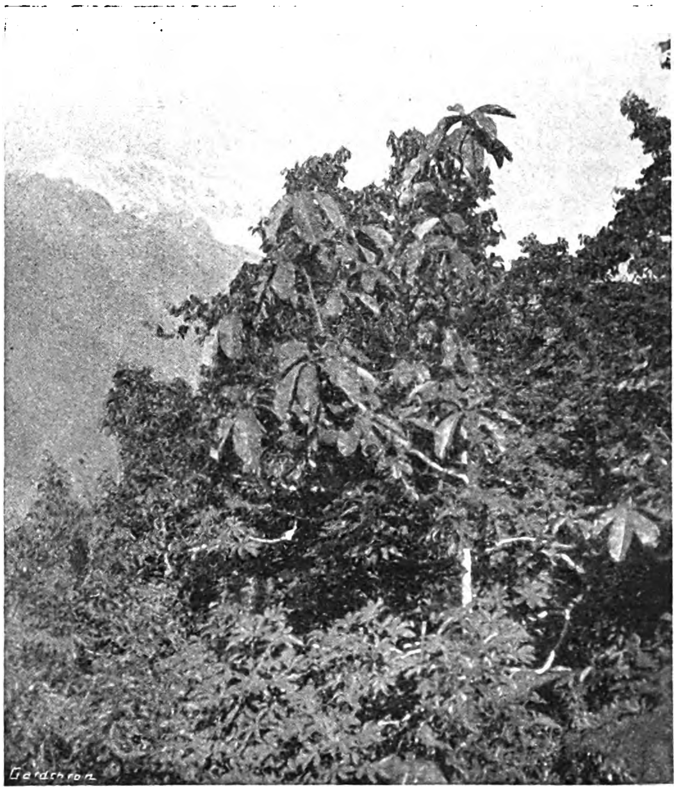

FIG. 169.—MAGNOLIA ROSTRATA.

Of the Apples which I have tested upon it, the following list contains those which can be recommended for cordon or dwarf bushes:—Adams's Pearmain, Allington Pippin, Belle de Boskoop, Blenheim Pippin, Braddick's Nonpareil, Christmas Pearmain, Claygate Pearmain, Cox's Orange Pippin, Duke of Devonshire, Egremont Russet, Ellison's Orange, Golden Delicious, Gravenstein, King of the Pippins, Lady Sudeley, Lord Hindlip, Mother, Orleans Reinette, Pitmaston Pine-Apple, Reinette du Canada, Ribston Pippin, Rival, Rosemary Russet, Sanspareil, S. Edmund's Russet, Superb, and Worcester Pearmain. *Edward A. Bunyard.*

PLANT VARIATIONS.

(*Continued from p.* 324.)

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

Chimaeras.

Perhaps one of the most fundamental conceptions arising out of genetical work in plants has been that of the chimaera.

A chimaera may be defined as a mixture of distinct tissues in the same shoot. On this conception one may have either sectorial or periclinal chimaeras.

Sectorial chimaeras consist of longitudinal stripes of distinct tissue arranged in no regular pattern. They are very unstable, and depend for their perpetuation on the disposition of the growing point. Examples are to be found in many variegated plants, and those which sometimes produce variously coloured and striped petals on the same plant, *e.g.*, some Roses, Pelargoniums, Azaleas, Fuchsias and Chrysanthemums.

Periclinal chimaeras consist of a skin of one tissue enclosing a central core of another tissue which is genetically distinct. They are less liable to vary than sectorial chimaeras. Terminal and axillary buds on a periclinal stem perpetuate the tissue arrangement of the stem on which they are borne. The skin is generally uniform over the whole plant, but may be of different thicknesses in different periclinal chimaeras.

Periclinal and sectorial chimaeras which occur in plants raised from seeds, and not resulting from grafting, are Azalea, Bouvardia, Pelargonium (Zonal, Regal and some of the scented-leaved varieties), Phlox decussata, Rosa, etc., and also in many plants having variegated leaves.

The dual structure of some of these has been demonstrated by means of root-cuttings. A few examples may be cited here, viz., the Regal or Show Pelargonium Madame Thibaut has given several sports, one of which, having pure white flowers, known as Pearl, when propagated by means of root-cuttings will give plants bearing red flowers similar to Madame Thibaut. When the root-sport is again grown from root-cuttings it will come true. This has also been found true with other Regal and scented-leaved varieties of Pelargoniums, and also with Bouvardias.

A Zonal Pelargonium known as Double New Life (Fig. 170), is stated to have originated as a sport from Vesuvius. The flowers are double, but greatly reduced in size, and consist of a large number of small, narrow, red, white and striped, petal-like growths. This plant is imperfect as regards seed production unless it be crossed with pollen from the single-flowered form of Vesuvius, when the offspring will produce flowers indistinguishable from that variety. P. Double New Life will frequently produce normal, red, single flowers (Fig. 171) among the double ones on some of the trusses, and when grown from root-cuttings, the plant will give normal single, red flowers.

Another Zonal Pelargonium, Flower of Spring, a variegated variety, having white margins (Fig. 172), *i.e.*, white skin, enclosing a green core (white-over-green), frequently produces completely green-leaved shoots, and will also give a reversed form of variegation, wherein the core of the plant is white, enclosed in a green skin (green-over-white). When the typical Flower of Spring is propagated from root-cuttings it will produce green-leaved plants, because the core is green.

If the reversed form, *i.e.*, green-over-white, is grown from root-cuttings it produces white-leaved shoots, because the core of the plant is white. These white-leaved shoots will only live for a short time, owing to the absence of chlorophyll.

Root-cuttings raised from the entirely green-leaved plants will be wholly green. This behaviour of variegated-leaved plants holds good for many varieties that have been tested here. For other examples see under 'Variegation."

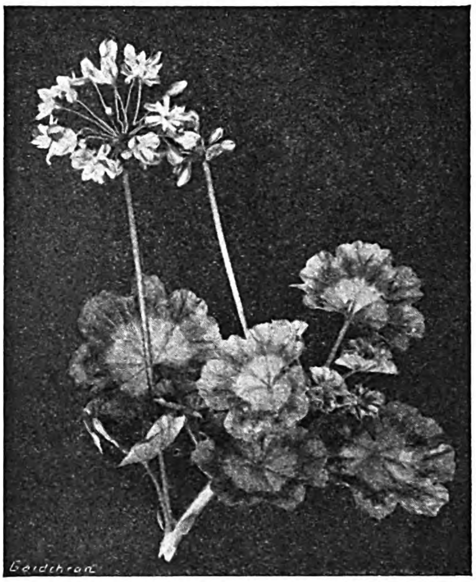

FIG. 170.—PELARGONIUM DOUBLE NEW LIFE.

Somatic segregation of chimaeras, both from root-cuttings and as bud sports, is worthy of special note.

It is well-known to horticulturists that certain plants, propagated from buds formed directly on the roots, do not come true to the parental form. The buds formed on roots have a deeply seated or endogenous origin; hence, in a periclinal chimaera, they consist solely of the tissue composing the core of the plant.

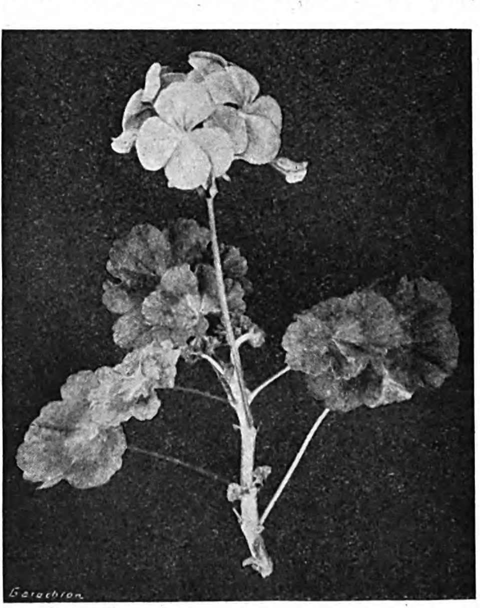

FIG. 171.—PELARGONIUM DOUBLE NEW LIFE WITH SINGLE FLOWERS.

It may be of interest to describe the method by which plants are propagated by root-cuttings, showing the changes that have been brought about in this way.

Quite a number of plants are capable of being propagated by means of root-cuttings, but by no means any or every plant, nor do all plants grown from roots give something different to the parent; in fact, the majority come true. At Merton we have tried many hundreds of species and varieties fairly representative of all the flowering plants and only a small percentage of those tried was successful.

The writer, after many trials and by several methods, found that by cutting back a plant nearly close to the level of the soil and inverting the whole root system in a pot of soil, exposing the roots to light and air, a number of plants, which formerly resisted all attempts at root propagation, now produced buds. It is possible that the period of the year and the state of the plant, *i.e.*, whether it is in active growth or approaching the season of its rest, or just before the plant commences to renew its growth, and also the degree of humidity and the temperature of the propagating house or frame, have some effect on the success or failure of this method of propagation.

Many garden varieties of Pelargonium, Bouvardia, Phlox decussata, etc., have originated in this way. Such sports are a source of much confusion of names in gardens, as the same kind of root-sport has made its appearance in different gardens and at different times. Such sports have been given names to distinguish them from existing varieties, hence there are more names than distinct sorts. *A. Hosking, Garden Superintendent, John Innes Horticultural Institute, Merton, Surrey.*

(*To be continued*).

THE GENUS PRIMULA.

(*Continued from p.* 345.)

sinensis (Lindl.). Chinese P. (Sinensis).

This deservedly popular plant, which needs no description, was introduced into this country in 1820 by Captain Rawes, who obtained it from the gardens of Canton, where it had apparently been cultivated for a great number of years. It has never been collected in a wild state, and is thought by some authorities to be a hybrid of unknown parentage. P. calciphila, Hutch., was at first thought to be the wild form, but is now considered a valid and distinct species. P. sinensis, Lindl., which, to follow the strict rules of priority in nomenclature, should be known as P. praenitens Ker.-Gawl. is figured under that name in the *Botanical Register* for 1821, t. 539, also in the *Botanical Magazine* for 1825, t. 2564, as P. sinensis, Lindl., to which readers are referred for good coloured illustrations of the plant as first imported.

sinodenticulata (Balf. f.). Chinese Toothed P. (Denticulata).

A robust sub-species of P. denticulata, with a thick rootstock clothed with the dry remains of the previous seasons' foliage. The plant forms scaly, whitish resting buds which eventually turn rusty-brown, and from these the rosettes of oblong, egg-shaped-oblong or oblong-spathulate, blunt, membranous leaves develop. They measure about three inches in length at flowering time and when quite mature are six inches or more long and taper to a strap-shaped stalk; margins slightly reflexed, sinuate and at times obscurely toothed; both surfaces covered with very minute down, the principal veins being red. Flower stem robust, about nine inches tall, densely coated with yellow meal towards the tip and bearing a globose umbel of numerous, purple, white-eyed blossoms on rigid, more or less mealy stalks about a quarter-of-an-inch long. Corolla about five-eighths-of-an-inch long, with egg-shaped, deeply divided segments; tube cylindrical, nearly twice as long as the calyx. Flowers in May.

Grows in moist alpine pastures on the Tali range, in western Yunnan, western China.

Culture: As for P. denticulata.

SINOLISTERI (Balf. f). Lister's Chinese P.
(Obconica).

This pretty, deciduous perennial is a sub-species of P. obconica. It has a woody, branching rootstock clothed with the dried remains of previous seasons' foliage. The numerous tufts of glaucous leaves have nearly circular blades three-quarters- to one-and-a-half inch across, blunt at the tip, heart-shaped at the base, borne on slender, rigid, downy stalks one-and-a-half inch to two-and-a-half inches long; margins lobed, lobes pointed or blunt, furnished with sharp teeth; minutely hairy above, downy below, hairs non-irritant. Flower stem two to eight inches tall, slender, downy, bearing an umbel of two to eight white, pale rose, or lavender-rose, green-eyed, fragrant blossoms. Corolla about three-quarters-of-an-inch across, with heart-shaped, notched lobes; tube about three-eighths-of-an-inch long with a ring in the mouth. Flowers in May and June. Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Introduced in 1909.

Grows in dry, rocky pastures or on the moist ledges of shady cliffs on the Tali range, in north-western Yunnan, at 7,000 to 10,000 feet above sea-level.

Culture: As for P. Forbesii.

SINOMOLLIS (Balf. f.). Chinese Downy P.
(Cortusoides).

A handsome, herbaceous, perennial sub-species of P. cinerascens, Fr., with a fleshy rootstock covered with scales. The leaves are produced in a rather large tuft and have elliptic-heart-shaped or sub-rotund-heart-shaped blades about four inches across, on densely hairy stalks about two inches long, dilated at the base; margins sub-revolute, with somewhat sinuate lobes furnished with curved teeth; upper surface shortly downy; underside intricately veined and hairy. Flower stems numerous, up to twenty inches tall, slender, downy, often decumbent after flowering, bearing numerous superposed umbels of four to six fragrant blossoms of a bright rose colour with a yellow eye, or bright magenta-rose with a greenish-white eye; they are sub-oblique, on horizontal, thread-like stalks about half-an-inch long. Corolla about three-quarters-of-an-inch across, segments broadly heart-shaped, deeply cleft, lobes entire; tube about three-eighths-of-an-inch long, cylindrical, with a ten-lobed ring in the mouth. Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Flowers in April and May.

Grows in somewhat dry situations in evergreen and deciduous forests, on the western side of the Salween valley, in Yunnan, western China, at 7,000 to 8,000 feet above sea-level. Introduced in 1913.

Var. alba, Balf. f., has almost white flowers with a deep rose-coloured eye; grows in pasture lands on hills to the east of Tengyueh, in Yunnan, at about 6,000 feet.

Culture: As for P. mollis.

SINONIVALIS (Balf. f.). Chinese Snowy P.
(Nivales).

A handsome, deciduous perennial species, with short, scaly resting buds coated with white meal, from which tufts of thin, Papyrus-like leaves about six inches long are produced; the narrowly egg-shaped blades are usually rounded at the tip and taper to an indistinct stalk; margins edged with small, regular, rounded teeth; upper surface more or less smooth, underside sparsely clothed with minute, meal-producing, glandular hairs. Flower stem six to nine inches tall, stout, bearing a many-flowered umbel of bluish-purple blossoms on short, slender stalks. Flowers in July.

Grows in moist, open, alpine pastures on the mountains of the Mekong-Salween divide, in western, north-western Yunnan.

Culture: Good rich loam in a moist, open spot should suit it.

SINOPLANTAGINEA (Balf. f.). Chinese Plantain P.
(Nivales).

A handsome, deciduous, perennial species with large, reddish, membranous, scale-like resting buds about two inches long, which are persistent and sheath the base of the tuft of lance-shaped, pointed leaves, which taper to membranously winged stalks; margins furnished with obscure, rounded teeth; upper surface more or less smooth, underside slightly coated with yellow meal. Flower stem six to twelve inches tall, stout, sparsely coated with golden-yellow meal and bearing an umbel of several fragrant, deep bluish-purple blossoms; the bracts are also deep purple. Flowers in June and July. In cultivation in 1925.

Grows in open, moist, stony alpine pastures on mountains east of Yunging, in south-western Szechuan, at 14,000 feet above sea-level; also in north-western Yunnan, on Beimashan.

Culture: Grow it in good, rich, somewhat heavy, fibrous loam in an open spot well supplied with water when the plant is in growth.

SINOPURPUREA (Balf. f.). Chinese Purple P.
(Nivales).

A very beautiful, perennial species with a rosette of broadly lance-shaped, rather pointed, thin leaves from four to eight inches long, gradually tapering into winged stalks; margins furnished with sharp, curved teeth; upper surface smooth, underside coated with yellow meal. Flower stems stout, four to fifteen inches tall, bearing an umbel of six to twenty deep violet or deep rose-lavender blossoms on slightly mealy, curved stalks; at times a second umbel or whorl of a fewer flowers is produced below the terminal one in strong specimens. Corolla about one-and-a-quarter inch across, with spreading, broadly elliptic or rounded lobes; tube funnel-shaped upwards, cylindrical below, about half-an-inch long.

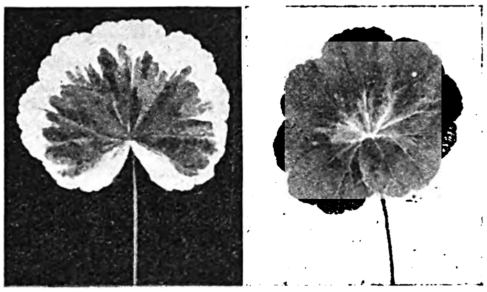

FIG. 172.—PELARGONIUM FLOWER OF SPRING
Showing marginal and central variegation.

Grows in damp, open situations, usually in rich soil, on the mountains of Yunnan, western China; also in south-eastern Tibet at 14,000 to 15,000 feet above sea-level. Introduced in 1915. *Bot. Mag.*, t. 8,777.

Culture: Plant it in good fibrous loam, leaf-soil and sand in a cool, damp spot; it is not a long-lived plant, but is quite hardy.

SIPHONANTHA (W. W. Sm.). Siphon-flowered P.
(Soldanelloidae).

A pretty, somewhat tufted, perennial species with broadly lance-shaped, blunt or rather pointed, thin leaves, one-and-a-half inch to two-and-a-half inches long, narrowed to a short, broad, winged stalk half-an-inch to one inch long; margins furnished with irregular sinuate teeth edged with minute hairs; both surfaces green, covered with minute, stiff, meal-producing, glandular hairs; underside with the mid-rib and nerves furnished with long, white hairs. Flower stem eight to ten inches tall, covered with minute hairs and coated with meal at the tip only; the pale violet, deflexed blossoms are borne in an umbel of four to five and are everywhere covered with minute glandular hairs. Corolla about five-eighths-of-an-inch long, elongate, with short, narrowly-oblong segments furnished with two or three sharp, irregular teeth at the tip; tube cylindrical below, inflated upwards, about one-eighth of-an-inch long.

Grows on slopes and banks, usually fully exposed, in the Scinghku valley in north-eastern Upper Burma, at about 11,000 feet above sea-level.

Culture: It should succeed in good, gritty, friable loam in a damp spot, with protection from wet in winter.

SMITHIANA (Craib). Smith's P.
(Candelabra).

A handsome, deciduous, perennial species with a rosette or tuft of thin, papery, oblong, lance-shaped or rarely broadly lance-shaped leaves, rounded at the tip, tapering to a more or less distinctly winged stalk, in all from three to five inches long; margins furnished with sharp teeth; both surfaces usually more or less smooth, underside at times sparsely coated with yellow meal. Flower stem stout, smooth, up to nearly two feet in height, bearing one or two superposed umbels of yellow blossoms on slender stalks about half-an-inch long. Corolla three-quarters-of-an-inch to one inch across, with five heart-shaped lobes; tube about three-eighths-of-an-inch long with a ring in the throat. In cultivation in 1920.

Grows in damp situations in the Chumbi valley, in the Sikkim Himalayas.

Culture: Good rich, fibrous loam, in an open, sunny spot, well supplied with water when the plant is in growth, are the conditions indicated.

SOLDANELLOIDES (Watt). Soldanella P.
(Soldanelloidae).

A very beautiful, perennial species of minute proportions, best treated as a biennial in cultivation. It produces rosettes of oval, blunt, deeply pinnatifid leaves, wedge-shaped at the base, with rather long stalks, in all from a quarter- to half-an-inch long; both surfaces smooth, non-mealy. Flower stem slender, hair-like, three-quarters to one-and-a-half inch tall, bearing a solitary, nodding, white blossom about five-eighths-of-an-inch across. Corolla broadly funnel-shaped, with short, coarsely-toothed lobes; tube dilated upwards, about as long as the calyx. *Pax. Prim.*, Fig. 24 c.

Grows in damp, rocky places in the Kankola Pass, in Sikkim, also at Patangla, in Bhutan, eastern Himalayas, at 15,000 feet above sea-level, frequently flowering at the edge of melting snow.

Culture: As for P. Reidii.

SONCHIFOLIA (Franch.). Sow Thistle-leaved P.
(Petiolaris-Sonchifolia).

A very beautiful, perennial species whose flower stems rise from a number of large, broadly oval scales which are covered with rich orange-coloured meal. The Papyrus-like leaves have oblong, or egg-shaped-oblong, blunt blades from six to eight inches long, slightly narrowed at the base; margins furnished with sinuate, sharp, broadly triangular teeth or lobes; both surfaces dotted with elevated glands and at times sparsely mealy towards the base. Flower stem three to nine inches tall, stout, smooth, or covered with minute scales, or at times sparsely mealy, bearing an umbel of four to ten rather crowded, erect, bright blue or deep indigo-coloured blossoms with a pale yellowish-white or yellow eye. Corolla nearly one-and-a-quarter inch across, with broadly egg-shaped, shallowly notched, irregularly and sharply-toothed lobes; tube about five-eighths-of-an-inch long, dilated upwards. Flowers from May to July. *Gard. Chron.*, 1910, Vol. XLVII, p. 58, Fig. 35.

Grows in moist, alpine meadows, at times in shade, frequently flowering at the edge of the melting show in the Tali and Lichiang ranges of Yunnan, western China, at 11,000 to 14,000 feet above sea-level.

Culture: Fibrous peat and gritty, calcareous loam, well supplied with moisture when in growth, with protection from damp in winter, are the conditions indicated. *A. W. Darnell.*

(*To be continued*).

GRADING OF WARE POTATOS.

There is, as yet, no standard definition of a marketable sample of ware Potatos. In view of the variations which occur in practice in regard to the proportion of diseased or damaged tubers, and of earth and other extraneous matter, in commercial samples, it is desirable that a standard definition should be provided in the interests of producers, distributors and consumers.

The Minister of Agriculture and Fisheries has, therefore, made draft regulations[*] under the Agricultural Produce (Grading and Marketing) Act, 1928, prescribing and defining grade designations for voluntary use in the trade. These have been demonstrated by the Ministry of Agriculture during the past year at a number of agricultural shows throughout the country. They provide for variations in the size *i.e.*, minimum diameter of the tubers as between one grade and another, but not for a common standard of dressing as regards disease, damage dirt, and so forth.

Owing partly to differences in public taste, and partly to the difficulty in defining cooking quality, no provision is being made, at the moment, for the use of the National Mark on graded consignments. It is believed, however, that even without the National Mark, the existence of a statutory standard of dressing should be as beneficial to the Potato industry of this country as it has proved to be elsewhere, and that, in time, such a standard will work its way into the trade on its merits.

At present good and bad samples are marketed under the same description. By using the statutory grade designations, growers will be able to guarantee their standard of dressing, which should go some way towards securing them from the competition of poorly dressed lots. Merchants, both wholesale and retail, and public or private institutions, accustomed to buying large supplies, should find the grades helpful.

The extensive use of these grades in conjunction with the excellent quality of this year's crop would probably help to stimulate the demand for home-grown Potatos, and would be an obvious and proper departure from the present condition of informality and uncertainty. Appended is a copy of the schedule embodying the draft grade designations and definitions.

SCHEDULE FOR GRADING WARE POTATOS.

Grade Designation.	DEFINITIONS OF QUALITY.						
	General.	Applicable to single tubers.	Applicable to Quantities.				
			Tolerances.				
		Size (Minimum diameter).	Conformity to Variety, etc.	Undersize or Oversize.	Disease, Damage, etc.*	Earth and/or Extraneous Matter.	Maximum aggregate of all defects under Cols. 5, 6 and 7.
1	2	3	4	5	6	7	8
E. and W. No. 1. Size.	Reasonably clean, healthy Potatos, free from serious defect and suitable for human consumption.	†‡1¾ in.	At least 95 per cent., by count, must conform to the variety as, and when, specified, and to the type of soil on which grown, where such is declared.	Not more than 3 per cent. of the total weight may pass through a riddle or sieve having a square mesh of the minimum size specified (in Col. 3) for the grade, and included in this, not more than 0·5 per cent. of the total weight may pass through a 1-in. mesh. Potatos which exceed 3¼ ins. in their smallest diameter shall be excluded. Otherwise in regard to size, the Potatos shall be as grown.	Not more than 3 per cent. of the total weight may consist of appreciably diseased, damaged, or unsightly Potatos, and included in this amount not more than 0·25% of the total weight may be obviously affected with soft rot.	Not more than 4 per cent. may be present in Potatos loaded up to November 1 in the year of harvesting and 2 per cent. after that date; the percentage to be calculated on the net weight of screened Potatos.	5 per cent. of the total weight.
E. and W. No. 2 Size.		1⅝ in.					
E. and W. No. 3 Size.		1½ in.					

* (i) Any disease or defect, the presence of which may be established by cutting open the Potato, shall be taken into account, and Potatos having worm- or slug-holes penetrating into the flesh shall be regarded as damaged.
(ii) Potatos affected by superficial disease or damage shall not be regarded as diseased or damaged unless more than one-tenth of the surface is so affected.
(iii) A Potato shall only be regarded as being obviously affected with the soft rot if, at the time of inspection, it is squashy and/or the surface is at some part distinctly broken or wet owing to disease.

† When the Potatos have been passed over a riddle of greater mesh than 1¾ in., the minimum size may, at the seller's discretion, be appended to the grade name, *e.g.*, "Special (2 in.)."

‡ As measured clear within the bounds of the mesh.

HOME CORRESPONDENCE.

Bees and Fruits.—I noted with interest the observations of your correspondent, Mr. C. Morris, in your issue of October 19, p. 309, relating to damage to Peaches and Plums by bees during the past dry summer. Here, at Swanley, the damage to the Apple and Pear crops has been extensive, particularly on the variety James Grieve. Numerous hives are kept in our plantations, and throughout the drought, which was unbroken here for months, the bees seemed unable to obtain enough moisture, even when water was provided in trays, and they early turned their attentions to Pears, Plums, and in particular, to Apples. However, as the bee cannot bite like the wasp, the Apple skin had first to be punctured before the bees could feed, and so far as I could perceive this initial injury was caused by earwigs which infested the trees and fruits. The fact that earwigs are usually found in the stalk cavity or between a pair of fruits would account for the bees attacking the stalk end of the Apple first. Many bees were found in the fruits or in the boxes days after the fruits were picked, and merely returned again to the feast when disturbed by grading operations. Jays have been troublesome, and no doubt the bees followed them in many cases. Wasps have been almost entirely absent, and it is the first season I remember in which Plum picking was completed without their greedy and often uncomfortable attentions. *Eric W. Hobbes, Horticultural College, Swanley, Kent.*

——I was very interested in the observations of Mr. C. Morris on the bees attacking fruits (p. 309), as this year I have had the same experience for the first time, especially with Plums and Peaches. When going to gather Victoria Plums I found very few wasps, but a great number of honey bees, while Peaches on an outside wall were badly attacked by bees, which completely spoiled a great many fruits, but hardly a wasp was to be seen. We have been very free from wasps, having found (and destroyed) only one nest, whereas last year I destroyed over eighty nests. What I would like to know is, if it had been an ordinary season for wasps, would they have kept bees away from the fruits? *F. Akers, Hatchlands, Guildford.*

Odontospermum maritimum.—(*Gard. Chron.* October 10, 1929).—I brought this plant back from Majorica, where it covers the low rocks on the shore near Palma. We have always kept it going, although it is a difficult plant to propagate, and is not hardy. Recently, I saw a much stronger form under the name of Asterias maritimus, growing in the rock work in front of Mr. Cheal's house in his nursery at Crawley. This plant, which is much larger in all its parts, is very easy to propagate, and survives most winters. It flowers from April until November, and the great, golden-yellow flowers, which lie flat on the ground, keep open, unlike Gazanias, in the dullest weather. To-day, October 19, six plants are carrying twenty-four flowers. *William Lawrence, Burford.*

Dahlias.—Among the several sections of Dahlias now recognised by florists, few, if any, have grown so much in favour with the general public as the Star and the Collarette groups. And this favouritism is not to be wondered at, seeing how handsomely these two classes lend themselves to decorative work—both in the garden and in the home. Popularity is, however, by no means confined to these Dahlias, for each type has so progressed in all its features under the hand of the specialist as to have its own particular admirers. The improved habit of the Dahlia is quite remarkable, the best varieties no longer hiding their flowers among the foliage, nor yet hanging down their heads. More varied and richer colourings in the flowers greet us in every class, while a vastly freer-flowering nature is found in all sections. There remains, however, one very weak spot in the make-up of the Dahlia plant. It too easily falls a prey to the first frost—which so often comes when the plants are making a beautiful display. Would that the leafage and flower of this easily-grown, good subject were less susceptible to such early disaster! Few sights are sadder to the garden lover than a blackened Dahlia border in early September, while no sight is more pleasing than the same plants gay with flowers in mid-October, as they were this year. *C. Turner.*

Grape Classes at R.H.S. Autumn Fruit Show.—As an old exhibitor and judge of Grapes, I am not quite in agreement with *Sussex Exhibitor* in his suggested restrictions in Grape classes at the R.H.S. Fruit Show (p. 331). Certainly, any restriction other than what has already been in operation would be difficult to make under existing rules. Exhibitors of four varieties of Grapes (Class 3) may not exhibit in Class 4 for two varieties. A similar restriction is in force both at Shrewsbury and Southport. But I am strongly of the opinion that all classes for distinct varieties should be open, for all competitors meet on equal ground, as there is certainly no logical reason why an exhibitor who can only stage one or possibly two varieties may not be as able a cultivator as one who can stage half-a-dozen varieties. Certainly visitors would like to see each particular variety staged in its best possible form. Further, a large garden with a considerable staff does not always mean that a great variety of Grapes is cultivated. May I cite my own case. Here we have a fairly large kitchen garden with a considerable staff—because we have a large household to supply—but we rely on two varieties of Grapes for so long a period as possible because these are what my employer appreciates most. When, some years ago, I had charge of a much smaller garden, with a considerably smaller staff, I grew and exhibited the best Grapes I ever staged; possibly this was because, with less to look after, I could give more direct personal attention to their requirements. My advice to *Sussex Exhibitor* is to put his best efforts into the cultivation of the variety or varieties which are likely to be at their best in October and when, someday, he wins, he will be much more satisfied than if some new restrictions were enforced to make his task easier. May I suggest that *Sussex Exhibitor* turns to the vegetable section of the schedule to which he refers, and notes the restrictions only apply to the collections; all single dishes for kinds or varieties of vegetables are open, even to the exhibitor of the largest collections. *W. H. W., Worcester.*

[*] Agricultural Produce (Grading) (Potatos) Regulations, 1929. Obtainable from H.M. Stationery Office, Adastral House, Kingsway, London, W.C.2.

The Need of Education for Gardeners.—A remarkably thoughtful and helpful communication appeared in your issue of October 26 under the above title from the pen of Mr. M. G. Kennedy-Bell. The subject has interested me for a very long number of years. I well remember when I started to learn the practical side of my business, I lodged with a foreman nursery-gardener who bought every Saturday *The Gardeners' Chronicle* and *The Garden*. That took 1s. per week out of his hard-earned wage, which would not be more than £2 per week. I had the use of these journals and formed a taste for gardening literature which remains to this day. I state that case as an example, and I wish it were more followed to-day, but things have changed since then. In those days gardeners were "passing rich" on forty shillings a week. If in private service with that wage, and a free house, and no rates and taxes, with coal and light, and sometimes milk, with fruit and vegetables and Potatos in season and in reason, he was mighty well off; not to mention a new suit of clothes once a year, or its equivalent from his nurserymen. Such gifts were legal in those days, but not now. How is it to-day? It would require nearly three times that old salary to make a man feel as well off—but the jobs are not there to-day. Since 1914, large-scale private gardening has disappeared to a great extent. In the summer of 1915, I remember the late Mr. Arthur W. Sutton told me how hardly his firm and others who were favoured with the business of great establishments had suffered. I will not mention the figures he gave, they more than proved his case. Since the war ended the position has not much improved. Hundreds, perhaps a thousand or more, private gardens have been let as market gardens, and the expenditure on most others has been largely cut down, therefore even the modest, although comfortable inducements of long ago to become gardeners do not exist to-day. The war has changed everything and everyone's outlook. When I started my gardening career we had to work from 6 a.m. to 6 p.m. every day, except Saturdays, and it was a great concession to cease at four or five on that day. I remember when most other tradesmen got a fifty-one hours week gardeners had no concession except the Saturday afternoon from two o'clock. Hours are better to-day, but wages are still low, and the resultant real trouble is that the right sort of lads, unless they have a bent, or love, for gardening will not enter it. A friend of mine who was brought up on a small farm in the north of Scotland, and who now occupies a University Chair, had a beginning like my own and he recently told me he had been to visit his native village. All the young men and lads now had bicycles, and so soon as work was done and they had got some food and changed clothing, they were off to the adjoining town, three or four evenings a week, and invariably for the whole Saturday afternoon and evening—so different from his early experiences. We agreed this was a war result, and the hands of the clock would not be turned back. Country life does not to-day appeal to the average modern lad, neither here nor abroad. Australia has some 6,000,000 of a population, half of whom are crowded into the cities! Of the lads who now enter gardening in any of its numerous branches, I estimate ten per cent. do so because they are interested—the ardour of a few of these cools after a trial, but that loss is made up by a few of the ninety per cent. who get interested. The problem of education in horticulture, therefore, really becomes one for those who make up my ten per cent., and here I thoroughly agree with Mr. Kennedy-Bell. These lads will grasp the opportunities presented to them and will get more and more interested in the literature, science and practice of their profession, and will get the plums that are going. They will not all rise to the very top, but the positions at the top will be filled by some of them. My friend and neighbour, Professor Wright Smith, tells me that there are always openings, a few at home and numbers abroad, for young, keen men with the right training and experience. On my own desk at this moment I have letters asking if I can recommend for positions in the United States three young men trained in plant breeding and who have a good practical background. I am afraid I cannot. The practical background required is that experience which enables one to exercise a real flair for the good things produced by cross-fertilisation, which will appeal to the public and be a commercial success. I know I run a great danger of being castigated by some of my most intimate friends for postulating this, but I write of what I know and testify of what I have seen. I can illustrate this by an example from the Potato world, the application of which is the same in the floral world. In this century the two great, successful raisers of new Potatos have been Findlay and Mackelvie. Mr. Findlay had, and Mr. Mackelvie has, for he is fortunately still with us, a sort of second sight, otherwise a power of discernment necessary to pick out from tens of thousands of seedlings the units which are to make good, and to suit a world waiting for them. Some seem to be endowed by nature with this power of selection, others acquire it by long years of training and experience, and that, I think, is what my American friends call "a background." *William Cuthbertson, Duddingston, Edinburgh.*

Lonicera nitida.—In his article on Lonicera nitida, *L. C.* (p. 322) is certainly at fault in describing this evergreen, shrubby Honeysuckle as suitable for growing in mild localities only. Last winter severely tested the hardiness of many shrubs, but a L. nitida hedge here came through 28° of frost unscathed, and hundreds of thousands of this species, growing in one of the most exposed positions it is possible to imagine, were also untouched. He also writes of it attaining an ultimate height of three to four feet in this country, but plants have been measured up to nearly seven feet! Undoubtedly L. nitida is the ideal shrub for a close evergreen hedge, and in a very few years will be planted in preference to Ligustrum ovalifolium. Ligustrum Prattii, introduced by Wilson in 1908, has also been tried as a hedge plant, but it has not the graceful appearance of Lonicera nitida, nor is it so fast growing, and after seeing the two plants growing side by side it is easy to perceive why the latter is so deservedly popular. *H. A. P., Brampton, Hunts.*

Mr. Allan Falconer.—Many readers of *The Gardeners' Chronicle* will learn with surprise and some regret, that Mr. A. Falconer, who has been for several years the keen grower at the Cheadle Royal Hospital, is relinquishing that post to take up the position of Parks Superintendent to the Ashton-under-Lyme and Stalybridge Corporations on November 16. Every one of his friends will wish him every success in his new sphere of operations, and will regret that, leaving Cheadle, he will be a possible loss to competitive horticulture in the show tents. Mr. Falconer will be remembered by the many as a clever and consistent exhibitor at numerous big shows, in which undertaking he always proved himself a keen enthusiast and excellent sportsman, whether in winning or in defeat. I sincerely hope that he will still be seen at many shows, and if not as a competitor, then I hope that every use will be made of his services as a keen and competent judge. *E. B.*

Clematis integrifolia.—I was very interested to read the remarks on this plant by Mr. S. Arnott, on page 303, and especially with regard to C. integrifolia var. Durandii. A few weeks ago I was travelling in Holland, and while in the Boskoop district I happened to go into the flower auction market there, and I was particularly struck by some particularly fine bunches of cut Clematis flowers. The bunches consisted of about five sprays, and the blossoms were of a very attractive shade of purplish-violet, and slightly smaller in size than those of C. Jackmanii. The bidding for this subject was very keen, and some good prices were realised. Upon making inquiries, I was told that the variety was Clematis integrifolia var. Durandii; it is certainly an excellent cut flower subject and much in demand on the Continent. It is chiefly used for table decoration, and large consignments are sent daily from Boskoop and district to Rotterdam, Amsterdam and Brussels. I was told that a wholesale flower grower in the Boskoop district found this one subject so remunerative that he grew it to the exclusion of all else! *K. Therkildsen, Southport.*

Good Dessert Plums for Market Growers.—*Market Grower*, in his excellent notes on page 310, refers to the great demand for good dessert Plums, and then writes that: "The true dessert Plums are all stated to be shy bearers." This idea—which seems to prevail among many growers—I believe to be entirely erroneous, and is probably due to the behaviour of isolated trees, or blocks, planted without due regard to providing suitable pollenators. I venture, therefore, to name a few varieties which I have found from experience to be heavy and regular croppers. I planted Jefferson twenty years ago in a mixed plantation, thinking that it might possibly succeed as a standard, but not being very sanguine on that point. To my surprise Jefferson has proved to be the most successful variety in that plantation. It has cropped very heavily and regularly, and high prices have been obtained for all the fruits. During recent years, I have recommended this variety to many market growers, and in each case the results have been good. Oullins Golden is another Plum of fine quality and appearance which makes a sturdy tree, and crops heavily. If packed in punnets or 4-lb. chips, high prices are always obtained for the fruits. Count Althann's Gage is a fine reddish-purple fruited-variety with a free stone. It does not appear to be well-known, or it would certainly be more widely cultivated. It produces heavy and regular crops, and is worthy of the attention of all market growers. Denniston's Superb produces fruits of medium size, is a prodigious cropper, and seldom fails. It makes a fine tree, and succeeds in most districts. Heron, which has attractive fruits, is usually catalogued as a culinary variety, but is really excellent for dessert, being richer in flavour than Victoria. It crops well and comes in just after Czar. Growers in the Evesham district think highly of this variety. The following new varieties raised by Messrs. Laxton Bros., should certainly be tested on a small scale by all market growers on the look-out for profitable dessert Plums:—Goldfinch (Early Transparent Gage × Jefferson), Bountiful (Red Magnum Bonum × Victoria), Delicious (Coe's Golden Drop × Pond's Seedling), and Utility (Jefferson × Peach Plum). *H. Dunkin, Warwick.*

FOREIGN CORRESPONDENCE.

TOMATO HETEROSIS.

I take the liberty of sending you a few observations concerning Tomato Heterosis, listed in Benary's seed catalogue, and quoted in your issue of October 19, p. 311. This Tomato has been tried this summer by various growers in the neighbourhood, both in and out-of-doors, and has, in some respects, fulfilled the advantages claimed by the firm of Benary.

The individual Heterosis Tomato plant is a very strong grower and heavy bearer. Five trusses have been generally left, and each of these has carried from twenty-five to twenty-eight medium-sized but very regular fruits. However, its maturity is decidedly late, being about a fortnight later than the variety Best of All. Indoors, it has proved somewhat disappointing, for the fruits are too small to be of real market value, and too late; but this could, perhaps, be improved under better and more skilful cultivation. As for the yield, which has been generally very large this year, Tomato Heterosis surpasses the other best croppers by about ten to fifteen per cent. Some seeds have been saved for experimental purposes next year. *A. R. Lugeon, Ecole d'Agriculture, Morges, Switzerland.*

ASTER ERICOIDES.

Of the several Asters which are native hereabouts, A. ericoides is one of the most distinct. It occurs plentifully, both in open situations and in semi-shade, always preferring rather dry soil. In suitable situations it forms shapely, bushy specimens up to three feet in height. The stems are slender and paniculately branched, with the small, white flowers arranged in racemose manner along the upper side of the stem-branches. The leaves are slender, those of the stems being narrowly linear and acute. Individual flower heads rarely exceed three-quarters-of-an-inch in diameter. Several varieties of A. ericoides have been described, including pilosus, platyphyllus, depauperatus, Randii and parviceps, for as with many other members of the genus, A. ericoides has a strong tendency to variation.

N. Taylor, who is responsible for the treatment accorded to the genus Aster in Bailey's *Standard Cyclopedia of Horticulture* does not appear to regard this species as of any particular merit as a garden plant, for of it he states: "Not very showy. Useful for naturalising in open, dry situations." Nicholson's *Dictionary of Gardening* describes Aster ericoides as "A very pretty species," so in the words of the showman, "You pay your money and take your choice."

I recall that at Kew A. ericoides was effectively used to form a front row to the border of Asters which was planted along the path between the T-range and the rock garden.

ASTER SKYLANDS QUEEN.

A new hardy Aster exhibited at the Greenwich (New York) fall flower show, by Mr. T. Winskill, of Skylands Farm, Sterlington, New York, received much favourable comment from professional gardeners, and it is certainly a worthy addition to the many fine varieties which have been raised during comparatively recent years. Although most of the parent species are natives of North America, we in the New World have, in the past, depended almost entirely upon European raisers for improved horticultural varieties of these fine hardy plants. As a matter of fact, the hardy Asters have been almost neglected here as garden plants until comparatively recent years, but their worth is now being recognised, and they are fast gaining popularity.

Aster Skylands Queen is of the Novi-belgii section, but is dwarfer than most of the Novi-belgii varieties, for it does not exceed a height of two feet, and is of a branched, bushy habit with rather large, glossy foliage. During mid-September it bears a profusion of exceptionally large flowers of a clear, light blue colour, practically equalling the best varieties of the Amellus type in this respect. It makes a very fine pot plant, and by propagating it by means of cuttings during June, very dwarf, branched, floriferous examples are obtained in four- or five-inch pots by the flowering season, when they should prove of great value for conservatory or house decoration.

Mr. Winskill—an Englishman by birth—has made a hobby of growing and raising hardy Asters for a number of years, and he is enthusiastic over his latest creation, which he has named Skylands Queen. He told me that the new variety is a seedling, having the variety British Queen as the seed parent. *T. H. Everett, New York, U.S.A.*

SOCIETIES.

ROYAL HORTICULTURAL.

November 5:—Following the series of Special Shows, the Royal Horticultural Society has reverted to the normal miscellaneous one-day show, and with November paintings of flowers and garden scenes and sundries are admitted. It was a very small show in the new Horticultural Hall, Westminster, on the above date, although the attendance was larger than is usual late in the autumn. Orchids were shown in considerable quantity and beauty. The Orchid Committee recommended four First Class Certificates to novelties. The principal subjects before the Floral Committee were some excellent Nerines, hardy trees and shrubs displaying good autumn colouring, Carnations and late Roses. The Floral Committee recommended one Award of Merit to a berried shrub. Although there was no exhibit before the Fruit and Vegetable Committee, that body performed valuable work in naming many samples of Apples and passing judgment on various seedlings.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Fred J. Hanbury, Mr. J. Wilson Potter, Mr. Lionel de Rothschild, Mr. Richard G. Thwaites, Mr. Robert Paterson, Mr. T. Armstrong, Mr. Charles H. Curtis, Mr. J. E. Shill, Mr. J. Cowan, Mr. Fred K. Sander, Mr. A. Dye, and Mr. A. McBean.

First Class Certificates.

Vuylstekeara Etna, Stamperland var. (Miltonioda Harwoodii × Odontioda Charlesworthii).—A gloriously beautiful Orchid combining four genera in its composition. The plant shown was vigorous and had a branching spike carrying twenty-two flowers and buds. The open flowers are light, velvety crimson, a lovely glowing shade, but the wide, large and slightly frilled lip is deep cerise rather than crimson, with a small golden disk. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Laelio-Cattleya Queen Mary, Stonehurst var. (L.-C. Lustre × C. Peetersii.).—A magnificent variety of this popular hybrid. It has very ample, mauve-purple sepals and petals and a huge, well-expanded, frilled lip of deep purple hue, flushed with ruby. Shown by Robert Paterson, Esq.

Brasso-Laelio-Cattelya Queen Elizabeth (B.-C. British Queen × L.-C. Ivanhoe).—This splendid hybrid has soft rosy-mauve sepals and petals, the former having a few pale streaks towards the base. The wide, rounded, frilled lip is of a deeper mauve shade, with a wide, soft, orange-yellow area in front of the short, white, purple-veined throat. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Brasso-Laelio-Cattleya Heliolata, Dell Park var. (Cattleya Heliodor × Brasso-Laelio-Cattleya maculata.).—Yet another wondrously attractive and beautiful Orchid to add to the fine series of yellow-flowered hybrids raised at Dell Park. The flower is of very fine form and good size, and wholly of a soft amber-yellow colour save for a faint orange tint over the centre of the rounded, frilled lip. Shown by Baron Bruno Schröder.

Groups.

Although the number of exhibits at this meeting was limited, there were several excellent groups of Orchids.

Messrs. Sanders, Ltd., set up an interesting collection, showing Cattleya labiata var. in grand condition, together with several good plants of Oncidium tigrinum and O. bicallosum. Other notable Oncidiums were O. crispum var. grandiflorum, O. Forbesii, O. praetextum and O. varicosum var. extraria. Cattleya ardentissima, C. Fabia var., C. Fabianid, C. labiata var. Pescatorei, C. Bridal Veil, C. Portia and C. Gertrude Hollington, were shown well, together with Laelio-Cattleya Sunburst, L.-C. Walter Gott, L.-C. Gothaurea, L.-C. Erica Sander and L.-C. Fame; various Cypripediums, Bulbophyllum cupreum, Rodriguezia secunda, Sarcanthus acutifolium, and several other uncommon subjects.

Messrs. Cowan and Co. had fine specimen plants of several grand Orchids, including Cattleya Snowdon, C. labiata var. autumnalis, C. Fabia, C. Daedalus and C. Gloriette; Cypripedium Rosettii, C. Griffin, C. Ranleigh, C. Goliath and C. Actaeus; Odontioda Antirious, very fine, Brasso-Cattleya Nestor and Laelio-Cattleya Hilary.

Odontoglossums and Odontiodas were prominent in the small group set up by Messrs. Charlesworth and Co., Ltd.; among the former we noted O. grande, O. Toreador, O. Omega and O. Reve d'Or, while good Odontiodas were O. Pandora, O. Colinge, O. Geisha, O. Alesia and O. Clusia. This firm also showed the quaint Epidendrum xanthinum and E. ciliare, Cattleya Hardyana var. alba and C. Weedon-aurea, together with several fascinating Brasso-Laelio-Cattleyas, and Pleione Wallichiana in good condition.

Messrs. J. and A. McBean had well-flowered specimens of Cattleya labiata, C. A. M. Nicholas, C. Louise, C. Prince John and C. aureata; Miltonia vexillaria var. Leopoldii; Laelio-Cattleya Inez, Brasso-Cattleya Alexandrina and Brasso-Laelio-Cattleya Rowena, with several choice Cypripediums.

Several excellent plants of Vanda coerulea with flowers, in some instances, almost pure white, were shown by Mr. J. Evans, together with Oncidium bicallosum and O. tigrinum var. Rogersii.

Messrs. Stuart Low and Co. staged an interesting group which included grand plants of Laelio-Cattleya Cantab, L.-C. Gottiana, L.-C. Crowborough, L.-C. Radina and L.-C. Pioneer; Cattleya Fabia, C. General Jacques, C. Lancing, C. Gatton Ruby, C. Miguelito and C. Fabia; and Brasso-Cattleya Penelope, B.-C. Heatherwood, B.-C. Mars and B.-C. Poilu. They also showed various Cypripediums, Oncidiums and the lovely Brasso-Laelio-Cattleya Gordon Highlander.

F. J. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead, showed two new Cypripediums—C. Florence E. King (C. Arethusa × C. Mercurius), and C. Ruby Gem (C. Niobe × C. Euryades).

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. G. W. Leak, Mr. Arthur Turner, Mrs. Ethel M. Wightman, Mr. Donald Allan, Mr. James B. Riding, Mr. A. E. Vasey, Mr. J. M. Bridgeford, Mr. William Howe, Mr. Charles E, Pearson, Mr. W. B. Gingell, Mr. D. Ingamells, Mr. B. R. Long, Mr. D. B. Crane, Mr. R. Findlay Mrs. Helen Lindsay Smith and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. G. Reuthe, Mr. W. G. Baker, Mr. A. Bedford, Mr. Amos Perry, Mr. W. Irving, Mr. W. B. Cranfield, Mr. E. H. Wilding, Mr. R. C. Notcutt, Mr. F. G. Preston, Mr. T. Musgrave, Mr. Mark Fenwick, Mr. Reginald Cory, Mr. E. A. Bowles, Sir William Lawrence, Bart., Miss E. Willmott (visitor), and Mr. N. K. Gould, Secretary.

Award of Merit.

Lonicera Hemsleyana.—A Chinese, deciduous species of slender, graceful habit. The smallish, ovate-lanceolate leaves have rather longer stalks than is usual in the genus. The attraction at this season lies in the little bunches of fruits which are of bright red colour with the semi-transparency seen in the edible Red Currant. Shown by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Hampshire.

Other Novelties.

In addition to the Honeysuckle which received award, Lionel de Rothschild, Esq., showed sprays of Lonicera pileata var. yunnanense, a neat habited evergreen, bearing small, shining, green leaves and shining purple fruits. The Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, sent fruiting sprays of Pyrus Malus var. toringoides, one of the most attractive of the small-fruited Crabs; Pyrus Sorbus and Crataegus Dippeliana. The Countess of Cawdor (gr. Mr. H. Windebank), Frensham Hall, Haslemere, showed, in Galanthus Olgae, a very early Snowdrop, and also sprays of highly-coloured Berberis Giraldii and berried sprays of Gaultheria procumbens. Mrs. Maurice Pope (gr. Mr. W. Hiscock), Athwick Hall, Marshfield, Chippenham, sent a beautiful flowering spray of Bignonia venusta, from the cool greenhouse. Carnation Startler, shown by Messrs. C. Engelmann, Ltd., is a large, well-formed greenhouse variety of vivid scarlet colour, and is slightly fragrant.

Groups.

A small collection of excellent Nerines in pots was shown by Mr. W. H. Walters. The very best of the exceptionally good varieties were Lady Louise Loder, Mrs. E. Cator, Miss Ruggles and Mrs. H. T. Elwes.

Large collections of fresh and bright Carnations were arranged by Messrs. C. Engelmann, Ltd., and Messrs. Stuart Low and Co. The former had, in Madge, Duchess of York, Citron, Nina, Nero and Chirtz, vases of good Fancies, and staged the self-coloured sorts equally well. In the other collection, the bright pink varieties were well represented by Kathleen, Master Michael Stoop and Thomas Ives, while the best of the crimson sorts were Topsy, Philip Sassoon and Ruby Glow. Mr. G. Zambra staged good vases of Sweet Violets and included the varieties Princess of Wales and Princess Mary.

Very good late autumn Roses were displayed by Mr. J. H. Pemberton, whose best varieties were W. F. Dreer, Los Angeles, Bernice, Anne and Madame Butterfly. Messrs. Wheatcroft Bros. had several vases of the bright little variety Peter Pan.

An attractive collection of market type Chrysanthemums was staged by Mr. A. G. Vinten. The Singles were particularly good, and these included Phyllis Cooper, J. H. Blyth, Jessica and October Pink. Chief among the Japanese varieties were Yellow Marvel, Shirley Scarlet and sprays of Fifi.

Especially well coloured branches of trees and shrubs were set up by Messrs. Baggesens. Along the centre of the group they had many branches of an Oak, while the most vivid colour was provided by a vase of Cerasus Hisakura. Berberis Thunbergii was also richly coloured, while sprays of Enkianthus campanulatus of yellow and scarlet colouring were very beautiful. Messrs. L. R. Russell, Ltd., staged small Conifers, Ivies, Pernettya mucronata, Nandina domestica and several hardy Fuchsias. The Countess of Cawdor filled a table space with various Hollies bearing large quantities of brightly coloured berries.

The Sewell Medals which are periodically offered for exhibits of six alpines in pots or pans seem to be much more popular with amateurs than with the trade. In this autumn competition there were four exhibits from amateurs, but none from traders. The amateur's Medal was awarded to G. P. Baker, Esq., Hillside, Sevenoaks, for well-grown pans of Sedum creticum, Ramondia Heldriechii, R. pyrenaica, Saxifraga longifolia, Ebenus cretica and Saxifraga scardica. Mark Fenwick, Esq. (gr. Mr. W. Fustin), Abbottswood, Stow-in-the-Wold, Gloucestershire, had, in pans of Cyclamen neapolitanum, Ononis Natrix and Parochetus communis, three good late-flowering alpines. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, staged well-grown pans of Gaultheria procumbens, Sedum spathulifolium var. purpureum and Cotyledon chrysantha. Mrs. Torkington, The New Hall, Maidenhead, included Verbena chamaedryoides, Linaria verticillata, Cheiranthus Senoneri and Gentiana sino-ornata in flower.

Exhibits of paintings and garden designs were permitted at this meeting, and several interesting collections were shown, although the screens upon which the paintings were hung were not generally admired.

Mr. Percy S. Cane exhibited several large photographs of various gardens, while paintings of plants, garden scenes, etc., were shown by Miss M. Linnel, Miss Edith A. Anderson, Miss Ellen Warrington, Miss Winifred Walker, who had numerous flower studies, including many Narcissi; Miss M. Skinner, Miss E. Frances Drake, Miss A. Strickland, Miss Ellenor S. Ough, Miss Eva Kirkpatrick, the Hon. Mrs. R. Boyle, Miss A. T. Wilkinson, Mrs. M. Townsend, Mrs. H. Spencer and Miss G. E. Bayley.

Miss Winifred M. A. Brooke had an interesting series of illustrations of garden pests, and there was also an exhibit of paintings of fruits executed for the Society by W. Hooker in 1815-16.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. W. Poupart, Mr. A. Poupart, Mr. C. G. A. Nix, Mr. E. Beckett, Mr. G. F. Tinley, Mr. P. A. Tucker, Mr. E. A. Laxton, Mr. J. Cheal and Mr. A. N. Rawes, Secretary.

A number of seedling Apples was shown before this Committee, but none received recommendation.

The Committee also had numerous Apples and Pears before it for naming, but there were no exhibits of fruits in the hall.

The following awards have been made to the undermentioned flowers and vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Kniphofias.

Awards of Merit.

(75) *Wisley Seedling*, entered by the R.H.S. Gardens; (83) *Fireflame*, sent by Messrs. Ruys; and (70) *Excellence*, sent by Messrs. Maurice Prichard and Sons.

Highly Commended.

(4) Lemon Queen, sent by Mr. R. C. Notcutt, Woodbridge.

Gladioli.

Awards of Merit.

(4) *Harmony*, (5) *Mrs. Unwin*, (7) *Emma*, (10) *Gladness*, (12) *Adoration*, and (13) *Captain Boynton*, all sent by Messrs. Velthuys, Hillegom.

Highly Commended.

(2) Ne Plus Ultra, (6) La Gaiété, and (8) The Queen, also sent by Messrs. Velthuys.

Fuchsias (Greenhouse).

Awards of Merit.

(10, 11) *Ballet Girl*, sent by Messrs. John Forbes, Ltd., and (50) *Cupid*, sent by Mr. W. Auton, alike; (12, 13), *Dainty Lady*, by Messrs. Dobbie and Co., Ltd., and Messrs. Carter Page, Ltd., and (73) *La France*, by Messrs. Dobbie and Co., Ltd., alike; (119) *Charming*, by Messrs. Dobbie and Co., Ltd., (137) *No. 3*, by Mr. Cory, Cardiff, and (14) *Display* (wrongly named), by Messrs. H. J. Jones, alike; (36) *Mrs. Marshall*, entered by the R.H.S. Gardens, (37), *Grande Duchess Marie*, and (83) *Leonardo di Vinci*, by Messrs. H. J. Jones, alike; (59) *Andenken A. H. Henkel*, by Messrs. Dobbie and Co., Ltd.; (60, 61), *Coralle*, by Messrs. H. J. Jones and Mr. Cory, Cardiff; (71) *Emile Zola*, by Messrs. John Forbes, Ltd.; (91) *Masterpiece*, by Messrs. John Forbes, Ltd., and (92) *Le Robuste*, by Messrs. H. J. Jones, alike; (79, 80) *Mauve Beauty*, by the Castle Nurseries and by Messrs. Dobbie and Co., Ltd.; and (126, 127) *Sunrad*, sent by Messrs. Carter Page, Ltd., and Messrs. John Forbes, Ltd.

Highly Commended.

(15) Display, sent by Messrs. Carter Page, Ltd.; (22) White Phenomenal, by Messrs. John Forbes, Ltd.; (23) Late Perfection, entered by the R.H.S. Gardens, and (68), Gartenmeister Bonstedt, by Messrs. John Forbes, Ltd., alike; (26) Earl of Beaconsfield, by Messrs. Dobbie and Co., Ltd.; (34, 35, 200) Fascination, by Mr. G. Carpenter, the Castle Nurseries, and Messrs. Philip Ladds, Ltd. and (49) Rose Ballet Girl, by Messrs. Carter Page, Ltd., alike; (39) Balkon, (46) Princess Mary, (54) Marinka, and (67) Aurora Superba, all sent by Messrs. H. J. Jones; (74) Rose of Castille, entered by the R.H.S. Gardens; (75, 76) Rose of Castille Improved, sent by Messrs. John Forbes, Ltd., and Messrs. Carter Page, Ltd.; (87) Scarcity (wrong name), by Messrs. John Forbes, Ltd.; (93) Killiecrankie (wrong name), by Messrs. John Forbes, Ltd., and (141) Carmen, by Sir Wm. Lawrence, all alike; (85) Beauty, by Messrs. John Forbes, Ltd.; (100, 101) Golden Treasure, by Messrs. John Forbes, Ltd., and Messrs. Dobbie and Co., Ltd.; (118) Clipper, by Messrs. John Forbes, Ltd.; (136) No. 2, by Mr. Cory; and (198) Unnamed, sent by Messrs. Bakers.

Fuchsias (Hardy).

Award of Merit.

(168) *Thompsonii*, sent by Messrs. R. Veitch and Son.

Highly Commended.

(156, 158), gracilis, sent by Messrs. J. Cheal and Sons, Ltd., and by Messrs. John Forbes, Ltd.; and (192) Americana, sent by Sir William Lawrence, Dorking.

Herbaceous Veronicas.

Award of Merit.

(69) *Exaltata*, sent by Messrs. John Forbes, Ltd.

Heleniums.

Award of Merit.

Wyndley, sent by Messrs. Carter Page, Ltd.

Larkspurs.

Awards of Merit.

(3) *Exquisite Rose*, and (4) *Exquisite Pink Improved*, sent by the Waller-Franklin Seed Company, California; and (5) *La France*, sent by Messrs. Bodger, California.

Perennial Gaillardia.

Highly Commended.

(9, 19) Tangerine, sent by Messrs. Barr and Sons, and by Messrs. Daniels Bros.

Godetia.

Highly Commended.

(6) Tall Double Cherry Red, sent by Messrs. Sutton and Sons.

Dwarf French Beans (Wax-Pods).

Award of Merit.

(16) *Perfection Butter*, sent by Messrs. Barr and Sons.

Highly Commended.

(2) Schlossperle, sent by Messrs. Heinemann, Erfurt, and (12) Kidney Wax, sent by Messrs. Burpee, California.

(Edible Green-Podded).

Commended.

(21, 22) Saxa Stringless, sent by Messrs. Zwaan and Van der Molen, and by Messrs. Heinemann.

(Tough Green-Podded).

First Class Certificate.

(66) *The Wonder*, sent by Messrs. Watkins and Simpson.

Awards of Merit.

(68) *The Wonder*, like the preceding, and (69) *Satisfaction*, sent by Messrs. Dobbie and Co., Ltd.; and (90) *Unrivalled*, sent by Messrs. Clucas.

Highly Commended.

(102) Fifty Days, sent by Messrs. James Carter and Co.; (29) African Wonder, by Messrs. Cooper Taber; (33) Ne Plus Ultra Selected, by Messrs. Hurst; (53) Bounteous, by Messrs. Watkins and Simpson; (60) Superlative, by Messrs. Nutting, and (62, 63) Magpie, by Messrs. James Carter and Co., and Messrs. Harrison, alike; (82) Canadian Wonder, by Messrs. Harrison; and (87) Canadian Express, and (88) Lightning, sent by Messrs. James Carter and Co.

Commended.

(35) Harbinger, and (74) Supreme, sent by Messrs. E. Webb and Sons, Ltd.; and (52) Holborn Wonder Stringless, sent by Messrs. James Carter and Co.

Broad Beans.

Awards of Merit.

(45) *Exhibition Giant*, sent by Messrs. E. W. King and Co.; (51) *Champion Longpod*, by Messrs. Dobbie and Co., Ltd.; (73) *Olympic Green-longpod*, by Messrs. Hurst and Son; and (79) *Green Leviathan*, sent by Messrs. James Carter and Co.

Highly Commended.

(20) Unrivalled Green Windsor, sent by Messrs. Sutton and Sons; (26) Four Seeded Windsor, re-selected, by Messrs. Hurst and Son; (34) Seville Longpod, by Messrs. Watkins and Simpson; (36) Longpod Selected, by Messrs. E. Webb and Sons, Ltd.; (37) Mammoth Longpod, by Messrs. Pennell; (40) Prolific, by Messrs. Dickson and Robinson; (44) Exhibition Longpod, by Messrs. Clucas; (54) Exhibition (Bunyard's), by Messrs. W. H. Simpson, and (57) Exhibition Longpod, by Messrs. Pennell (alike); (59) Hangdown, by Messrs. Sluis en Groot; (64) Sussex Wonder Longpod, by Messrs. Watkins and Simpson; (66) Kinver Mammoth, by Messrs. E. Webb and Sons, Ltd.; and (76) Mammoth New Green Longpod, sent by Messrs. Barr and Sons.

Commended.

(12 and 21) Mammoth Windsor, and (23) Homestead Green Windsor, sent by Messrs. James Carter and Co.; (27) Four Seeded Green Windsor, sent by Messrs. Middlehursts.

WIMBLEDON GARDENERS'.

The fortnightly meeting of the Wimbledon Gardeners' Society took place at the Queen's Hall, Wimbledon, on October 23. Mr. A. Hosking, of John Innes Horticultural Institution, presided, and there was again a good attendance.

Mr. J. Coutts, Assistant Curator, Royal Gardens, Kew, gave a splendid lecture on Roses. Seventy slides—many of which were coloured—were shown on the screen, and helped the audience to thoroughly grasp all the points which Mr. Coutts noted. The lecture was a lengthy one, but great attention was sustained throughout. An interesting discussion followed, and many questions were asked, after which Mr. F. Low, Vice-Chairman, proposed a vote of thanks to Mr. Coutts for his kindness in coming to Wimbledon and giving such an excellent lecture; this was seconded by Mr. K. Norrie, and passed unanimously.

Two specimens of interest were shown at this meeting, a branch of Scarlet Oak, by Miss Wiffen, and a Rose branch, very much fasciated, by Mr. E. Abrahams. These were commented upon by the Chairman, who then announced that owing to the Annual Exhibition occurring on November 13, there would not be a meeting until November 27, when Mr. G. B. Begg, of the John Innes Horticultural Institution, would lecture on "The Ideal Commercial Orchard."

AYRSHIRE AGRICULTURAL.

At the Annual Show of this Association, held at Kilmarnock on October 24 and 25, the Championship Medal for Potatos was awarded to a dish of Arran Banner, grown by Mr. William Laidlaw, Sanquhar, Dumfriesshire, who also secured the reserve honour and the first prizes in the classes for eighteen varieties, six varieties, and six tubers any white, round variety. Mr. James Thomson, Sanquhar, excelled with twelve varieties and nine varieties.

In the competition for fruits, Mr. A. Harvey, Rozelle Gardens, Ayr, provided the best collection of culinary Apples, six Pears, twelve Pears and the five heaviest Pears, while Mr. James Thomson was successful in the classes for a collection of dessert Apples, nine culinary Apples, nine dessert Apples, and the five heaviest Apples.

Other awards were:—Twelve red Tomatos, Mr. Archibald Brownlee, Largs; nine Onions, Mr. A. Harvey; and a collection of vegetables, Mr. Alex. Baillie, Kilmarnock.

HASTINGS (HAWKE'S BAY) HORTICULTURAL.

An exceptionally fine display of Daffodils was a feature of this Society's Spring Show, held in the Assembly Rooms, Hastings, New Zealand, on September 21. A large attendance, despite counter attractions, was ample evidence of the live interest taken by amateurs in floriculture; in fact, on travelling through the Dominion one is forcibly impressed by the general appearance and variety of "home" flowers to be found in the gardens of bungalows around the towns.

The principal exhibit was from Mr. J. G. Weightman, of Fielding, among whose blooms were some beautiful and perfect specimens of Hallmark and Honey Boy—yellow Trumpets; Beersheba and Kantara—white Trumpets; Gretchen, Militant Puzzle and Scarlet Pimpernel—Incomparabilis; with Madonna and Tenedos among the Leedsii group; and Lady Superior and Lady Moore among the Barrii forms. Cambridge was the champion bloom.

The entries by amateurs were good and numerous, including many in the classes for flowering shrubs, Freezias, Hyacinths, Polyanthuses and Cinerarias, in addition to many attractive floral baskets.

Perhaps the most popular exhibits were those of decorated dinner tables and mantlepieces, many of which displayed great taste and discrimination on the part of the exhibitors. The Society, which is affiliated to the R.H.S. (England), has every reason to be satisfied with its effort, which is bound to have a stimulating effect upon horticultural development in the Hawke's Bay district.

Particular interest was taken in the Daffodils at this year's show, since Mr. Guy L. Wilson, the noted Irish raiser, is at present visiting the Dominion, judging the exhibits at the Lower Hutt and Wellington Shows this week (September 21).

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on October 4, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, J. Evans, A. Keeling, W. J. Morgan and H. Arthur (Secretary).

First Class Certificate.

Cattleya Valencia, Towneley Grove var.—From J. B. Adamson, Esq.

Cultural Certificates.

To Mr. A. Burns, for Catasetum Bungerothii; and to Mr. W. J. Morgan, for Cypripedium Charlesworthii var. Bromilowiae.

Groups.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, staged a group to which a Large Silver Medal was awarded; it included Cattleyas armainvillierense, C. Soulange and C. Adula, Bridge Hall variety; Odontoglossum grande, Epidendrum vitellinum, Phalaenopsis Esmeralda, Habenaria rhodocheila, Cycnoches ventricosum, and others. J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged Cypripedium Eury. Belge in addition to the Cattleya certificated.

Messrs. A. J. Keeling and Sons, Bradford showed Cypripedium Black Prince and C. Rosettii var. Goliath, with Cattleya Golden Rain, and Mr. John Evans, Colwyn Bay, staged Cypripedium Felicity and C. Selene, with a Miltonia seedling.

At the meeting held on October 18, the members of Committee present were Messrs. Hy. Astley-Bell (in the chair), J. B. Adamson, A. Burns, A. Coningsby, J. Evans, A. Keeling, and H. Arthur (Secretary). Mr. A. E. Dale was invited to sit with the Committee.

Awards of Merit.

Cypripedium Griselda (*C. Dreadnought* × *C. Amandinae*) and *C. King Arthur var. Tamworth.* From Messrs. A. J. Keeling and Sons.

Cypripedium Mrs. A. E. Dale (*C. Christopher var. Grand Duke Nicholas* × *C. Shogun*).—From A. E. Dale, Esq.

Cattleya Mrs. Medo var. Regina.—From Mr. John Evans.

Cultural Certificate.

To Mr. A. Coningsby, for Cattleya Mantinii var. splendens.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged Cypripedium M. Ogilvie var. Imperator, C. Eurybiades var. The King, C. Sunrise, C. Dante, C. Tom Abbott, C. Gaston Bultel and C. King Edward VII, with Miltonia Binotii.

Captain W. Horridge (gr. Mr. A. Coningsby), Bury, staged two fine plants of Cattleya Mantinii var. splendens, and Messrs. A. J. Keeling and Sons showed, in addition to the plants gaining awards, Pachystoma Thompsoniana, Barkeria spectabilis, and Odontioda Leonidas. Mr. John Evans, Colwyn Bay, staged Odontoglossum Omega and a blotched hybrid.

GUILDFORD GARDENERS'.

For the opening lecture of the ensuing season, this Society was favoured with a visit by Mr. H. H. Cook, of Reading, who delivered a very interesting lecture on "The Forcing of Vegetables and Salads." Mr. Cook spoke from a practical knowledge gained in Ireland and elsewhere, and he detailed the best methods for securing successful results. The Mushroom-house is his ideal forcing house.

Mr. Turner, of Albury Park, in proposing a vote of thanks, said it was a happy thought to begin the lectures with this topic. It came just at the right time for gardeners to make their plans, and carry out the valuable hints Mr. Cook had given. Mr. Newan, of Tangley Place, seconded the vote, and referred to the interest Mr. Cook had taken in the Guildford Association, this being his third visit. These expressions were supported by the President, Mr. W. T. Patrick, who presided.

On a proposition made by the Editor of the monthly *Journal* of this Society, Mr. Cook was asked to convey the friendly greetings of the members to the Reading Gardeners' Society, which he undertook to do.

The next meeting is fixed for November 12, when Mr. A. E. Burgess, of the Surrey County Council, will deal with "Manures and Manuring." The annual meeting of the Society will be held on November 19.

SPALDING POTATO SHOW.

A large entry and the high quality of the exhibits characterised the Holland (Lincolnshire) County Potato Show, held at Spalding on October 24. A favourable season has resulted in all-round excellence, and the exhibition proved a notable one in a district already famed for its Potatos.

Entries numbered 330, about the same as for the past two years. Ware Potatos were the strongest section, and the judges declared that better quality ware Potatos had not previously been seen at this show.

An outstanding feature was the classes for single dishes of King Edward and Majestic. The exhibits of the small-holders were highly commended, and were nearly up to the standard of the large growers.

The winners of special prizes, Challenge Cups, and Gold and Silver Medals, comprised the following :—Mr. C. Ibbott, of Holbeach, near Spalding ; Mr. J. Fox, Weston Hills, Spalding ; Messrs. D'Alcorn and Son, of Spalding ; Mr. Cecil Robinson, of Quadring, near Donington ; Mr. S. Markillie, of Longsutton ; Mr. H. Roughton, of Holbeach ; Mr. T. A. Pick, of Deeping Saint Nicholas, near Spalding ; Mr. W. H. Fuller, of Lincoln ; Mr. A. B. Bass, of Holbeach Marsh ; Mr. William Gilding, Chairman of the Show Committee, of Swineshead, near Boston ; Mr. E. S. Markillie, of Longsutton ; Mr. G. W. Naylor, of Moulton Marsh, Spalding ; Mr. J. Cox, of Weston Hills ; Messrs. Gratton and Sons, of Boston ; Messrs. Harrison McGreggor and Co., of Leith, Lancashire ; and the Allied Guano Chemical Company, London.

IPSWICH GARDENERS'.

About sixty-five members were present at the montly meeting of the above Association in mid-October. The meeting was presided over by W. Bradbury, Esq., and the lecturer for the evening was Captain F. S. Harvey Cant, the eminent Rosarian of Colchester, who delivered and extremely interesting lecture on Roses.

He reviewed the numerous varieties which have been introduced to cultivation during the last dozen or so years, and gave many valuable cultural hints.

An interesting feature of this meeting was the large array of exhibits for the monthly competition.

BRITISH GLADIOLUS.

The Annual Meeting of the British Gladiolus Society was held at the new R.H.S. Hall, on the afternoon of October 23. The President, Major George Churcher, occupied the chair, supported by a good gathering of the Society's members.

The report disclosed a happy state of affairs, and indicated that this young Society had experienced a record year in all directions, the most surprising feature being the increase in membership of 221 and six new affiliated societies—making the total membership at the end of September 535, including eighteen affiliated societies. A letter of thanks and appreciation from the Chairman of the Southport Flower Show Committee was read, and an intimation that the Society would be invited to hold its 1932 " International " at Southport was received with acclamation.

Major G. Churcher was re-elected President, and the names of Colonel F. E. Durham, C.B.E., E. S. Cahill, Esq. (Australia), and A. C. Collingridge, Esq., were added to the list of Vice-Presidents. Mrs. J. C. Collingridge, a splendid worker for the Society and its only lady Vice-President, was unanimously elected a Patron. The Hon. Secretary, Mr. A. E. Amos ; Hon. Librarian, Captain A. H. Amor ; and the Society's Auditors, Messrs. Cooper and Norfolk, Colchester, were re-elected with thanks for past services. The following additional members were elected to the Council for 1930 :—Messrs. J. J. Keen, Southampton ; L. C. Adkins, Chelmsford ; and G. C. Taylor, London.

In 1930, the Society will again hold two exhibitions, one at Taunton (in conjunction with the Taunton Deane Floricultural Exhibition) on August 13 and 14, and a small exhibition at the new R.H.S. Hall, London, on August 26. Messrs. R. H. Jeffers (London), F. W. Hellings (Kingston), and T. J. Child (Catford), were unanimously elected Show Superintendents.

A motion that the Society's Silver-gilt Medal be presented to Mr. T. E. Wolstenholme, Secretary of the Southport Flower Show, as a memento of the 1929 " International," and a token of appreciation, was carried with much applause.

ANSWERS TO CORRESPONDENTS.

Carnations Infested with Red Spider.—*S. G.* A spray which has been successful in controlling red spider on Carnations is the Cheshunt formula for liver of sulphur oil wash. To prepare this :—(1) Dissolve 1 oz. of commercial liver of sulphur in 4½ fluid ozs. of soft water ; (2) heat in a large saucepan 2 oz. potash soft soap with 1 fluid oz. of fusel oil, and stir until all the soap has completely dissolved. When No. 2 is cold, strain No. 1 through a fine cloth into it. Shake the mixture before diluting it with soft water at the rate of one part to forty-nine parts of water. This wash will not remove the " bloom " from Carnation foiiage.

Names of Fruits.—*J. K.* 1, Watcombe Hero ; 2, Northern Greening ; 3, Emperor Alexander ; 4, Court Pendu Platt ; 5, Yorkshire Greening ; 6, badly damaged, cannot identify ; 7, Lane's Prince Albert ; 8, James Grieve (poor specimen) ; 9, Reinette du Canada.—*J. J. H.* 1 and 4, Newton Wonder ; 2, Northern Greening ; 3, Beauty of Stoke.—*J. P.* 1, Blenheim Pippin ; 2, Lord Derby ; 3, Barnack Beauty ; 4, Wealthy; 5, possibly Winter Greening ; 6, Allington Pippin ; 7, Hubbard's Pearmain.—*Kentish Cob.* 1, Golden Noble ; 2, Gravenstein.—*R. W. T.* Possibly Mrs. Phillimore, but difficult to be certain as the fruit was a poor specimen.—*F. W. D.* 1, Charles Ross ; 2, Endsleigh Beauty ; 3, Worcester Pearmain ; 4, Minchell Crab ; 5 and 6, Christmas or Claygate Pearmain—these specimens were too poor to make certain of this.—*I. R.* 1, Gold Medal ; 2, Northern Greening ; 3, Ribston Pippin.—*G. S.* 1, Golden Spire ; 2, possibly Northern Greening ; 3, Fertility ; 4, Brown Beurré.—*D. C.* Mrs. Phillimore.

Names of Plants.—*Budleigh.* Hippophae salicifolia (the Himalayan Sea Buckthorn).—*G.* Polygonum amplexicaule. *G.* Shrub, Double Myrtle ; Crocus, probably C. speciosus ; Moraea sp., send more material.—*G. S.* Danaea racemos, the Alexandrian Laurel.

Nephrolepis.—*R. W. R.* The " mossy " varieties of Nephrolepis exaltata require the shelter of a warm greenhouse or intermediate house. Although they delight in plenty of atmospheric moisture when making their new fronds, much less atmospheric moisture is desirable when the fronds are dense and from half to fully-grown. The frequent subdivision of the pinnae of these varieties gives the Ferns an added elegance, but such fronds hold the moisture, which causes breaking and damping.

Planting Plan for Border.—*W. W. W.* When considering a new planting scheme for your border, you might do worse than try a foliage effect, using such subjects as Centaurea candidissima, C. gymnocarpa, Coleus Vershaffeltii, Eucalyptus globulus, Iresines, Abutilon Thompsonii, Albizzia lophantha, Leucophyton Brownii, Veronica Andersoni var. variegata, and Artemisia arborescens, to mention a few. There are also several hardy grasses, such as Holcus mollis var. variegata, also the variegated forms of Dactylis glomerata, in short, use any plants with coloured or variegated foliage that you can conveniently secure. They should be arranged in groups of three, four or six plants ; the edging or front could be made up with groups of flowering plants, such as Lobelia and Alyssum. You can, of course, have a continuous edging of one subject, but a broken one is generally more effective ; this, however, is a matter of individual taste. There is no reason why groups of flowering plants should not be mixed with the foliage. A planting on these lines is bright at all times, and remains effective until the end of the season. If you must have flowering plants, you could try a scheme in blue, using groups of Salvia farinacea at the back, along with Eucalyptus globulus or some other grey-foliaged plant ; then a line of Salvia patens, followed with Delphinium Blue Butterfly, and an edging of blue and white Lobelia and white Alyssum. A few groups of a pale yellow plant, such as Calceolaria amplexicaulis, adds greatly to the effect. For a pink scheme, you could use, for the back, pink-flowered Pentstemons, followed with pink Verbenas in various shades, then Begonia semperflorens in pink shades, and an edging of white Lobelia or Alyssum. If you want a brighter effect, you could plant Dahlia Lemur at the back, then Salvia Glory of Zurich or Harbinger, followed by a scarlet Verbena, such as Defiance—easily raised from seeds—with an edging of a red B. semperflorens, interspersed with white Alyssum. We have tried, so far as possible, to suggest plants that can be raised easily from seeds. It is difficult to give planting schemes, unless we have some idea of your individual taste in colours, etc.

Primula japonica and Eelworm.—*A. P. D.* The plant of Primula japonica is heavily infested with the stem eelworm, Tylenchus dipsaci. It is due to the presence of this worm that there is proliferation of buds in the centre of the plant. This pest is exceedingly difficult to control. Diseased plants and decayed parts of the plants still remaining in the soil should be removed and burnt and not placed on the rubbish heap. Primula japonica should not be planted in the infected area for a period of at least three years, but should be replaced by Irises or other waterside plants.

Rating Relief.—*J. W.* If your holding consists of land exceeding one-quarter-of-an-acre used for the purpose of poultry farming, orchard or cottage garden, and comprises a dwelling-house, and you are primarily engaged in carrying on or directing agricultural operations on the agricultural land connected with the house, you are entitled to have the house assessed at a lower valuation than if it was assessed as a dwelling-house for general use. The Act provides for an appeal to Quarter Sessions if anyone is not satisfied with the decision of the Assessment Committee. The date fixed for applications to the Assessment Committee is any time before November 1 next.

Young Vines.—*F. G. R.* It is not good practice to plant young vines in an old border, but if you have removed the inside border with good compost, and examined the drainage, there is no reason why young vines should not continue to make satisfactory progress. In your case the spring of the year would be the best time for planting, when you start the Muscats. As the vines are healthy, see that they are thoroughly moist at the roots before being turned out of the pots ; have the drainage removed and the soil all round the roots loosened with a pointed stick ; spread out the roots carefully, two or three inches deep and set the collar about one inch deeper than it was in the pot. Make the soil firm, and give sufficient tepid water to settle the soil about the roots. Damp them slightly overhead three times a day with tepid water until new roots have pushed through into the new soil, and afterwards use every means, by careful watering, damping and airing, to encourage the vines to make free growth throughout the growing season.

MARKETS.

COVENT GARDEN, Tuesday, November 5, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—The general conditions throughout this department were somewhat disappointing last week. Chrysanthemums are far too numerous for trade requirements. The latest arrivals in disbudded blooms are Mrs Roots, Ada Brooker, Ivy Gay and Romance, and Lizzie Adcock, Scource d'Or and Jean Patterson are the most prominent in spray varieties. Single varieties, disbudded, in shades of red, pink, yellow and bronze, are the finest offered this season, and prices range from 2s. to 6s. per dozen blooms. Carnations remain steady in price, while supplies of best grade Roses are lessening and prices firmer. Lilium longiflorum remains at 4s. 6d. to 5s. per dozen, and supplies of Arums (Richardias) are still below requirements, with prices firmer for home-grown blooms. Orchids, both Cattleyas and Cypripediums, are much more plentiful. A few bunches of coloured Bouvardias have been on sale during the past week, while supplies of Gardenias, Lapagerias and Stephanotis are much shorter. Supplies from France are increasing almost daily. The first arrivals of Paper White Narcissi reached the market on Thursday last and were soon sold at very high prices. Yellow Marguerites and Carnations are arriving in a better condition, and more Parma Violets are expected for this week. Chillies and Solanum berries are now arriving in good condition, also several pads of Ruscus, Eucalyptus, Myrtle and Berberis.

Remarks.—There has been some slight improvement in the fruit section, although this has not been accompanied by a general increase in prices. The hothouse Grape department reports a better enquiry for best Grapes, but the competition of Belgian Grapes is unfavourable to the lower grades of English Grapes. English Apples are not entirely a satisfactory business, and the trade, even for top grades, has been variable; probably the increasing arrivals of Apples from abroad are the disturbing factor. Some fairly good English Pears have been available and met a moderate demand, although where other than the finest specimens are marketed in trays they have been difficult to sell at satisfactory prices. The Mushroom business is firm, best cups selling freely at good prices. Hothouse Beans from Guernsey and the Worthing district are doing rather better and should continue to do so now until the end of their season. The few good English Tomatos sell well, but indifferently-coloured produce is difficult to dispose of. Cucumbers are in shorter supply and an improvement in values is recorded. In the vegetable market Cauliflowers and Brussels Sprouts are a firm trade. Cabbages and Savoys are fairly plentiful and are selling at reasonable levels. The salads from France continue to meet a good demand, and the few English Lettuces available also sell well. Root vegetables are in moderate demand, and the colder weather is favourable to the Potato trade.

GLASGOW.

A good volume of business was transacted in the cut flower market last week and, while prices of certain varieties of Chrysanthemums displayed a slightly easier tendency, the general tone was steadier than it has been of late. Pink Consul were worth 1s. 6d. to 1s. 9d. for 6's; Pink Profusion, Cranford Yellow, Bronze Consul and La Pactole, 1s. to 1s. 6d.; White and Yellow Thorpe, 1s. to 1s. 2d.; Rose Maid, 1s. to 1s. 3d.; Sanctity, 8d. to 1s. 3d.; Almirante, 8d. to 1s.; Dolores, 7d. to 10d.; Jean Pattison, 2s. per bunch of 12's; Phyllis Cooper, 3s.; Mason's Bronze, 2s. 6d.; and Exmouth Pink and Pink Chieftain, 2s. 3d. Arums (Richardias) ranged from 6s. to 8s. per bunch; Violets, 4s. to 5s. per dozen bunches; Lily-of-the-Valley 2s. to 2s. 6d. per bunch; Carnations, 2s. to 3s. 6d. per dozen; pink Roses, 2s. 6d. to 4s.; red, 1s. to 2s.; Dahlias, 3d. to 4d. per bunch; Smilax, small, 1s., medium, 1s. 6d., and large, 2s.

Pot plants were in good demand, and made the following prices:—Heaths, 48's, 3s. 6d.; 60's, 1s. 6d.; Marguerites, 2s.; Solanum, 1s.; and Chrysanthemums, 2s. 3d.

Apples dominated the fruit market, and while prices continued comparatively high, they reflected a reduction of 1s. per case on larger imports from Canada and the United States. Delicious realised 18s. to 20s.; Jonathan, extra fancy, 16s. 9d.; fancy; 15s. 9d.; choice, 14s. 9d.; McIntosh Red, 16s. 6d., 15s. 6d. and 14s. 6d.; York Imperial, 26s. to 30s. per barrel; Kings, 25s. to 30s.; Wealthy, 28s. to 36s.; Lord Derby, 10s. per half-barrel, and Bramley's Seedling, 11s. Doyenné du Comice Pears sold at 25s. to 27s.; Winter Nelis, 21s. to 24s.; Beurré d'Anjou, 20s.; Keiffer, 12s. 6d. to 15s.; and Conference, 6d. per lb. Grape Fruits, Blue Goose, 80's and 96's, made 38s. 6d.; Triangular brand, 80's, 34s.; 96's, 35s.; South African Oranges, 176's, 150's and 200's, 24s.; Gros Colmar Grapes, 3s. 6d. per lb.; Alicante, 2s. 6d.; Black Hamburgh, 2s.; Muscats, 4s. 6d.; Melons, 4s. 6d. each; Pineapples, 4s.; and Persimmons, 1s. per box.

In the vegetable section, French Beans averaged 8d. per lb.; Madeira Beans, 5s. per box; Tomatos, 9d. to 11d. per lb.; Mushrooms, 2s.; Cauliflowers, 4s. to 6s. per dozen; Cucumbers, 3s. to 5s.; Lettuces, 2s. to 2s. 6d. per box; Leeks, 6d. per bundle, and Brussels Sprouts, 5s. per half-pot.

GARDENING APPOINTMENTS.

Mr. E. Edwards, for the past two years foreman at Moreton Hall, Cheshire, and previously for four years at Hatfield, Temple Newsam, and Chiddington Castle, as Gardener to the Hon. W. G. A. Ormsby-Gore, Wootton House, Bedford. [Thanks for 2s. 6d. for the R.G.O.F. Box.—Eds.]

Mr. A. Munday, for the past seven-and-a-half years Gardener to A. Manners, Esq., Littleover Old Hall, Derby, as Gardener to P. Robinson, Esq., Park Hill, Egginton, Derby.

THE HARDY HEATHS
AND SOME OF THEIR NEARER ALLIES
By A. T. JOHNSON.
Price 3s. 9d. post free.

This little book, the second of the GARDENERS' CHRONICLE HANDBOOK series (of which "RHODODENDRONS" was the first) has met with a very warm reception from the gardening public, and deservedly so. Heather is always beautiful, whether it is viewed at a distance clothing the rugged sides of a hill, or seen at close quarters, each little purple bell standing out from the narrow foliage. The Heaths and their allies comprise countless varieties, all in their own way beautiful and all susceptible of naturalisation within certain wide limits. Those who have soil in which Heather grows naturally should read this book to learn of the delights and of the requirements of a Heather garden.

The New Forest.

EVERY now and then the Society which was formed with the object of preserving the New Forest finds itself obliged to utter warnings and exhortations and to point out ways in which the Forestry Commission, under whose charge we believe the New Forest now is, might aid in the preservation of this most beautiful region of southern England. In its most recent plaint, the Society calls the attention of the Forestry Commission to the need for repressing seedling "Firs" which bid fair to encroach on and destroy the open moors which are, paradoxically enough, one of the glories of the New Forest. None who has seen them of an evening with Heather, like purple smoke from smouldering fires, and Bracken, brilliant yellow on the drier and crimson on the wetter parts, would welcome the destruction of these wide open spaces in the Forest. Indeed—to ask this question is our object in referring to the subject now—is it not time for all this bickering about the New Forest to cease? The Forestry Commissioners, full of zeal for a cause which we have all at heart, casts its purposeful eye on the New Forest. Imagine the energetic young officer, fresh, perhaps, from Finland, paying his first visit to the Forest, and after observing the occasional Oaks and the frequent lack of trees, asking "Where is the New Forest?" Imagine, further, his quickened determination to show us what a forest should look like; soft-wooded trees growing into money is the ideal which fires him. Can it not be stated and declared once for all that none of this myopic efficiency is to be tolerated. The lovers of the forest, and they are legion, desire it to be kept as it is, with its barrenness, its bogginess and its beauty. Everything is being "improved"—well, at all events, leave loveliness out of the schedule. We suggest to the society which with such energy and success is defending the New Forest from its would-be saviours that they should obtain from the Forestry Commission a complete recantation of intention. If ever the Commission had the intention to make the New Forest a Pine and Fir, or even a mixed, forest, let them abandon it for ever. No one wants it. The revenue ultimately accruing from the rejuvenated forest would not solace the sorrows of anyone of the thousands of people who love it as it is and for what it is—a sanctuary for man and bird and beast and flower. Let the forest, therefore, revert back to the conservators, whoever they were, who so well understood the feelings of those who frequented the forest, and who consistently left it alone. The Forestry Commission is a business body interested in growing profitable timber. That is a worthy avocation, the strenuous pursuit of which—in proper time and place—we all applaud. But the New Forest is not the proper place, and now is not the appointed time. So long as the forest remains under the charge of a Forestry Commission, unfriendly, efficient hands will always itch to be planting it with "Firs" and making it remunerative. They must be made to understand that it is more remunerative as it is than ever they can make it. Perchance, when they realise that the return the forest gives is paid not in cash but in kind—in kindly welcome, in the bestowal of peace and in the sweets of solitude, they will once for all cease from troubling the New Forest with their good intentions, and it and we shall be at rest! Best off it would be if, with good grace, the Commissioners would make the management of the New Forest over to the society which holds retreats and sanctuaries in trust for the public and does not seek to turn them into money-making concerns or even to improve them agriculturally—for marsh and heath and barren land are all Nature's children, very feckless, but lovely—and man does not live by bread alone.

Preservation of West Wycombe.—In connection with its self-appointed task of purchasing and preserving the village of West Wycombe, Buckinghamshire, the Council of the Royal Society of Arts proposes to issue very shortly an appeal booklet descriptive of the village and the aims of those undertaking the work of preserving its old world beauty and conditions. This booklet will contain an appeal for funds and Her Majesty the Queen has shown her interest in the Society's efforts by accepting an advance copy of the publication. Through the generosity of Lady Binning, a house not previously available has been acquired, and this will be used as a guest house and also as a centre whence information may be obtained concerning the village, its history and activities.

Preservation of Rural England.—On Wednesday, November 20, Mr. P. Morley Horder will deliver a lecture on "The Protection of Rural England," at the Royal Society of Arts, John Street, Adelphi, London, W.C.2, at 8 p.m. On December 4, at the same hour and place, Mr. Harry H. Peach, Hon. Secretary of the Council for the Preservation of Rural England Exhibition Committee, will lecture on "The Advertiser and the Disfigurement of Town and Countryside: Criticisms and Suggestions." The chair will be taken on this occasion by Sir Lawrence Weaver, K.B.E.

Demonstration of Advance of Plant Science.—With a view to discovering the best means whereby the advances made in plant science during the past one hundred years may be demonstrated effectively at the Century of Progress Exhibition, to be held in Chicago in 1933, eight leading botanists of America have been selected by Dr. Daniel T. MacDougal, of the Desert Laboratory of the Carnegie Institute, at Tucson, Arizona, to constitute a Committee which will consider the subject. The botanists selected are:—Dr. C. S. Gager, Brooklyn Botanical Gardens; Professor E. M. East, Bussy Institute, Boston; Dr. George T. Moore, Missouri Botanical Gardens, St. Louis; Professor H. P. Brown, Syracuse University; Professor J. Arthur Harris, University of Minnesota; Dr. E. D. Merrill, University of California; Professor J. B. Overton, University of Wisconsin, and Professor E. J. Kraus, University of Chicago.

Markeaton Park, Derby—Upon the provisional promise by the Derby Corporation to purchase, for £18,000, one-hundred-and-eighty acres of Markeaton Park, situated on the outskirts of the town, for the use of the public, the Rev. W. G. Clark-Maxwell, present owner of the estate, has promised to present the borough with the mansion therein.

The National Mark.—A booklet describing the extent to which the National Mark has been applied as a means of identification of home-grown agricultural produce, and the grades into which various kinds of produce are divided, has been prepared by the Ministry of Agriculture and issued by the Empire Marketing Board.

Window Gardens in London.—In connection with the campaign it is organising to popularise window-boxes in London, the London Gardens Guild has made arrangements for a lecture on "The Construction and Cultivation of Window-boxes," to be given at Prince Henry's Room, 17, Fleet Street, on Tuesday, November 26, at 8 p.m., by Mr. W. Stewart, N.D.H., Superintendent of the Royal Hospital Gardens. Admission is free.

American grown Narcissus Bulbs.—An interesting reflection, by implication, on American-grown Narcissus bulbs is found in a report of the School Garden Association of New York. This Association distributed 265,000 Paper White Narcissus bulbs to various schools last year, and a similar number in several previous years, but this year, owing to prohibition, American bulbs had to be used, and these showed so great a lack of uniformity that two schools, on adjoining blocks, reported entirely different results. For the present season the Association has arranged to obtain bulbs from different bulb-growing districts in the United States with a view to making comparisons.

Oaks in the Arnold Arboretum.—Oaks, best loved of trees by the Anglo-Saxon race, are the glory of northern forests. They have been associated with our history from immemorial time and the veriest tyro among tree lovers recognises an Oak at a glance. They form the genus Quercus and the members are widely distributed through northern regions, dipping into the tropics of both hemispheres. A majority of the species are evergreen, quite a few of which are natives of North America, but not a single evergreen Oak has proved hardy in the Arnold Arboretum (U.S.A). This is a pity, since one and all are beautiful umbrageous trees, none more so than the Holm Oak of Europe (Quercus Ilex), of which Kew Gardens boasts magnificent specimens. In North America and Canada some eighty-five species, of which twenty-eight are shrubs, and about sixty natural hybrids, are recognised. In the Arnold Arboretum sixty species and hybrids are successfully grown, the collection being, perhaps, the finest of the tree groups. New England is well represented in Oak species; in the Arboretum itself six are native, and Oaks are the principal feature of the mixed woods which clothe its low, rocky hills. When the Arboretum was founded in 1872, the Oak trees, through poverty of soil and excessive pasturage, showed marked signs of deterioration, many of them were stag-headed and dying at the top. Professor C. S. Sargent submitted them to the Des Cars' system of pruning, which consists of thinning out the lesser and pollarding the main branches. The beneficial result of this treatment is remarkable, especially among the White Oaks; indeed, it is difficult to tell without close inspection that they have been submitted to drastic pruning. In addition to the native species all that will withstand the climate are flourishing and there are trees now sixty feet and more tall, raised from seeds planted about fifty years ago. The idea is current that Oaks grow slowly, but the experience of the Arboretum is that they grow faster than the majority of hardwood trees. The erroneous notion of slow growth is probably responsible for their being much neglected by nurserymen. Their beauty as specimen trees for lawn and meadow is obvious to all, and their value as roadside trees is well demonstrated by the magnificent avenues of Red Oak which line the Parkway in the vicinity of Jamaica Pond. The best way of raising Oaks is by planting the acorns in flats so soon as they are ripe and transplanting the seedlings when a few inches high. As Oaks form a stout tap-rot, it is necessary to transplant them frequently in order to develop a fibrous root system. If properly grown from their youth, most of the Oaks transplant with ease but some, the common White Oak in particular, are notoriously difficult to move. Oaks, with their stout boles, rugged bark, massive branches and widespreading crowns, are beautiful at all seasons of the year. In the brilliancy of their autumn tints they are not excelled by any trees, and the soft greens, greys and pinks of their unfolding foliage and flowers is one of spring's greatest delights.

Roses at the Lord Mayor's Banquet.—Messrs. Benjamin R. Cant and Sons, Ltd., were again honoured this year by supplying the cut Roses for the floral decorations at the Lord Mayor's Banquet, at the Guildhall, on November 9. The principal varieties supplied were Shot Silk, Emma Wright, Madame Butterfly, Mrs. Beatty, Ophelia, Padre, Etoile de Hollande, Los Angeles and Diana Cant.

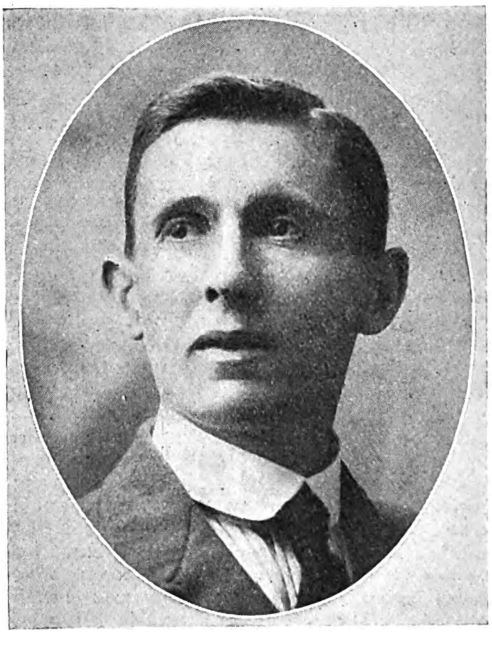
Iris Society.—The seventh Annual General Meeting of this Society will be held at the Grosvenor Hotel, Victoria Street, S.W.1, on Wednesday, November 20, at 6.15 p.m. The meeting will be followed by Dinner at 7.45 p.m. (morning dress), at 10s. 6d. per head, exclusive of wines.

Storing Brussels Sprouts.—Although we have no need to store Brussels Sprouts during the winter in this country, such a need exists in the colder parts of the United States of America, where the advice given is to store them in much the same way as Cabbages, *i.e.*, cut them to the ground, set them upright, closely together, without crowding, and lightly cover them (in a cellar ?) with seaweed or other light, coarse material. A heavy covering must be avoided, and although light freezing will not injure the crop, the Sprouts must not be handled while frozen; alternate freezing and thawing is ruinous.

British Carnation Society.—This Society's Autumn Floral Meeting will be held at the Royal Horticultural Society's Hall on November 20 and 21; the Annual Dinner will be held at the Restaurant Frascati, on November 20, at 6.30 for 7 p.m. Visitors to these functions are reminded that the railway companies offer cheap fares to London on these dates from many centres; further information may be obtained from the Hon. Secretary, Mr. F. W. Alesworth, 17, Avenue Road, Isleworth, or from the railway companies.

National Playing Fields Association.—The Annual Dinner of the National Playing Fields Association took place at the Hotel Cecil on November 12, the Duke of York presiding. In his speech, the Duke referred to the fact that the Association now had forty-three county branches and numerous local branches, and that a National Committee had been set up in Scotland, a branch having also been formed in Northern Ireland. A lay-out department had been established, to give local authorities expert advice in the designing of recreation grounds. Six-hundred-and-fifty gifts of land had been received, and many donations in money, including £200,000 from the Carnegie Trustees. One of the many schemes on foot would ensure the provision of large playing fields in East London, to which Mr. Samuel Courtauld had guaranteed £10,000.

Mr. James M. Grant.—Born at Rothie-Norman, Aberdeenshire, where his father was gardener for over forty years, Mr. James M. Grant already had a good knowledge of plants ere he commenced his gardening career at Aberlour House, Banffshire, where he served for five years, gaining a good all-round experience, both outside and under glass. After leaving Aberlour House he went to Houston House Gardens, Renfrewshire, as journeyman, where the cultivation of vegetables was carried on skilfully, and where fruits under glass were grown well and exhibited successfully at Glasgow. Seeking further experience, Mr. Grant obtained a post in the Edinburgh Botanic Garden, under the late Professor Sir Isaac Bayley Balfour; here he passed through the various departments and attended the classes arranged for young gardeners. The war came, and he served in France but returned to Edinburgh on the cessation of hostilities. Very soon, however, he was appointed to the charge of the trees and shrubs in the Canadian Government Park, at Niagara Falls. In 1921 he returned from Canada to take charge of the late Mr. Osgood McKenzie's gardens at Invereive, Pooleive, Ross-shire, where the collection of trees and shrubs was a particularly good one. Later, Mr. Grant came south to become gardener to W. J. H. Whittall, Esq., at Grayswood Hill, Haslemere, where also there is an excellent collection of the rarer trees and shrubs. At Grayswood Hill, Mr. Grant has carried out considerable alterations and added a goodly collection of Liliums. A very interesting feature of the Grayswood estate is a large orchard, on the greensand, containing over two-hundred-and-thirty varieties of Apples; Mr. Whittall takes a very keen interest in this orchard and at each of the past three Fruit Shows held by the Royal Horticultural Society, a Hogg Memorial Medal has been awarded to collections of fruits from it. This orchard is probably unique in regard to the number of varieties of Apples grown in a private establishment.



MR. JAMES M. GRANT.

Distribution of Tung-oil Seeds from Kew.—The Empire Marketing Board has, we learn, approved a grant to the Royal Botanic Gardens, Kew, for the purpose of distributing Tung-oil seeds to various parts of the British Empire with a view to encouraging its production within the Empire. China had, until recently, the monopoly of the Tung-oil production, but since the war it has been produced successfully in America. As the demand for Tung-oil, an essential ingredient of certain types of varnish, is increasing, and the supplies from China fluctuate greatly and are of irregular quality, seeds have been distributed from Kew to various countries throughout the Empire, and promising trials in its production have been carried out in Kenya, Australia, New Zealand, South Africa, India, Ceylon, Assam, the West Indies, Malaya, Burma, Hong-Kong, Cyprus, Tanganyika and Palestine. The grant by the Empire Marketing Board will provide for the further distribution of seeds from Kew, and for the purchase of Tung fruits for experimental purposes in Great Britain.

Royal Horticultural Society of Aberdeen.—The Annual Meeting of this Society was held in Aberdeen on Saturday, November 9. Mr. W. B. Clark, Superintendent of Aberdeen's city parks, occupied the chair. The annual report referred to in our issue of the 2nd inst., was read and adopted. Lord Provost Rust, the newly-elected civic head of the city, was elected Honorary President, and the Vice-Honorary Presidents were re-elected. Sir Thomas Jaffrey, who has been a warm friend to the Society, was reappointed Chairman of Directors, and Mr. J. B. Rennett will continue to look after the financial and secretarial duties. There were seven vacancies to fill in the directorate, the rules demanding the retirement of so many directors annually. A vote, taken by ballot, resulted in the following seven gentlemen being elected: Messrs. William Cumming, John Cameron, George Tocher, James McDonald, George Harper, Frank Fernie and James Duncan.

New York Garden Competition.—The increasing interest taken in gardening in the United States is reflected in garden competitions, many of which have been held during this year. According to *Horticulture* (America), one of the most extensive of these competitions was under the direction of the *New York World*, and carried entries reaching a total of 4,200. An idea of the magnitude of the entries may be had from the fact that twenty-four judges, travelling in teams of three, required three days in order to visit the gardens selected by a previous elimination committee. More than seven hundred local prizes were awarded. Mr. J. I. Lyle, of West Seventh Street, Plainfield, New Jersey, was the winner of the first prize award in the open class which included gardens of 15,000 square feet or more. In the class limited to smaller gardens, Mr. Charles Johnson, Euclid Street, Forest Hills, New York, was first prize winner.

"The Flowering Plants of South Africa."—The plants figured and described in No. 34, Vol. IX, of *The Flowering Plants of South Africa*, recently issued, are Exochaenium grande (t. 331), Kleinia articulata (t. 332), Aloe africana (t. 333), Pavonia Meyeri (t. 334), Pelargonium longifolium var. longiflorum (t. 335), Loranthus rubromarginatus (t. 336), Gladiolus Ludwigii (t. 337), Sparaxis bulbifera var. violacea (t. 338), Melasma orobanchoides (t. 339), and Kniphofia linearifolia (t. 340). Exochaenium grande is the first South African member of Gentianaceae figured in this work, although nine genera of this Natural Order and about one hundred species are recorded as occurring in South Africa, the largest genus, with over seventy species, being Sebaea. The eleven species of Exochaenium recorded are all tropical African, E. grande extending into South Africa. It is an annual, common in grass veld, with biscuit-yellow flowers, and it is suggested it might appropriately be called the South African Primrose. If South Africa must have a Primrose no doubt this subject is a suitable claimant to the title, as there is a superficial likeness between its flowers and those of our Primrose, although there the likeness finishes. The dividing line between Senecio and Kleinia is very obscure, and some authorities consider the latter should be absorbed by the former, but in the work under review the known name of Kleinia articulata, a plant of fleshy growth and of no horticultural merit other than as a novelty, is used in preference to the adoption of Senecio as the generic name. Aloe africana, which has large, saw-edged, stout and thick leaves, and produces large, closely-packed spikes of tubular, orange-yellow flowers, is confined to the coastal belt of the Cape Province, and occurs plentifully around Port Elizabeth and Uitenhage; it is figured in the *Botanical Magazine*, t. 2,517. The Natural Order Malvaceae is represented for the first time in *The Flowering Plants of South Africa* by Pavonia Meyeri, an attractive sub-herbaceous plant which attains a height of up to four feet, has highly aromatic foliage and dainty, pale pink flowers, and grows in the vicinity of water and in the shade of trees near Pretoria, in the Fountains Valley. Pelargonium longifolium var. longiflorum belongs to the section Hoarea of the genus, the members of which are stemless, have tuberous roots and four- or five-petalled flowers. It is a curious plant but not very ornamental. Loranthus rubromarginatus is a curious parasitic plant, related to Viscum (Mistleto), not particular as to its host, and recorded as parasitic on several species of trees. It is very conspicuous when in full bloom, its long, tubular, reddish flowers being produced in clusters along the stems of the host plant. The green bracts are very conspicuous in the flower spikes of Gladiolus Ludwigii, and as the flowers are dull creamy-lavender, this species does not compare favourably with many others. Sparaxis bulbifera var. violacea, however, is a charming plant of diminutive stature and bears rather large, rich rosy-purple flowers. S. bulbifera varies considerably in the colour of its flowers, but the type is stated to be yellow. Melasma orobanchoides is a parasitic Schrophulariad. Dr. Bolus recorded it as parasitic on a species of Rhus, while the specimen from which the plate was prepared was found on the roots of Hypoestes verticillaris. It has also been recorded as parasitic on cultivated crops, notably Legumes, and is regarded as a potential danger to growers of Leguminous crops. Kniphofia linearifolia carries its tubular flowers, opening reddish and changing to yellow with age, in a dense head at the summit of a leafless, erect stalk 30 cm. long; it would not appear to be of much garden value.

Swanley Horticultural College.—An ordinary General Meeting of the members of the Horticultural College, Swanley, will be held at 29, Bryanston Court, Upper George Street, London, W.1, on Tuesday, November 19, at 4 p.m.

Appointments for the Ensuing Week.—Monday, November 18: Harrogate and District Horticultural Association's meeting; National Chrysanthemum Society's Floral and Executive Committees meet. Tuesday, November 19: Royal Horticultural Society's Nut Competition; Winchester Horticultural Society's meeting. Wednesday, November 20: British Carnation Society's Show (two days); Newcastle and District Horticultural Society's Chrysanthemum Show (two days); Hull and East Riding Chrysanthemum Society's Exhibition (two days); Harrogate and District Horticultural Association's Show (two days); Ayr Chrysanthemum Society's Exhibition; Wimbledon Gardeners' Society's meeting. Thursday, November 21: Ipswich Gardeners' Association's meeting; Norfolk and Norwich Horticultural Society's Chrysanthemum Show (three days). Friday, November 22: Dundee Horticultural Society's Chrysanthemum Exhibition (two days). Saturday, November 23: Leeds Paxton Society's Potato Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Preservation of Dahlia Roots.*—Being fond of good Dahlias, and grieved at the frequent losses that come under my notice, I beg to commend to the attention of those who too often have to lament the loss of their favourites, the following effective method of preserving their roots. The tops being killed by the autumn frosts, and thus become unsightly, must be cut away, leaving the roots undisturbed for several weeks in order to feed the nascent buds destined to break the following spring. For, if at the time of removing the plants from the ground these buds are immature, there is great probability that the tubers will perish before the spring, or should their vitality remain, there will be found a difficulty, if not an impossibility of getting them to "break." The next business is to lift the plants from the ground, and in doing this the greatest care should be taken to preserve their fibrous roots, for the plants require constant nourishment. A number of these rootlets will, however, under the most careful handling, be broken off, and the supply of sap interrupted until new roots are made; but with those plants that have well-swollen buds their reproduction is soon effected. When the tubers are raised from the ground they should immediately be transferred to their winter quarters, where their fibrous roots must be carefully spread upon a thin layer of sand or earth, and at once covered with about an inch of the same, leaving the greater portion of the tuber bare. During winter they should be kept slightly moistened. For wintering these tubers there is, perhaps (unless an especial place is provided for them), no better place than under the stage of a cool greenhouse; but, whatever place may be assigned them, it is indispensable that it admits a moderate amount of light; is kept cool, but above the freezing point, and that the atmosphere is such as suits growing plants generally; alike free from both saturation and dryness, which will with equal certainty, engender putrefaction.—*W.*, *Gard. Chron.*, *November* 18, 1854.

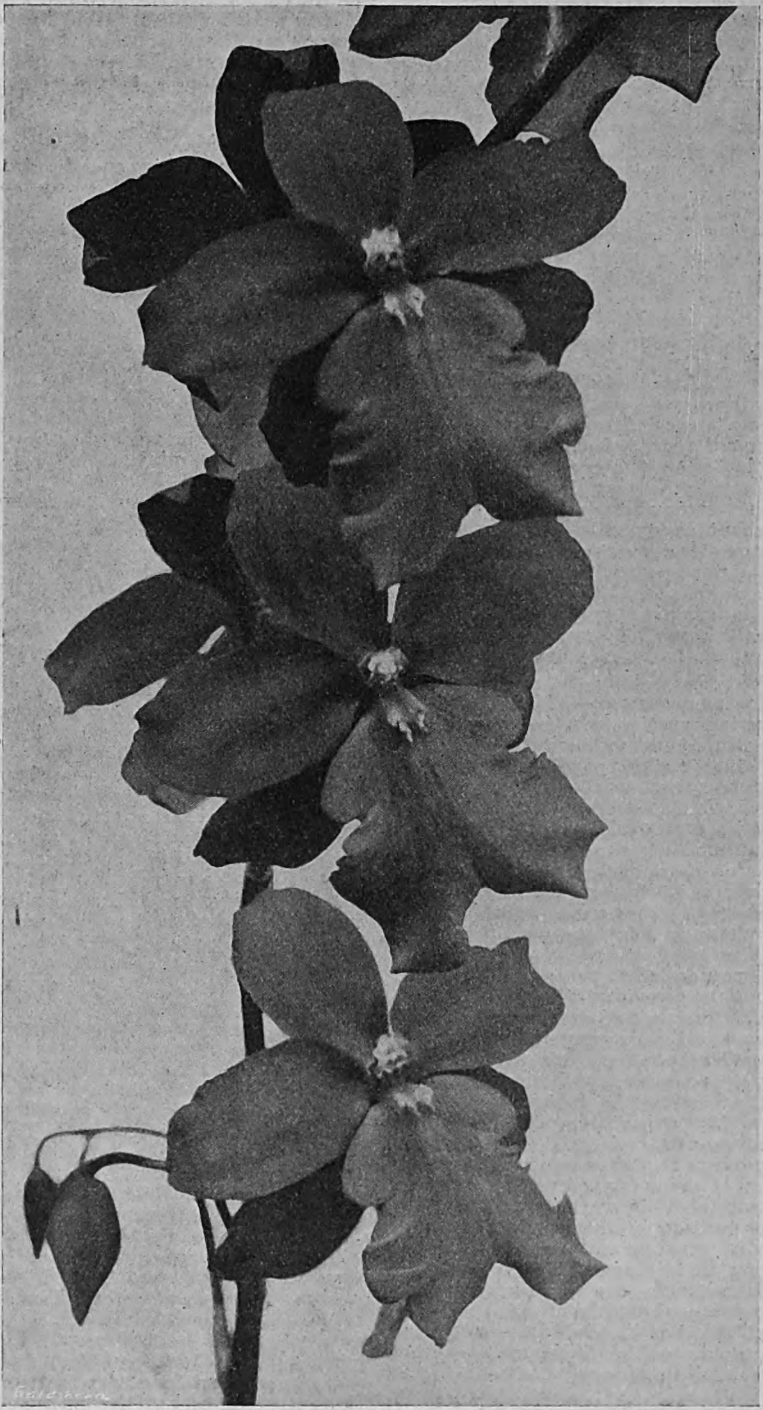


FIG. 173.—VUYLSTEKEARA ETNA, STAMPERLAND VAR.

R.H.S. First Class Certificate, November 5; flowers crimson and cerise. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly (see p. 372).

Publications Received.—*Die Gartenstauden* (Lieferung 2). By H. R. Wehrhahn. In about ten parts, price of each 5.20 Rm. Berlin, Verlag von Paul Parey.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Aerides, Vandas and Angraecums.—These warm-house Orchids, which revel in plenty of heat and moisture during the summer and autumn months, are now approaching the end of their growing season and do not require so much moisture, either in the atmosphere or at the roots. The amount afforded should be gradually reduced as the distinct, white film covers the roots; when this is accomplished, very little water will suffice to prevent the leaves shrivelling and keep the plants in a normally plump condition. Sufficient air should be admitted on all favourable occasions to secure growths of firm texture; this, with exposure to all the light available at this season, should assist in hardening the growths and so enable the plants to pass through the dull winter months successfully. Soft and flabby growths prove easy victims to the unsightly blackspot disease. Many other occupants of the warm house, such as Acinetas, Barkerias, Stanhopeas, Mormodes, etc., will, on completion of their seasonal growth, only require watering at long intervals to keep them in a plump condition during the partial resting period. Opportunity should be taken to thoroughly overhaul the plants at this season, and if scale or other insect pests are detected they should be removed with the aid of a small brush and sponge and a safe solution of an approved insecticide, care being taken to avoid any injury to the "eyes" or growing points at the base of the pseudo-bulbs, also not to injure the leaves by excessive rubbing.

Dendrobium acuminatum.—This attractive summer-flowering species requires very little shade at any time, and to plants now in full growth, the lightest position possible in the warm-house should be given, and a free circulation of air maintained on all favourable occasions. Large quantities of water are not required at any time, but moisture should be afforded to the roots at this stage each time the compost approaches dryness. When growth is completed, very little water, at long intervals, should suffice to keep the plants in a healthy condition until the flower spikes are observed growing from the apices of the pseudo-bulbs, when an increased quantity should be given each time the compost becomes dry. During the warmer months of the year frequent light syringings with tepid water is beneficial, but at this season light spraying only should be given on favourable bright mornings so as to allow the foliage to become dry before night. Other Dendrobiums which are still in full growth, such as D. Brymerianum and the tall-growing D. Dalhousieanum, together with members of the evergreen section, such as D. densiflorum and its varieties, should be given a light position in the warm house and encouraged by generous treatment to assist in building up their pseudo-bulbs so soon as possible. When these are complete, cooler and drier conditions should be afforded them in the intermediate house, and just sufficient moisture applied to the roots to keep the pseudo-bulbs in a plump condition.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Pruning Fruit Trees.—To become quite competent in the art of pruning hardy fruit trees it is absolutely essential that the pruner should be thoroughly acquainted with the whole make-up of the tree. The nature of the soil, too, in which the tree is growing should have due consideration, for it is obvious that a tree or bush growing in a deep, fertile loam should be treated differently from the same variety growing in a rather poor soil. The pruner should realise there can be no hard and fast method of pruning. If he has a knowledge of the rootstock on which his trees are growing, so much the better. It is clear, from the pruning trials at East Malling, that the habit of the tree, its precocity, its fruitfulness, its fruiting season, its health, and in consequence, its power of resisting disease, can all be influenced by the rootstock. He should realise, too, that each variety has its own habit of growth and fruiting, and to achieve the maximum results, the pruning should be adapted to the variety. Pruning delays fruiting, but increases the size of the fruits and decreases the liability of diseases such as scab, canker and mildew. For the production of larger fruits on old trees, the judicious thinning of the branches becomes more and more justified with age.

Pruning Bush Apples and Pears.—The pruning of these trees is one of the most interesting and important of garden operations. It is an operation which calls for close study and much foresight, as it is absolutely essential that each variety, and in many cases each tree, should be studied, and varied pruning methods adopted, to suit the habit and fruiting of each. The chief objects of pruning are to assist the tree to attain any desired form, to encourage the formation of fruit buds, and to improve the flavour, quality and size of the fruits by admitting air and sunlight to all parts of the tree. The method of pruning should change with the development of the tree. For the first four or five years after planting, the aim of the cultivator should be to build up the main branch system of the tree. Then follows a period of about the same number of years, in which the head of the tree continues to develop, but the aim of the pruner is to bring the tree into a crop-bearing state. So soon as the tree has been formed and has commenced to crop, the first and second methods of pruning should gradually give place to the thinning out of superfluous branches, and to judicious manuring, to ensure sufficient vigour for the production of a healthy tree, and heavy crops of large fruits throughout a long life. In the first stage of the young tree the branches should be well-spaced out, and the centre of the tree kept open to admit all the sunlight possible, and to facilitate the operation of spraying and the perfect development of spur-growths and fruits. This spacing out should not be carried to extremes, or valuable space may be lost, but a distance of sixteen to eighteen inches should be allowed from tip to tip of the branches when they have grown to a length of four feet. The leader shoots, at this time, should be cut back to two prominent side buds, twelve to fifteen inches above last year's point of pruning; the buds should produce strong growths, and thus form two fruiting branches where the circumference is greatest. At all other times the pruning of the leader shoots should be to an outside bud, or to a bud pointing in the direction the grower wishes the future growth to take. The direction of the future shoot can be influenced by the way in which the cut is made, whether close to, or slightly above the bud; if close to the bud the shoot will assume much the same direction as the portion cut away; but if an inch or so of stub is left above the bud, the future growth will assume an outward angle, and in very upright-growing trees this method is advantageous. All side-shoots, or laterals, formed on last year's wood should be cut back to form fruiting spurs, and the number of buds retained should vary according to the strength of the shoot. Those situated nearest the top will be strongest and should be pruned rather more lightly than those further back. The strongest should be cut back to four visible eyes, the remainder to three or two, according to their strength. Usually, the top two eyes on the strongest shoots will grow out, but the eyes immediately behind these will become "dards" (prospective, but immature, fruit buds). The object in the next year's pruning is to stimulate these dards, and convert them into fruit buds. The safest way to accomplish this is to prune each of the shoots back to one visible eye which will act as a sap-drawer and safety-valve while the dards are being stimulated into fruit buds. If this pruning is too light, say, to two or three eyes, the dards remain as they were, undeveloped, or may even die out. Once the dards are converted into fruit buds, the shoots acting as safety-valves may still be pruned closely or removed altogether. Wood shoots often arise from fully developed fruit spurs. These should be cut back in the same manner, to one visible eye. This eye will grow out and act as a sap-drawer, and use up superfluous food-stuffs, while the dards and fruit buds are being stimulated, but not forced into growth. Every branch should be treated like a cordon, but every tree should be treated on its own merits, and due consideration taken of its behaviour to last year's pruning.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Eucharis grandiflora.—At one time no stove was considered complete unless this favourite old plant was included in the collection, but now it is by no means so extensively grown. However, it is a very useful subject to grow where a supply of white flowers is in demand, a point in its favour being that it may be had in flower more or less all the year round. This is effected by resting the plants at intervals by keeping them somewhat on the dry side and in a slightly lower temperature, but in both conditions moderation is to be recommended. E. grandiflora is an evergreen, therefore it should not be dried off completely. Plants that have been rested may be introduced to a warm house, preferably one in which ample bottom-heat can be maintained. It succeeds either grown in pots or planted out in borders near the hot-water pipes. I have seen very good results obtained from the latter method. This plant, when in full growth, enjoys a temperature of 65° to 70°, and when plunged, a bottom heat of 80° is to be recommended.

Climbing Plants.—It is imperative at this season of the year to secure the maximum amount of light for plants growing in structures where climbing plants are allowed to ramble at will during the summer months, therefore it may be necessary to thin out and tie in the shoots of any climbing plants that are all overcrowded. At the same time, any insect pests on the plants should be dealt with and when opportunity occurs scrub down all the glass and woodwork.

Camellias.—When in good health Camellias often set far too many flower buds and if this happens the clusters should be thinned to a single bud. Bud dropping is sometimes caused by some cultural error, such as excessive dryness at the roots, therefore the soil should be kept in an even state of moistness.

Freesias.—The earliest Freesias are now growing freely, and to prevent the young shoots being broken they should be supported by placing four neat stakes in each receptacle, and tying Raffia around these at intervals as required. The plants should be grown under cool conditions and so near the roof-glass as possible. A little liquid manure, given alternately with clear water, should prove helpful to the roots. The later plants should be grown so sturdily as possible by avoiding high temperatures and admitting air on all possible occasions.

Codiaeums (Crotons).—Where shading has been used on houses in which Codiaeums are growing during the summer months, this should be removed. The plants need all the light possible from now onwards, and by judicious feeding of the roots with liquid manure, which should be applied each week, the development and colouring of the foliage will be assisted.

Anchusa italica.—This makes an excellent subject for the decoration of the conservatory or unheated greenhouse. Plants that have been raised from seeds should be lifted and placed in the most suitable-sized pots, plunging the receptacles out-of-doors until they are required. They should flower several weeks before those growing in the open garden. Do not try to force this plant in strong heat, as this may only result in failure.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

The Orchard House.—If very early forcing is contemplated, the house usually devoted to this work should be cleansed, as the time is at hand for placing the trees in position. When selecting Peaches and Nectarines for this purpose, only early-fruiting varieties should be chosen, and the trees should be well set with buds and have thoroughly ripe growths; the pots—not too large—should be well filled with healthy roots. Duke of York and James Walker are considered good forcing Peaches, while Cardinal and Early Rivers are good Nectarines for this purpose. The heads of the trees should be kept well up to the glass and allowed plenty of room for their full development; mild bottom-heat being a great help, standing them on inverted pots, or bricks, will allow for the placing of fermenting leaves about them. If well disbudded in the spring and all superfluous shoots were removed after the crop was gathered, the trees should require very little pruning; still, they should be looked over, as some of the strong shoots may be the better for being cut back to triple buds, twelve or fifteen inches from their base, while others may require hard pruning to ensure a relay of young growths for next season. Weak side-shoots should be left full length until the fruits are set and the young growths are growing freely. Care in the retention of wood-buds should not be overlooked as it is easy to render a growth useless by their removal. When this work is finished the house cannot be kept too cool and airy when the weather is not severe, but the roots of the trees should never feel the lack of water.

Potting Fruit Trees.—If potting has been neglected, it is not too late to complete this work. Maiden trees may still be lifted and potted and plunged in open borders. In the selection of orchard house trees no second class variety should be chosen, as it is better to have a dozen trees of one good sort than a dozen distinct varieties. Figs in pots should be stored in a place where they can be kept fairly dry and safe from frost.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Planting Trees and Shrubs.—November is the most suitable month of the whole year in which to plant deciduous trees and shrubs, therefore planting operations should be the most important occupation at the present time. More trees and shrubs are ruined by bad planting than by by any other means. Provided the beds or borders have been trenched as previously advised holes should be opened wide enough to accommodate the roots without in any way twisting or doubling them up. If the soil is poor, have a supply of old loam and leaf-soil at hand and give each tree or shrub a plentiful supply when planting. Have everything in readiness for planting before the trees arrive, and endeavour to complete the planting so expeditiously as possible, so that they may have the advantage of the warmth left in the soil, and be in position before work is held up by autumn rains or frosts. Where space permits, a Heath garden will be found of great interest at practically all seasons of the year. There are numerous Heaths available, and if a wise selection is made there should be bloom practically throughout the year. A sandy loam is as satisfactory for the majority of these Heaths as a peaty soil. On soils of a heavy texture it is advisable to incorporate a plentiful supply of decayed leaves and sharp sand as the site is being prepared; needless to state, these Heaths will not grow on soils charged with lime, with the exception of Erica carnea and its numerous hybrids; which do not resent a certain amount of lime in the oil. E. carnea and its numerous varieties give a continuous display for the first five months of the year, and may be supplemented by E. arborea, E. a. var. alpina and E. mediterranea and its varieties. These are followed during the summer months by numerous varieties of E. cinerea and then by varieties of the common Heather, of which there are many good sorts. For the autumn there is E. vagans and its several varieties. These usually bloom well into November and by that time the colour is beginning to show in the E. carnea section again.

Lobelias.—Herbaceous Lobelias are fairly hardy, but unless under specially favourable conditions they should be lifted about this time every year and placed in cold frames for the winter, packing a mixture of leaf-soil and sharp sand about their roots. Plenty of air should be admitted to them on all favourable occasions, and excessive moisture and frosts should be guarded against.

Montbretias.—The newer hybrid Montbretias should be lifted and the corms wintered in frames from which frost can be excluded. A great advance has been made during recent years in these useful border plants, and they are well worth the extra care required to carry them safely through the winter.

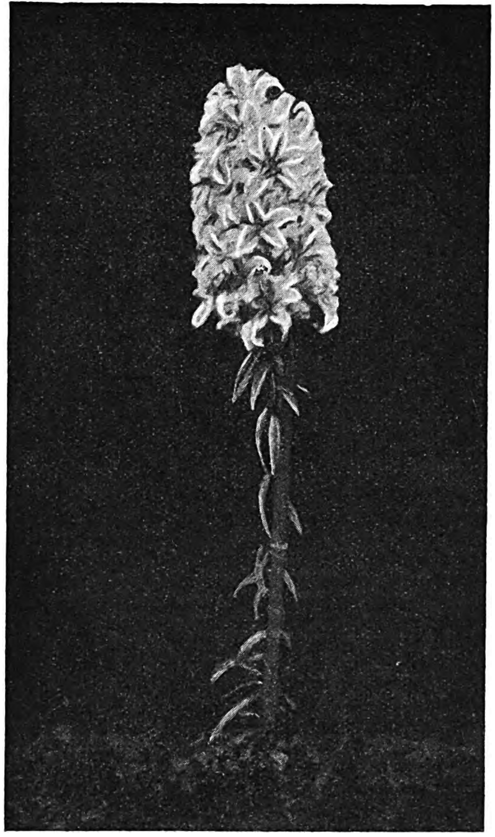

FIG. 174.—LILIUM AURATUM AT CRUMPSALL.
(see p. 391.)

Kniphofias.—These handsome plants contribute much to the brightness of the garden during late summer. In the north, and on wet, cold soils they, unfortunately, do not withstand the winter well without some protection; therefore it is advisable before the approach of hard weather to give them some protection. A few Spruce or Fir boughs around each clump, and with dry Bracken worked through them, should afford sufficient protection, and this method is neater than that of placing leaves around the crowns, as these are apt to be blown about.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Stachys tuberifera.—The tubers of Stachys tuberifera may now be lifted and stored in a cool, dry place, care being taken when lifting them as, being so small, they are easily overlooked. The tubers will keep for a considerable time if placed in a heap and covered with some thick material to exclude light and air.

Herbs.—Roots of Mint should be lifted and placed in boxes or pots, ready to be introduced into heat. Cuttings of Thyme and Sage may be inserted in five-inch pots; one dozen cuttings in each in fairly sandy soil. These should be well rooted by the end of March, when they may be planted out.

Winter Salads.—Where it is necessary to maintain a supply of so many salad plants as possible, an occasional sowing of Mustard and Cress should be made. Regular and further plantings of Lettuces should be made at once, filling any spare frames and boxes with them. Chicory may be lifted and the roots stored and placed in the forcing house as required.

General Work.—Continue to clear off all spent crops and tidy up the ground as it becomes vacant in preparation for trenching and digging.

Endive.—Plants that are fully grown may now be lifted and placed in frames fairly closely together. Others in the open may be tied up with raffia to bleach the centres, or nine-inch pots may be placed over them for the same purpose.

Winter Greens.—These, and especially Brussels Sprouts, should be examined and cleared of decayed leaves so that air may circulate freely between the plants and prevent damping and rotting of the buttons. The beds should be kept clear of weeds.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemount, Monkton, Ayrshire.

Asparagus Beds.—As the growths show signs of ripening off, whether by the action of frost, or naturally, they should be cut down, all weeds cleared, and a good heavy dressing of manure spread over the beds and dividing alleys; this affords a certain amount of protection in extreme weather, and provides nourishment at the same time.

Globe Artichokes.—These are rather tender in cold districts, and should be given a mulch to protect them. Very fresh strawy manure is suitable for this purpose in most cases, but on clay soils sifted ash is, perhaps, preferable, keeping the crowns comparatively dry, and at the same time protecting them from slugs. A few young crowns should be lifted, potted up, and placed in frames to ensure the maintenance of a stock should the winter be so severe as to destroy those in the beds.

Autumn-planted Cabbages.—Where there is difficulty in wintering these, and it has been fairly general in recent years, I find that a small mound of sifted ash placed around each plant is of the greatest assistance in bringing the plants safely through the winter. This protects them from slugs and keeps them steady where exposed to rough winds.

Fire Ash for Mulching.—Pyrethrums, Delphiniums and all plants of a herbaceous kind noted in previous winters as suffering from the ravages of slugs, should have a layer of sifted fire ash placed over the crowns, so soon as the plants are cut back. This also helps to improve the condition of heavy land if applied for a number of years, but the ash should be passed through a riddle of not more than half-an-inch mesh.

Early-flowering Chrysanthemums.—Sufficient plants of each variety should be lifted for stock, as in but few places can they be depended upon to winter well out-of-doors. Those selected should be shaken free of most of the soil and laid beneath frame lights or in an empty glass-house to dry. When well-dried, they should be placed in boxes or on the floor of a greenhouse and a little light soil placed among the roots, but not so much as to bury the collars of the stools; leaf-mould and sand in equal parts is ideal for this purpose. Very little water should be given them during the winter months, only enough to prevent excessive dryness being necessary, as cuttings are seldom wanted until March.

ALPINE GARDEN.

TWO PROSTRATE LINUMS.

For a choice position in the rock garden, the stony soil being sharply-drained and the aspect sunny, there are no pleasanter Flaxes of lowly growth than Linum alpinum and L. salsoloides var. nanum. The former comes very near to L. perenne, but it is much more slender in its stems and these, if not perfectly prostrate, have a tendency to spread laterally. The grey-green leaves are extremely fine, in keeping with the frail and delicate growths, and the latter bear at their tips nearly all the summer, loose clusters of flowers which, if not so large as those of L. perenne, are big for the size of the plant. The blossoms are a singularly clear, but pale, china-blue, showing, in my experience, very little variability.

The other plant named above is very unique in its entirely prostrate habit, both leaves and stems being so attenuated and so interwoven in a low, dense mat that they might suggest anything but a Flax. This grey-green, almost emerald, pad of verdure is adorned for several weeks in summer by flowers closely resembling those of the type. But these vase-shaped, pearl-white, dark-eyed blossoms are almost stemless and few plants are more attractive in refinement and dainty elegance than L. s. var. nanum, studded all over with these shell-pale flowers. A dry, hot ledge of very gritty soil is what this little plant enjoys and under such conditions it is quite reasonably hardy. Excessive winter wet it dislikes, and it is always well to keep a few cuttings in reserve for, winter losses apart, these Linums are not long-lived plants. *A. T. J.*

SEMPERVIVELLA ALBA.

I was greatly interested in the note by Mr. Ralph Arnold (p. 303). I may assure him that Sempervivella alba is hardier than he imagines, as it withstood the past winter here, without protection, while so many of our delicate and tender plants died. But one thing I would like to know is the origin of this plant; I have sought it in every way that seems possible, but without success. The source of my own plants is uncertain, therefore some light on the subject would be welcome for I do not like to have "heitmathlose" plants in my collection. *H. Correvon, Chêne-Bourg, Geneva.*

HEERIA ELEGANS.

The trailing growths of Heeria elegans make this subject well suited for the rock garden, and it is a most charming plant for that purpose.

It does not require any special cultural treatment in a lime-free soil to produce, during the summer, the brilliant crimson flowers that adorn it at a time when many of the familiar rock plants are past their best.

Heerias belong to the Natural Order Melastomaceae, but they cannot safely be regarded as hardy, even in mild localities, so that their preservation during the winter should be ensured. *Frederick Gooch.*

PARONYCHIAS.

The Nailworts belong to that strata of garden society which regards virtue above adornment. Thrifty, lowly, quiet and always kindly and respectful to their neighbours, these soberly-dressed little creatures have a winning way about them which appeals to many. Southerners as they are, often dwellers amid the burning aridity of the Ligurian Alps, they endure with commendable courage all the worst that our winters inflict upon them. This, provided they are given the poorest of stony soil, or mere crevices in some flagged walk or stone steps. Even the sun they all do not insist upon, their abounding good nature making the best of the most dismal prospects.

The Paronychias belong to the Natural Order Illebraceae. They are prostrate, creeping, perennial herbs forming dense mats of their finely-woven verdure. The tiny leaves and branches are hairy in all species that have come my way, and the plants may be anything from a grey to silvery-green. If they have no flowers to speak of they make amends for this by enclosing such as they have in silvery-white bracts. These latter, papery and gleaming with a pearly lustre, are by no means unattractive (especially under a pocket lens) and they are on view the greater part of summer and autumn, their delicate tissue blending with the silvered foliage in a soft iridescence.

The names of these gentle plants I have never had the leisure to unravel, but one of the most delightful is stated to be P. capitata, and this may be what I have as P. nivea, more upright than most, with very conspicuous bracts. P. pyrenaica (which is possibly P. serpyllifolia) drapes the end of an old stone trough with a net of silvery verdure finer and closer than that of Arenaria balearica, while matted about some steps in shade and sun are P. argentea and P. polygonifolia. All these names, however, are subject to a revision, which I hope to accomplish some day. Meanwhile, the modest charm of these engaging waifs is alone more than sufficient to justify their claims upon the affections of all who appreciate such things. *J.*

TREES AND SHRUBS.

PIERIS JAPONICA.

It says much for this fine shrub's hardiness that it endured the severe frosts of last winter in many places. Although we touched zero here, the foliage was uninjured and quite a fair number of flowers appeared in their due season. The late Mr. E. C. Buxton had a remarkably fine specimen in his Bettws-y-Coed garden and this bloomed every year with the utmost freedom in spite of the fact that it was open only to the north-east. Behind it, and entirely shading it from all but early morning sun, was an immense Douglas Fir whose outer branches doubtless helped to screen the shrub from frost. These facts may suggest possibilities to many who regard P. japonica as too tender for their locality. It is, however, not so much the shrub itself, but the blooms that are likely to suffer. This species would appear to be almost as hardy as P. floribunda, but the racemes of buds which form in autumn to expand from March, or earlier, to May, have to contend with the trials of winter, while the open blooms are, in their turn, liable to be cut by spring frosts.

P. japonica grows to eight or more feet, making a shapely bush usually well-furnished with branches to the ground. The evergreen, oblanceolate, leathery leaves are narrower and longer than those of the more familiar species mentioned, and of rather a paler green. The flowers are borne in beautiful clusters of pendulous racemes at the extremities of the twigs, the pitcher-shaped corollas, each over a quarter-of-an-inch long, being rosy-pink in the bud, changing to white. When the flowers are over the new growths are very attractive, both leaf and bark being a glossy reddish-bronze, but in this regard the shrub is not so handsome as P. formosa or P. Forestii.

P. japonica needs a light, warm, lime-free loam, preferably with some leaf-mould or peat. I find the best method of propagation is layering, and have had shrubs of this species raised by that means in flower when barely a foot tall. *N. Wales.*

INDOOR PLANTS.

SINNINGIA CAROLINAE.

Although less brilliant in colour than the many hybrids of Sinningia speciosa which, under their popular name of Gloxinia, are extensively cultivated in greenhouses, Sinningia Carolinae will always attract attention when in flower by reason of the quaint appearance of its blooms. It is also of interest to note that it is one of the parents of the bigeneric hybrid Gloxinia Tapeinotes.

S. Carolinae is an easily-grown stove or warm greenhouse herb, growing about fifteen inches high, with somewhat fleshy, square stems, clothed with opposite, ex-stipulate, lanceolate leaves about nine inches long, deep green in colour, tinged when aged, with bronze. The flowers, one-and-a-half inch long, are borne mostly in pairs in the axils of the leaves. The inflated, pouch-like corolla is white, with five yellowish limbs at the gaping mouth, the exterior of the corolla tube being densely covered with slender hairs.

Propagation of this subject is easily effected by cuttings, indeed, adventitious roots develop from the stems, when the plants are grown in the close, moist atmosphere of a stove. If the cuttings are rooted in early spring the plants should flower as they grow during the summer and early autumn. In its early stage of growth, S. Carolinae is unbranched, but towards the end of the season side-growths develop at the base of the stem. For decorative effect, the placing of several plants in each receptacle is recommended, and three plants in a six-inch pot will make a well-furnished specimen. *Jonathan Fiona.*

ARISTOLOCHIA ELEGANS.

Aristolochia elegans is one of the very best of its genus and deserves a place in every stove. It is a species hailing from Brazil and was first introduced to this country about the year 1883.

No description, however good, could quite portray the beauty of its very handsome blossoms. They are solitary, and borne from the axils of the leaves on rather long pedicels. The throat of the perianth tube is a pale greenish-yellow in colour, and the tube opens out into a shallow, heart-shaped cup about four inches in diameter. The background of this is white, and is exquisitely marked with veinings of purplish-brown, gradually shading deeper until they merge into a dark, half-circular band. This is about half-an-inch deep and ends abruptly at the entrance to the tube, showing it off to great advantage. The reniform-cordate leaves are about three inches long and broad, and are borne on petioles from one inch to two inches in length.

Pruning should be attended to each autumn or winter by cutting back severely the season's growth to just a few basal buds near the old stem. An increase of stock can be made quite easily by means of seeds, which the plant sets freely. *F. H. Wright, University Botanic Garden, Cambridge.*

BULB GARDEN.

CROCUS PULCHELLUS.

Crocus pulchellus is one of the most delightful of the autumn-flowering Crocuses, of which far too few are grown in gardens where the conditions are suitable. Like most of the family, C. pulchellus calls for a light soil and a sunny situation in our climate. Given these and a sheltered spot, it is likely to give unbounded delight to all who love the flowers of autumn and who seek to brighten their gardens with such gems as this Crocus. Its flowers are not large, it is true, but they are charming in every way. That this praise is justified may be learned from what Farrer wrote in his *English Rock Garden*, where he calls it "one of the darlings of the family," and adds that it is good enough for the "choicest slopes and beds of the choicest plot." It is of a delightful delicate lavender, beautifully lined and with orange spots at the base.

There is also a lovely white form, and the type varies from seeds. Years ago, in a seaside garden, I had a charming group which owed its being to a few corms sent me from Asia Minor. These plants seeded, and the seedlings were allowed to remain where they sprung up. The result was delightful—an informal group composed of many lovely cups of delicate colouring. Like other autumn-flowering Crocus species, C. pulchellus should be planted in July or early August, in sandy soil, in a sunny place, at a depth of an inch. C. pulchellus is lovely on a sunny rockwork, or in a border, and is a delightful subject for the alpine house. *S. Arnott.*

COLOUR IN THE PLANT WORLD.

Nature is the supreme artist. She is never stingy in the use of colour, yet her effects are always harmonious and free from any suggestion of crudeness. In our flower gardens, in the summer, we can revel in the luxury of colour. When, later in the year, the flowers are dead, we can enjoy the beauty of autumn's golden tints and may pause to speculate awhile about the mystery of colour in the plant world. For colour is mysterious.

We are well aware, of course, of the vitally important part played in the economy of plants by that most important of all plant colouring matters, chlorophyll. It is by virtue of the chemical powers of this remarkable substance when stimulated by sunlight that plants are able to absorb carbon di-oxide from the atmosphere and convert it into sugar. But why is chlorophyll green ? The question is one which science has not yet succeeded in answering. It would seem, so far as the plant is concerned, that the colour is of no importance ; nevertheless, it is very important to mankind and, in a less degree, perhaps, to other animals ; an instance of that wonderful interlocking of phenomena — adaptation to circumstance, perhaps — which is everywhere to be observed in Nature.

Colours are classified by artists as cool and hot, and differ accordingly in their psychological effects. Green is essentially a cool, restful colour. Our eyes are most sensitive to green light, and can work without fatigue with a lower intensity of green light than that of any other colour. The benefit derived from a day spent in the country by the city worker is not due entirely to the fresh air and exercise. His mind has been rested by the constant sight of green fields and green trees. Undoubtedly, if the prevalent colour note of vegetation was red, our mentalities would be quite different from what they actually are.

Yet chlorophyll is so closely related chemically to the red haemoglobin of the blood, that the evolution of a red world, such as some very speculative minds have supposed the planet Mars to be, is not difficult to envisage.

It is gratifying to our vanity to suppose—if our imaginations are equal to the task—that the myriad hues which flowers display are flaunted for our delight. We may, however, be perfectly sure that they play some important part in the life of the plant ; and a plausible supposition is that their function is to attract the insects necessary for fertilisation, although, as a matter of fact, perfume would seem to be a more powerful factor in achieving this end, and the supposition does not seem applicable in all cases. In support of it, however, may be advanced the fact that, while in England, as in other low-lying countries, the majority of flowers are either white or yellow, when we travel to higher altitudes, where insect life is more scanty, the more brilliant and attractive reds and blues begin to become predominant. Many an alpine meadow in Switzerland looks blue from a distance owing to the abundance of Meadow Sage and other plants with blue flowers.

In recent years a great deal of attention has been paid to the question of the chemical composition of the colouring matters of flowers. These are mostly substances of very complex constitution. Some have been synthesised in the laboratory of the chemist ; but by how laborious a process compared with the ease with which plants make these same substances from the simple constituents of the air and soil !

The occurrence of albinism in plants is an interesting phenomenon. Not infrequently one finds a wild flower with apparently white blossoms which normally has coloured ones, although on pressing the albino, the colour sometimes develops as if it was always there, although hidden from sight. That some peculiarity in the soil is not the only, or even the chief, cause of albinism is evident from the fact that these abnormally white flowers are frequently found growing in juxtaposition to coloured ones of the same species. On the other hand, it is certain that the soil does have an effect on the colour of flowers. Blossoms of the blue-flowered variety of Hydrangea hortensis have been found to contain more than twice as much iron as those of the pink-flowered form, indicating the influence of a soil rich in iron. Cultivated plants of this species are often watered with iron salts to facilitate the development of the colour.

Many, indeed, have been the attempts by horticulturists to modify the colour of flowers by introducing various specific substances into the soil, and many wonderful results have been obtained. Black, at one time at any rate, was a colour especially sought after because of its rarity in Nature. It may, however, be doubted whether any perfectly black flowers have ever been produced, the nearest approximations to this colour being very dark shades of purple.

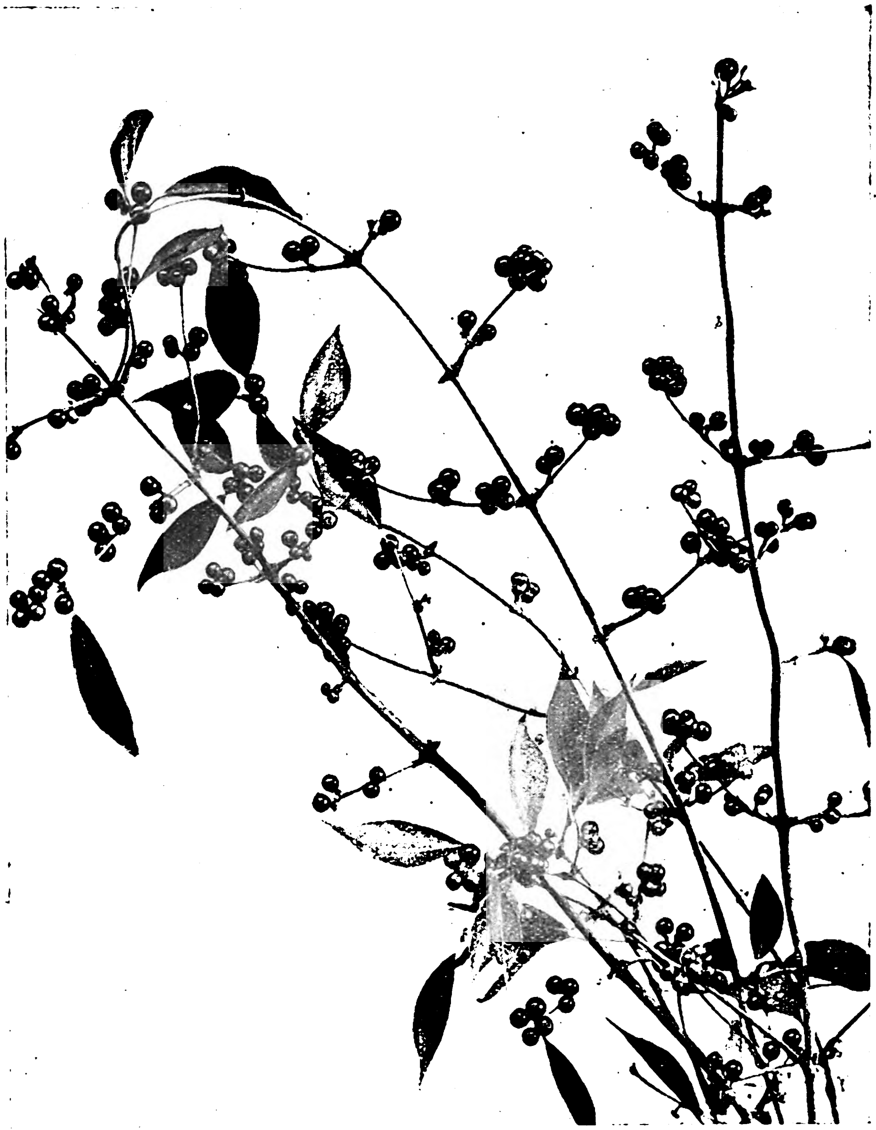

FIG. 175.—LONICERA SP.

R.H.S. Award of Merit, November 5, as Lonicera Hemsleyana. It is not that species, however, but probably L. Maackii var. podocarpa ; it has yet to be determined. Fruits red, semi-transparent. Shown by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Southampton.

(see p. 372)

The colouring matters present in flowers are, chemically of an extremely delicate nature. The colour soon fades ; and I suppose there is no curator of a natural history museum or possessor of a private herbarium who does not regret the fact that, although rapid drying often proves distinctly useful, no entirely satisfactory method of preserving plant-colours has been devised. Nevertheless, mankind has succeeded in obtaining from plants some of the most exquisite colouring matters—dyes and pigments—that are known, and which are still preferred, by those of good taste, to the myriad synthetic dyes and pigments now manufactured from coal tar.

Among useful colouring materials of plant origin, mention may be made of a number of woods, such as Logwood (Haematoxylon campechianum), Fustic (Chlorophora tinctoria), Young Fustic (Rhus Cotinus), Quercitron (Quercus velutina—syn. Q. tinctoria), etc., which have been extensively employed (and still are to some extent) for dyeing woollen and other textiles. Nor must we forget to mention Henna, the powdered leaves of Lawsonia alba, used especially for dyeing living hair.

Most important, however, of colouring matters derived from plants, of which many more might be mentioned, are Indigo and Madder. In the case of the plants producing these, on indication is given by any external sign of their tinctorial properties. The colouring matter is not *contained* within the plant, but is produced from one or other of its constituents by some simple chemical reaction. Indigo is prepared from certain species of Indigofera, plants belonging to the great family of Leguminosae. The leaves contain a peculiar glucoside or sugar compound, called indican, which undergoes fermentation and oxidation, with the production of indigo, when the powdered leaves are mixed with warm water and exposed to the air.

In the case of Madder (Rubia tinctorum), the dye, chiefly alizarin, is produced by fermentation of material contained in the root or when this is boiled with dilute acids or alkalies; and can be obtained in the form of an insoluble pigment, madder-lake, by chemical means.

The chemical composition of indigo and alizarin are both well-known, and these colouring matters are now synthetically manufactured on a large scale. However, the natural products appear to be superior to the artificial ones. The reason is probably the same as that which accounts for the fact that the finest synthetic imitation of a floral perfume falls short of the perfection of fragrance attained by the flower itself—the natural product contains traces of other substances, too small to be detected by analytical means which, nevertheless, modify, in one case the odour, in the other the colour. In the case of madder, it is well-known that other colouring matters are present besides alizarin.

Artists prefer natural madder-lakes to artificial ones on account of the beauty and delicacy of their colour. Speaking the other day to a director of a large British firm of pigment manufacturers, he told me that his firm supplied a certain railway company with natural madder-lake for painting railway trains, the company being prepared to pay the extra cost because the colour was considered to be superior to that of a similar synthetic alizarin-lake—a remarkable preference for a natural colouring matter in an industry where one imagined cost would have preference over aesthetic considerations.

Hotly pressed also by its synthetic rival, indigo still holds its own, reminding us of the truth of the remark with which I commenced these few notes on colour in the plant world, that Nature is the supreme artist. We may copy her, but her works, perhaps, we shall never excel. *H. S. Redgrove, B.Sc.*

NOTICE OF BOOK.

Spanish Gardens.

THIS is a charmingly written and beautifully illustrated book*, and altogether one of the most interesting and attractive productions of its kind we have seen.

The history of Spain is a fascinating tale, and perhaps no country in Europe has experienced such a succession of conquerors of diverse types, or been influenced more by them in turn, especially in regard to architecture. So far as the gardens of Spain are concerned, the Romans at first, and the Moors at the last, would appear more than any to have left their mark. The latter appeared as invaders from the south in the eighth century, and after acting successively as conquerors, rulers and subjects, they were finally expelled in the fifteenth. Thus, as one would expect, it was their dominion for so many years, over the southern parts especially, which had the deepest, most lasting, and to-day most evident influence on its gardens and architecture. In Andalusia the Moorish influence has continued almost unbroken until now.

But after having read and enjoyed this book, one feels that Spanish gardens as represented here, have but little concern with horticulture. In practically all the illustrations it is the work of the architect and artist in stone that dominates the scene. In some of the pictures not even a branch or a leaf is visible. One is led to wonder in the end if the beautifying of the earth with trees and flowers makes any appeal to the Spaniard, or even to the authoress of this book. It gives little evidence of it.

It is not necessary to labour that point or to revive in the least old and barren controversies. Gardening and architecture are two distinct, although allied arts. We can take delight in both, but this book ministers only to the delight in one.

Having written that much, we can unreservedly praise and recommend it. It is a deep pleasure to follow Mrs. Villiers-Stuart through that land of romance. Of romance, indeed, the very names are redolent—Cordova, Granada, Alhambra, Alcazar, Seville! No written story could imbue the reader more thoroughly than this with the atmosphere and genius of Spanish art in relation to the surroundings of its palaces and noble houses.

AUTUMN IN THE GARDEN.

MAY I venture to protest against the dull uniformity of Michaelmas Daisies and Dahlias in our autumn gardens? There really are other plants that may be employed by those who wish to keep a bright and flowery border.

Last winter was a severe one, as we all know, and Fuchsias were cut down to the ground in most places—but did that interfere with their blossoming last summer more profusely than ever? On the contrary, they were more beautiful than before. That charming sub-shrub, Ceratostigma Willmottianum suffered like the Fuchsias, yet, like them, it was a mass of brilliant blue flower heads in September and October, giving an impression of spring beauty more striking than the best of autumnal Gentians now so much in vogue.

The white Crinum Powellii was fuller of flower after having been cut down to the ground, and continued in bloom later than usual, proving its worth in the autumn garden, although it does not continue into October, but as it does not require any special care, it deserves a place both for foliage and flower. There are now good dwarf multiflora Roses, both pink and white flowers, that may be depended upon for autumnal flowering, and for those who prefer them, there are deeper shades. Rodhatte, for instance, will give a sequence of autumn flowers even although it may not be quite first-class in other ways.

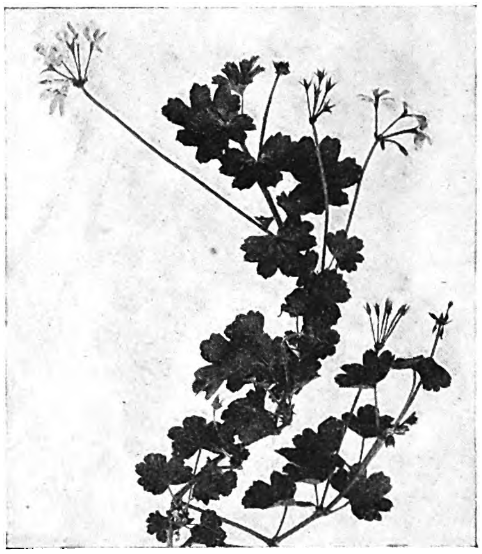

FIG. 176.—TALL GREEN-LEAVED SPORT FROM PELARGONIUM MME. SALLERON.

That best of Olearias, O. oleifolia, should not be forgotten as its pretty, white flowers, and foliage of spring-like green, give quite a summer air to the late autumn garden. It is so superior to O. Haastii that it needs to be better known, as it makes a green and spreading bush without any care or pruning.

I have in my mind's eye a big border planted with irregular, waving lines of Fuchsia Riccartonii and F. macrostemma var. gracilis. The latter should be cut down to the ground each year, but F. Riccartonii may be allowed to grow tall if the winters permit it, and it is in the background. Towards the front, that most indispensable of hardy Fuchsias, Madame Cornellisen, should show its bright flowers with white corollas. Its upright habit and fresh colouring are so cheerful that I am glad to think my old friend Miss Jekyll has saved it from oblivion. There are other good Fuchsias with white corollas, but of dwarfer habit, and all are worth a trial.

Silver-leaved Cinerarias and Centaureas may be used to group with the Ceratostigma or the Crinums; indeed, the energetic gardener will find plants to suit his taste.

There are now several good autumn-flowering Lilies that should be planted, but I write a line in praise of the good old Lilium auratum. But it should be mentioned that the Japanese cut off the roots of this Lily for convenience in packing, and it so happens that this species has perennial roots—not as other Lilies—so that newly imported bulbs should not be allowed to flower the first year, however strong they may be, for they only make fresh roots in autumn and in consequence the bulb dies of exhaustion, unless the flower buds are cut off in the first summer. Hence the idea that this bulb is not hardy. It is not frost, but lack of roots, that kills this lovely Lily, and it enjoys the shelter of the Fuchsias as well as the Azaleas with which it is commonly associated. *Edward H. Woodall, La Selva, Brancolar, Nice.*

NOTES FROM KEW.

OFTEN one of the greatest pleasures of a garden is the uncertainty of what may happen from week to week, or even from day to day. Writing in mid-October, or even later, one would have described the autumn tints as of moderate beauty, the colouring, with a few exceptions, below the average, due, one would suggest, to the long spell of dry weather, and the early falling of some of the leaves.

In less than a fortnight a marvellous change came over the landscape. A considerable amount of rain fell, and an indifferent beginning was changed in a few days to brilliant colouring wherever the eye wandered. Especially fine are the Liquidambars, the Common Beech, the Barberries, the Azaleas, the Pyruses and some of the Elms.

The American Sumach, Rhus cotinoides, is one of the most beautiful and consistent of all autumn colouring trees or shrubs, and always makes a gorgeous display of scarlet, orange-red and golden-yellow. It is worth noting that most brightly-coloured leaves are on bushes planted in rather poor ground. Rhus trichocarpa, a native of Japan, is another Sumach of outstanding merit in autumn; the pinnate leaves assume brilliant shades of deep orange-scarlet and golden-yellow.

The June Berry, Amelanchier canadensis, is a useful specimen lawn tree of moderate dimentions, twenty to thirty feet in height. A profusion of small, white flowers open during April just in advance of the leaves, and in autumn the trees are pictures of striking beauty when the leaves are glowing red.

Pyrus Tschonoskii is a Japanese species of very attractive appearance at the present time (November 1) as it is of pyramidal habit, and the leaves are rich orange and scarlet. Crataegus pinnatifida var. major has pleasing autumnal tints of bronzy-orange, while the tree is very heavily laden with clusters of large, dark red fruits. C. prunifolia is of outstanding merit, forming round-headed trees as wide as high, and at present a glowing mass of orange and crimson, conspicuous from a long distance. The Washington Thorn, C. cordata, is one of the most useful and distinct Thorns in flower and fruit; it is also one of the latest to bloom, the flowers opening in early July, to be followed by small, orange-scarlet fruits produced in profusion. The yellow-fruited Yew, Taxus baccata var. fructu-luteo, is more attractive in fruit than the ordinary variety, as the colour forms a greater contrast to the dark green foliage. It is of more spreading habit than the ordinary form of the Common Yew.

Four species of Koelreuteria are in cultivation at Kew, all natives of the east; three from China and the fourth from Formosa. Two, K. bipinnata and K. formosana, require the protection of a greenhouse at Kew, and the other two, K. apiculata and K. paniculata, are hardy, deciduous trees or large shrubs. K. paniculata was first introduced to British gardens in 1763. Although not much grown it is a very good subject for town gardens, thriving in poor soils and the by-no-means pure air of Battersea Park, for example. At Kew the older introduction is surpassed as a decorative subject both in flower and fruit by K. apiculata, first discovered by Mr. E. H. Wilson in western Szechuan in 1904. Mr. Wilson describes it as a large bush, or small, deciduous tree, ten feet to forty feet in height, with a trunk up to three feet in girth. The attractive, pinnate, often doubly-pinnate leaves are from about eight inches to eighteen inches long and half as wide. The yellow flowers, half-an-inch long, are borne freely in terminal panicles during July and early August at the ends of the growths of the current year. The flowers are followed by inflated, three-valved capsules about two inches long and one inch broad. These turn bronzy-red in autumn, and are very ornamental during September and October. Each capsule contains normally six seeds, these providing a ready means of increase, although root-cuttings also may be used should a plant not have reached the flowering stage. *A. Osborn.*

PLANT VARIATIONS.

(*Continued from p.* 368.)

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

Pelargonium.

Pelargoniums of the scented-leaved section, or Cape Pelargoniums of the old florists:—

P. Rollissons' Unique, a reputed hybrid between P. capitatum and some garden variety sent out by Messrs. Rollissons, of Tooting, near London, has given rise to several sports, sometimes by buds, but whether any of them came from root-cuttings has not, to my knowledge, been recorded.

At Merton, this typical purple form gives rise to a pale or lilac-coloured form of flower. We have not yet succeeded in raising either of these forms from roots. (See *Gard. Chron.* Dec. 22, 1923, p. 364, for a full account of this plant).

The variegated form of P. graveolens, the Oak-leaved Pelargonium, known as Lady mouth, grows easily from root-cuttings, but the resulting plants are green. P. Clorinda is a garden hybrid with large, rose-coloured flowers. This plant comes quite true from root-cuttings. It sometimes produces a paler or lilac-coloured flower sport called Joan. This was propagated by means of stem cuttings. In course of time, root-cuttings of the latter were made, and a large number of plants raised, all of which reverted to Clorinda. Clorinda, in common with nearly all sporting plants, frequently has some of the petals or half of a petal of a different colour to the rest.

Pelargonium Mangles's Variegated, or Mangles's Silver Leaf, and also known as Pelargonium Manglesii, is a variety of free, spreading and slender habit, having leaves broad, flat, lobed, and irregularly white edged, and flowers small, pale pink (Fig. 177). In the *Cottage Gardener,* Vol. 13, 1855, p. 499, will be found the following reference: "A natural sport from a thin-leaved Horseshoe, pink-flowered species, which will not breed with any other species," and in Vol. 16, 1856, p. 45, is a note by Donald Beaton: "That beautiful sport called Mangles's Variegated appeared little more than twenty years since in the garden of Captain Mangles, at Sunning Hill; when well done, it is the best of all our variegated Geraniums yet." At Merton, the plant occasionally produces green-leaved sports, both spontaneously and from root-cuttings. These sports have flowers identical with those of the parental variegated form.

At Merton, another form with the variegation, less distinct, is grown under the title of P. Menziesii, a name, however, which cannot be traced in catalogues or books. This plant also produces green-leaved sports, spontaneously, and from root-cuttings, identical with those produced by Mangles's Variegated.

Pelargonium Madame Salleron, also known as Madame Salleroi, Madame Salleroy, Little Trot, etc., is of very compact, dwarf habit. The leaves are small and thin, with white margins. The internodes do not lengthen as in Mangles's Variegated, and in this, its normal condition, it has never been recorded as having produced flowers.

Madame Salleron will sometimes produce shoots of the original parental form, Mangles's Variegated, in which case it produces flowers. Root-cuttings, too, will sometimes come quite dwarf, with green leaves, in which condition it does not flower. It would appear that the dwarf forms, both variegated and green, in which the internodes have not developed, possess some inhibiting factor which prevents the formation of flowers (Fig. 178). When, however, it develops the tall, green-leaved sport, and when grown from root-cuttings, the internodes lengthen, and the plants attain a height of fully three feet and produce small, pink flowers (Fig. 176), similar to Mangles's Variegated (*Gard. Chron.*, 1923, ii, p. 364). A specimen of the green-leaved form submitted to Kew for identification was declared to be a good match of Pelargonium alchemilloides, a common South African species. According to H. Dauthenay (*Les Geraniums*, p. 164, published in Paris, 1897), this variety originated in 1877 in the garden of Madame Salleron, Melun, as a sport from a bed of Mangles's Variegated.

It is interesting to note that Mangles's Variegated, Menziesii, and Madame Salleron, not only produce green-leaved sports, but also white-leaved sports, which, of course, quickly die. *A. Hosking, Garden Superintendent, John Innes Horticultural Institute, Merton, Surrey.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

LILIUM CANDIDUM VAR. PEREGRINUM.

FROM time to time and for no very obvious reason, interest in old and more or less forgotten plants flares up, with the result that they are temporarily rescued from comparative obscurity and find a multitude of new friends. Judging by the number of letters received from correspondents, something of the kind must have happened last summer in the case of the variety of L. candidum called peregrinum, which has never had the vogue enjoyed by the type and has always remained more or less in the background. Whether that has been due to some want of the qualities of the type or to one of the unassignable reasons which often seem to determine the popularity of a flower, is, perhaps, a matter of opinion, but those amateurs who grow the plant more for its interest than its intrinsic beauty, are probably not far wrong.

Of the origin of the plant, as distinct from its first appearance in cultivation, we know nothing, but the main peculiarities which distinguish it — the nodding habit of the bell-shaped "starry" flowers, with petals narrowed at the base and leaves both fewer and narrower than those of the type—have induced more than one investigator of the past to regard the plant as a good species. Until someone proves by experiment that seeds of L. candidum throw plants of the type, that is, with semi-erect flowers, having broad petals and stems with broad leaves, as well as plants with nodding narrow-petalled flowers and narrow stem leaves, the varietal standing of peregrinum must always remain in doubt. The weight of evidence, however, in favour of that standing, is reasonably conclusive.

A black stem is commonly held to be a characteristic of the variety peregrinum, but the writer has been unable to find the origin of the belief, or any justification for it, except a reference to it by Solms-Laubach in circumstances referred to below. Clusius, who first described the plant (1583) as Sultan Zambach, made no mention of the character, nor did Miller (1768), who gave it specific rank as L. peregrinum; and we are entitled to assume that each would have noted the black stem had he thought anything of it. On the other hand, both authors quote the pendulous flowers as a character, and it is undoubtedly the important one.

So-called "black"-stemmed forms of Lilies which normally have green stems, are so common as to excite comment, and they may often be found in colonies of L. candidum. They are of spontaneous origin, as anyone interested may see for himself, by sowing a capsule of seeds of L. longiflorum var. formosanum, for example, for both purple and green stems will be found among the seedlings. It is the same with L. Martagon var. album, L. Henryi and L. superbum, among others, and even with L. giganteum. Sometimes, where white-flowered Lilies are concerned, the purple pigmentation of the stem coincides with a similar colouring of the keels of the petals, as in L. longiflorum, or in a deepening of the purple markings of the flower, as in L. giganteum; but there does not seem to be any definite rule about it.

In the writer's experience the peculiarity is only perpetuated to a comparatively minor extent by seminal propagation, and to make sure of a perpetuation of it, it is necessary to propagate a black-stemmed variety of any Lily by one of the many familiar vegetative processes.

So far, therefore, as the actual origin of the black-stemmed varieties of the Madonna Lily is concerned, we may be content to regard it as spontaneous. Indeed, it is not impossible that the original form of L. candidum may have had a black stem, and that what is called the type may have derived from it!

Of the history of the variety peregrinum in gardens, much more is known than can be written of many plants which, like this Lily, were introduced to cultivation about 350 years ago. Towards the end of the last century the variety came under the notice of Solms-Laubach and that erudite amateur probed the history and synonymity of it with customary thoroughness.[*] His citation of authorities was voluminous, but the wisdom of his recognition of the black stem as a specific character is open to doubt.

Centuries, however, before the Duke of Solms-Laubach's time, this form of L. candidum had come under the notice of Clusius,[†] and it was through his agency that it was first brought into cultivation in western Europe. At this time the precise date is immaterial, but it must obviously have been during the thirteen years ending in 1587, which Clusius spent in Vienna, and must have been prior to 1581, as Lobelius published a woodcut of the Lily in that year.[‡] The plant came to Clusius from Constantinople as Sultan Zambaq—literally, the King's Lily, from the Persian *Zanbe*—which was corrupted into Zambak and Zambach, a name that persisted in dealers' catalogues until modern times. Accompanying the bulbs was a copy of a catalogue (in Italian) in which the Lily was described as *Fa grandi fiori bianchi* and *a odore de giglio*.[§]

Thinking that the Lily was a new species of L. Martagon, Clusius sent some bulbs of it to friends in Belgium as L. Martagon constantinopolitanum—a name which clung to the plant for long afterwards—and it was not until the Lily flowered that he realised that, in vulgar parlance, he had "been sold a pup." Clusius's chagrin at the discovery will be shared by the many gardeners who have suffered much the same kind of disappointment in the case of other plants, and it may account for the scrappiness of his description of the Lily. Clusius did not even think it necessary to refer to the nodding habit of the flowers, although the character is shown clearly enough in his figure. It is typical of the confusion of which this Lily has been the subject, that this old figure of Clusius's is one of the few in which the nodding habit is portrayed.

We have seen that during his sojourn in Vienna (1573-1587), Clusius sent bulbs of the Lily, Sultan Zambach, to Belgium, and the plant was not long in finding its way to Holland, whence, as has been the case with so many plants, it reached this country. Here it seems first to have come under the notice of Miller,[‖] who, notwithstanding the prior publication of the Lily by Clusius as Sultan Zambach, made it a good species as L. peregrinum, literally, the foreign Lily. K. Bauhin[*] had referred to it as such 145 years before, and possibly that influenced Miller in his choice of a name. Gerarde had it in the list of plants (*Herball*) he cultivated in 1596, but under the name given to it by Clusius, and Linnaeus referred it back to L. candidum. Modern authorities have not been disposed to regard the Lily as worthy of specific rank, for Baker[†] rated it as a variety of L. candidum, and Elwes[‡] viewed it in the same light.

There is no figure of the variety peregrinum in Redouté's *Les Liliacées*, but in the text, De Candolle, after quoting the descriptions and figures of Clusius, Lobelius and de Bry (who, however, each copied Clusius), so well as Miller, refused to believe "that after a single inspection of the figures cited, one could retain a doubt as to the distinction between the two species (L. candidum and L. peregrinum), especially when one considers the positive assertion of Miller."

Miller, who apparently cultivated his L. peregrinum, which he called the white foreign Lily with pendant flowers, relied for his specific characters on the nodding habit of the flowers, which, in L. candidum, are semi-erect; their smaller size and thin petals narrowed at the base, which produce a "starry" effect; and the shorter stem with fewer and narrower leaves. It did not seem to have occurred to Miller to satisfy himself by raising the Lily from seeds, that all the characters on which he relied were constant, but short of that, the only one which would carry any weight now is the nodding habit of the flowers.

Solms-Laubach went far more minutely into the differences between the Lilies than Miller had done, and growing the two side by side, was able to make a comparative analysis, as it were, of the salient points of each. He found the major differences with which students are familiar—the almost pendulous poise of the flowers, the greater length of the leaves, and the comparative absence of the twist in them. He referred, too, to the violet-brown of the stem and leaves.

He found, also, in the flowers, a host of minor differences of the kind any observer who is on the look-out for them can find in such circumstances, and observed many points in which the fruits of the two Lilies were dissimilar; and in the end, after a reasoned consideration of the pros. and cons., reached the conclusion that the difference between L. Sultan Zambach and L. candidum were of a comparatively unimportant nature.

As Solms-Lambach observed, this variety of L. candidum has a considerable history, which, incidentally, is enriched by a wealth of references to authorities rarely found in similar circumstances. Anyone specially interested in the subject will find an ample citation of references to Clusius's Lily in Rédoutés *Liliacées*, wherein, however, the Lily is not figured. This is the more to be regretted as that master never left any doubt in the enquirer's mind as to the identity of a plant he figured.

The Lily was figured in the original description of Clusius and in Bauhin's *Pinax*, and the illustration in the latter work was made use of by several subsequent writers.

In his *Pharmaceutical Plants*,[§] the German author, Hayne, had an illustration of a slender young plant, with the observation that both kinds of the white Lily had been established in the garden of C. Bouché, art and commercial nurseryman, in Berlin, and after growing in a long row for years, showed the stability of both forms. Unfortunately, however, this figure has the flowers, at right angles to the stem and not in a nodding position! That did not prevent Solms-Laubach from regarding it as the best modern illustration of L. peregrinum, a view which shakes one's faith in his judgment, as it seems merely to represent a typical form of the thin-petalled, starry-flowered variety of L. candidum.

In this country L. candidum var. peregrinum has had its ups and downs, and like many old plants which are never common, but which, equally, never seem to die out, there is sometimes attached to it a legendary importance to which its merits hardly entitle it. For all that it persists in some places, it does not seem to have all the qualities of endurance which make L. candidum the common plant it is; but no one who wishes to grow it need anticipate any difficulties on that score.

The name speciosum has been attached to a variety of L. candidum which has a "black" stem and narrow, pointed, snow-white petals. I have been unable to find any formal publication of the name, which, like so many plant names, seems to have originated in a Continental nurseryman's catalogue, possibly that of Van Houtte, of Ghent. The variety of L. Martagon var. album called "superbum" is another instance of the same practice. The precise differences between the varieties speciosum and peregrinum are unknown to the writer, but they seem to turn on the way the flower is carried on the pedicel. It will not be a matter for surprise if the nodding habit of the bloom is the determining character in Clusius's Lily. *A. Grove.*

HYBRID BARBERRIES AT WISLEY.

Just thirteen years have elapsed since, in November, 1916, Berberis rubrostilla was shown at a meeting of the Royal Horticultural Society and awarded the much coveted First Class Certificate. Since the début of this hybrid—still the most beautiful-fruited of all the Barberries—many thousands of these red-fruited hybrids have been raised at Wisley where, every autumn, they constitute probably the most attractive feature of the gardens, and every year thousands of packets of seeds collected from them are sent out to the Fellows of the Society at the annual "distribution."

The best of the early hybrids were named and shown at the meetings of the R.H.S., but good ones soon became so numerous that it was considered impolitic to continue the naming of them and they are now referred to as the race of Wisley hybrid Barberries.

As autumn-fruiting subjects they are invaluable, for they present a wide range of form and colouring in their fruits, which, provided the bushes are carefully tended, are produced in prodigious quantities; they are also very variable in habit, although this variability is confined, to a greater or lesser degree, to the various classes, defined according to parentage.

As stated, B. rubrostilla was the first to receive recognition. It is a hybrid, and its parentage is unknown as it appeared by chance among a batch of seedlings raised at Wisley. When shown, it was stated that attempts would be made to ascertain the parentage by raising seedlings from it; this latter work has been done, but the doubt as to the parentage still exists; for the seedlings have given rise to an extraordinary range of varieties, many of which are extremely fine and almost equal B. rubrostilla in beauty.

B. rubrostilla (*Gard. Chron.*, Nov. 11, 1916, Fig. 93) is a shrub of graceful habit, its erect growths attaining a height, when grown in bush form, of about four feet, and from them spring the gracefully arching lateral growths which bear the fruits. These are fully half-an-inch in length, large and striking, firm and fleshy; from green they change to almost white, and then gradually take on a cerise tone, until, by the end of October, they are a wonderful translucent, light sealing-wax red. The fruits are borne in clusters of two to five or six, on slender stems arising from the centres of the clusters of light green leaves disposed along the lateral growths. When trained against wire supports and grown as an ornamental hedge, for which purpose B. rubrostilla, together with the tall-growing B. polyantha hybrids, is admirably adapted, it will attain a height of five to six feet.

In a group of varieties derived from B. rubrostilla are to be found the best of the bush-forming hybrids, with a range in height of between three feet and four-and-a-half feet, and very suitable for planting in shrub borders, either singly or in groups. Among named sorts in this group are Autumn Beauty, Firefly and Sparkler, three of the most striking varieties produced.

B. Autumn Beauty (*Gard. Chron.* Oct. 6, 1923, Fig. 77) ranks next to B. rubrostilla and forms a handsome bush up to about three-and-a-half feet high, of more or less erect habit, the lateral growths being closely set with clusters of up to seven, sometimes more, brilliant, coral-red fruits, conical in shape, and three-eighths-of-an-inch long. This magnificent hybrid was shown at the R.H.S. meeting on October 2, 1923, when it received an Award of Merit. B. Firefly has brilliantly-coloured fruits, but does not equal B. Autumn Beauty as an all-round garden shrub, being somewhat less vigorous and not so regular in fruiting.

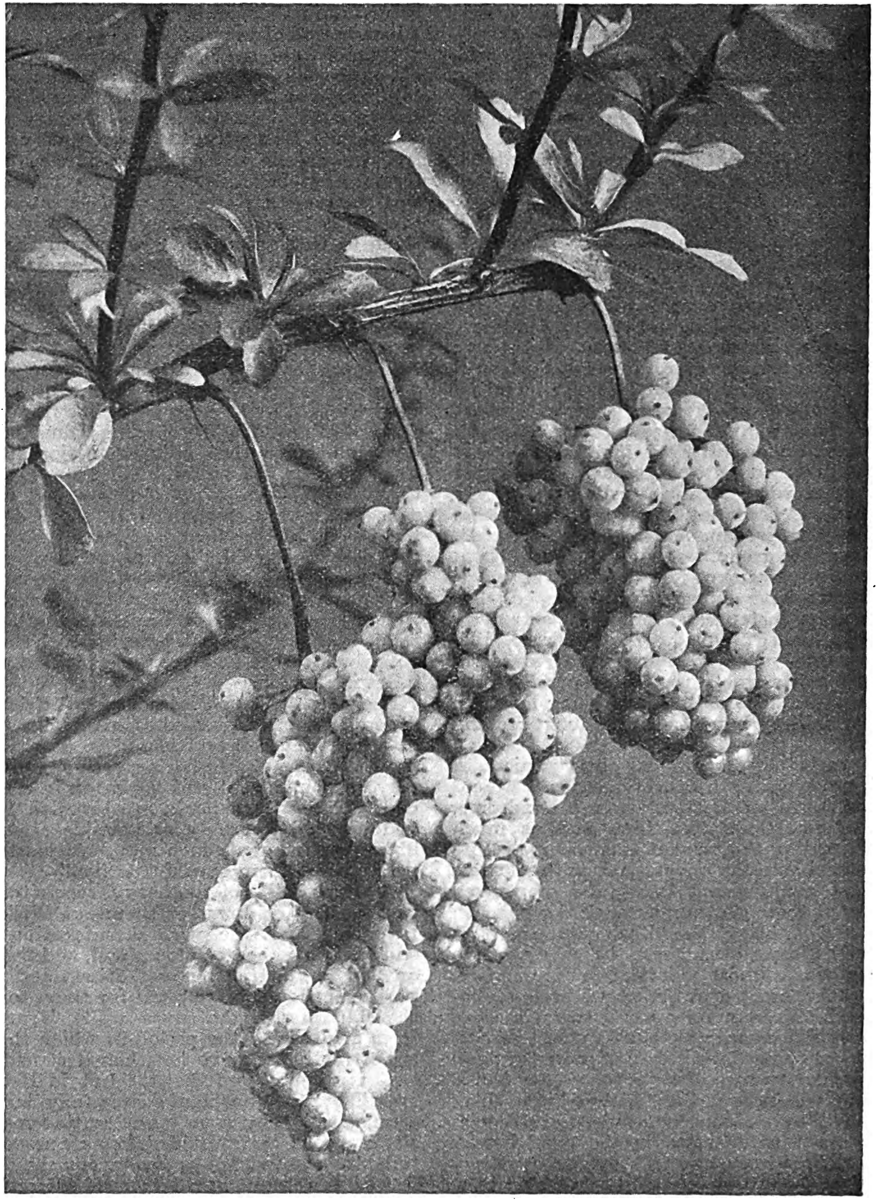

FIG. 179.—A HYBRID BARBERRY AT WISLEY.

B. Sparkler is well-named, and it deserved the Award of Merit bestowed upon it on November 1, 1921, for it is a shrub of graceful habit, its pendulous lateral and terminal growths being set with trusses of up to about ten inverted Pear-shaped, glowing cerise-red fruits, which before reaching maturity are covered with a film of "bloom." This hybrid is free-fruiting, the whole bush becoming a sparking column in the autumn sunshine. The hybrids described above are typical of the B. rubrostilla group—free-fruiting, free-growing if carefully tended, and of good habit, and all producing fruits of good substance and vivid colouring.

B. Wilsonae, and the natural hybrid B. ferax, have given rise at Wisley to a distinct group of hybrids, but so far as decorativeness is concerned they do not, with few exceptions, compare favourably with the preceding group. Nearly all of them have the habit of growth of B. Wilsonae, forming low, dense, spreading bushes, and with greyish foliage, so that the fruits, produced often with prodigal freedom and varying somewhat in size and colouring, lose much of their effectiveness by being hidden from view owing to the denseness of the growths. For table decoration, however, the fruiting sprays of this group are very effective, the fruits, in shades of coral-red, looking very attractive under artificial light. This, however, is no recommendation for their general planting, as the majority of the hybrid Barberries are very suitable for this purpose—until the fruits commence to drop.

B. Coral is a named member of the B. Wilsonae group, of low-growing habit and with very grey undersides to its foliage. It is free-fruiting, the lateral growths, which are formed along practically the whole length of the main growths, being packed closely with small fruits in a good shade of coral-pink, the whole making wonderful sprays of berries. B. Tom Thumb, raised by S. Morris, Esq., of Monbretia fame, and awarded an Award of Merit when shown before the R.H.S. on October 16, 1923, is stated to be a hybrid between B. Wilsonae and B. aggregata. It is very suitable for growing on the rock garden or bank owing to its dwarf stature and spreading habit, its fruits being like those of B. Wilsonae.

With B. subcaulialata (*Gard. Chron.*, Jan. 16, 1926, Fig. 19) as the seed parent, another distinct range of hybrids has been obtained, the majority of which show affinity to the seed parent. They are of low, spreading growth, and many of them fruit so heavily upon reaching maturity that, unless checked in this respect, they cripple themselves. B. Comet (*Gard. Chron.* Feb. 2, 1924, Supp. Plate) is an example of this. When given an Award of Merit, on October 30, 1923, its long, arching growths were so packed with clusters of small, cerise berries from base to tip that it was difficult to see any of the stem between them, and this prolificness was continued for a year or two. This year, the two stock plants are barren, nor have they made much growth. B. Comet is certainly the most striking of the B. subcaulialata class, many members of which portray the same habit of fruiting to excess, thereby rendering themselves stiff and ungainly in appearance and not to be commended.

Next to the B. rubrostilla group, those with B. brevipaniculata blood are the best of the bush type, and these gradually merge into the B. polyantha section. The purplish "bloom" of the fruits of B. brevipaniculata is apparent in most of the hybrids from it, and it is, perhaps, a pity that a few more of them have not been named. The fruits of the members of this group are small, rounded, and produced in large, dense clusters which may consist of seventy or more berries hanging gracefully from the lateral or main growths, as in the hybrid illustrated (Fig. 179), which was shown recently at Vincent Square. This hybrid forms a compact bush about three-and-a-half feet high, with stout growths furnished with laterals in the upper portion, and when fruiting well is extremely handsome. It shows affinity to B. polyantha.

B. Fireflame is a named member of the B. brevipaniculata group, but since this was shown and given an Award of Merit, on November 1, 1921, others have appeared and are equally, and in some instances, even more attractive than this named hybrid. B. Fireflame, like all the members of this group, is extremely free-fruiting, its small, round, deep red fruits, covered with "bloom" at first, being borne in compact, axillary bunches on the long, arching growths.

One especially good B. brevipaniculata hybrid, growing in the collection near the pond in Seven Acres, at Wisley, forms a handsome, rounded bush, three feet high and as much through, and at the present time nearly all its short lateral growths are packed with clusters of typical small, round fruits, the orange-red colouring of these showing through the purplish bloom and lighting the bush up so that it is easily discernible among the many. Two other hybrids, almost identical in appearance, have slender, erect growths about three-and-a-half feet high, forming graceful, open bushes, and carrying numerous clusters of berries, the bunches being three inches or more long and containing an average of sixty to seventy fruits. In some of the hybrids the "bloom" is so thick that the fruits are distinctly purple, and although these are not so effective in the open border as the brighter-fruited sorts, they are an attractive variation and very beautiful in artificial light.

Another very important section of these hybrid Barberries is the B. polyantha group, the members of which are very attractive in the bush form, when they attain a height of five to six feet, but are most effective when trained against supports to form an ornamental hedge. At Wisley, such a hedge is to be found on the margin of the formal Azalea garden. The main growths are secured to cross-wires to a height of six feet or so, and the terminal and lateral shoots are left free to droop gracefully over, and when these are all heavily fruited the hedge presents a magnificent spectacle of brilliant colouring, in vivid shades of orange and vermilion. The fruits are small and round, and packed closely along the laterals in dense clusters of twenty to forty, often many more, so that the growths are weighed down by the fruits. When grown as a bush the gracefulness of these hybrids is lost, unless stout stakes are provided to support the main stems.

Up to the present, the Wisley hybrids have been produced on a large scale, with the result that there are now several thousands of them, many extremely beautiful and worth perpetuating, but, of course, a large number are worthless, and it is now time that the collection was thoroughly overhauled, and all the inferior hybrids scrapped, as these detract from the charm of the finest forms. When this has been done, selective hybridisation may result in even greater achievements, for there appears no end to the variations of which these red-fruited Barberries are capable, while there are several untried species which might also be introduced as parents.

The red-fruited Berberis hybrids are not exacting in their requirements, nor is it difficult to maintain them in a cropping condition over a long period of years.

Raised from seeds, they come into bearing about the third or fourth year; cuttings of good forms are not difficult to root, while layering of the growths of established plants may also be practised. Naturally, the hybrids do not come true from seeds, but usually a number of good forms may be secured by this method. If the berries are stored in sand—stratified—for the winter, the seeds may be rubbed out of them in the spring and sown, with the sand, in a seed-bed out-of-doors. Germination is usually rapid and the seedlings soon develop extensive root-systems, far out of proportion to the top growth, which is limited in the first year. If the seeds were sown thinly, the seedlings may be left undisturbed for the first year and given every encouragement to make early growth, by keeping them free from weeds, and watering and lightly shading them during the hot summer months; light protection may also be afforded in the winter. The following spring they may be transplanted into a bed of good soil, when top growth will soon develop; by the end of the third year good bushy plants will have formed. An alternative method is to sow the seed in five- or six-inch pots and prick the seedlings out into boxes, from which they may be transplanted into a bed in the open, or into small pots, in which they may be grown for the first year and planted out the following spring.

Short, well-ripened lateral growths should be selected as cuttings and these, if inserted in pots of sandy soil and placed in a cold frame, should root by the following spring, when they may be planted out and grown on in a nursery bed. The cuttings should be taken with "heels" and inserted so firmly as possible around the inner margins of six-inch pots. At least eighty per cent. of them should "strike."

A loamy soil, not too heavy, seems to be the best rooting medium for them—at Wisley, the B. polyantha hedge, with B. rubrostilla at one end of it, is on heavy, clayey soil, and the plants are in a flourishing condition—and sunny positions should be selected for them to ensure the colouring of the fruits while, if protected from cold winds, the period in which the fruits are attractive may be lengthened considerably.

It is often stated that the hybrid Barberries are difficult to transplant successfully, but this is erroneous. They form large, matted masses of slender roots, and provided they are moved carefully and planted firmly, specimens six or seven years old, or more, may be moved successfully.

Pruning is the most important operation in their culture, and the most unpleasant owing to the needle-spines with which their growths are amply furnished. Stout leather gloves should be worn, as the spines are not easy to remove from the hands once they have penetrated, and are likely to prove exceedingly painful.

The fruits are produced on the growths of the preceding season, therefore it is necessary to maintain a good succession of annual growths. If, early in the season, the young growths are thinned, those left will develop into good fruiting sprays, while the growths which have borne fruits may be cut back to the base so soon as the berries have ceased to be attractive, which will depend upon the severity of the early winter. By this method a good balance of growth may be maintained and the bushes kept in a vigorous condition for many years. If left unpruned, they may crop prolifically for a few years but will soon wear themselves out.

The pruning of the B. polyantha hybrids when grown as ornamental hedge plants and trained against supports, is slightly different to the method adopted for bushes. Main growths are laid in to form the frame-work, and the fruited laterals are spurred back to within an inch or so of the parent stems, their places being taken by the growths of the current season. If this is attended to regularly, the spurring back of the fruited—previous season's —growths should result in the annual production of vigorous lateral growths.

Finally, it is worthy of note that, although grown primarily for their fruits, the Wisley hybrid Barberries are by no means unattractive when in blossom, while in the autumn their foliage often assumes rich colouring, thereby increasing the already brilliant effect. *F.*

THE GENUS PRIMULA.

(*Continued from p.* 369.)

SOULIEI (Franch.). Souliei's P.
(Souliei).

A DWARF, deciduous, non-mealy, perennial species with a tiny rosette of rather thin, oval, blunt leaves from half-an-inch to one inch long, truncate or obscurely heart-shaped at the base, tapering to comparatively long, slender, narrowly winged stalks; margins furnished with rounded, regular teeth; both surfaces covered with short, stiff hairs. Flower stems numerous, one inch to four inches tall, bearing one or many, terminal, purple-violet blossoms on long, slender stalks. Corolla very broadly funnel-shaped, about three-quarters-of-an-inch across, with short, broad, bilobed segments; tube cylindrical, longer than the calyx.

Grows in cool, rocky places, on the mountains near Tatsienlu, in Szechuan, central China.

Culture: Grow it in peat and fibrous loam, in a cool, half-shady spot, with protection from damp in winter.

SPATHULIFOLIA (Craib). Spatula-leaved P.
(Minutissimae).

This pretty little species was formerly considered but a variety of P. minutissima, Jacq.. It is a dwarf, densely-foliate perennial with creeping stolons; the tufts of deep green leaves have spathulate-oval blades, half-an-inch to one inch in length, with rounded tips and margins, edged with coarse, rounded teeth; usually smooth above and coated with pale-coloured meal beneath. Flower stem very short, immersed in the foliage, bearing one or two pale purple, stalkless blossoms. Corolla nearly three-quarters-of-an-inch across, with broadly heart-shaped, deeply cleft lobes; tube cylindrical below, dilated upwards, about five-eighths-of-an-inch long. Flowers in June and July.

Grows in rock soil among dwarf herbage, in the Sikkim Himalayas, at about 13,000 feet above sea level.

Culture: As for P. minutissima.

SPECTABILIS (Tratt.). Showy P.
(Auricula-Arthritica).

A very delightful European perennial species with a rosette or tuft of broadly diamond-shaped or oblong, pointed leaves, one to three-and-a-half inches long; margins quite entire, with a broad, cartilaginous edge; upper surface bright shining green, both surfaces dotted with minute, transparent glands emitting a somewhat viscid secretion. Flower stem two to six inches tall, bearing an umbel of one to seven rose or rosy-mauve blossoms. Corolla broadly funnel-shaped, three-quarters-of-an-inch to one-and-a-quarter inch across, with broadly heart-shaped, notched lobes; tube cylindrical below, dilated upwards, longer than the calyx. Flowers in July. Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Introduced in 1879.

Grows in large masses in alpine pastures in open, sunny places, usually on limestone formations, in the Alps of Judicaria and Verona at 1,500 to 7,000 feet above sea-level.

Culture: Rich, fibrous, calcareous loam, in an open situation are the conditions which suit this deep-rooting and vigorous species best
A. W. Darnell.

(*To be continued*).

EARLY-FLOWERING CHRYSANTHEMUMS.

During the past two years (1928 and 1929), a comprehensive trial of early-flowering outdoor Chrysanthemums has taken place under the auspices of the National Chrysanthemum Society, in the nursery of Mr. W. Hatch, Cookham, near Maidenhead. Mr. Hatch has taken the keenest interest in the trials, and it is largely due to his desire to help the National Chrysanthemum Society and, incidentally, help growers, that he offered late in 1927, to set aside an area in his nursery for the purpose of making an exhaustive trial of these popular flowers.

Last year's initial effort was not a success, as the plants sent in for trial by various members of the trade and other growers were propagated at different periods, and for this reason a proper comparison between the different varieties could not be made.

The sub-committee responsible for the trial was selected from the Society's Floral Committee, and consisted of the Chairman, Mr. D. B. Crane, and Messrs. P. A. Cragg, D. Ingamells, Thomas Stevenson and Charles Davis. Although last year's effort was somewhat disappointing, the Committee was able to eliminate a number of varieties that were synonymous or too-much-alike, and in consequence were able to restrict the number of sorts under its control. A matter of supreme importance in a trial of this character was that the propagation of plants for the current year was carried out at one and the same time; as a matter of fact, the first batch of cuttings was put in in late February and the second batch in early March.

In order to improve the condition of the soil in the area allocated to this trial, a good dressing of farmyard manure was applied, and the quarters thoroughly trenched. The surface soil was left rough for some time, and at the time of planting a sprinkling of Clay's fertiliser was applied. Planting out in the flowering quarters took place during the third week in May, and the more satisfactory condition of the plants this year is largely due to the fairly generous treatment the plants received.

There were no fewer than 290 stocks planted and three plants of each variety; one plant of each variety was disbudded and the remaining two left to grow in natural fashion.

The trial was inspected by the Sub-Committee on two occasions while the plants were in flower, viz., September 24 and October 8. A goodly proportion of plants were in flower on the occasion of the earlier visit, and these were carefully inspected and points awarded to varieties of sufficient merit. The interval of a fortnight between the two visits enabled the Sub-Committee to see many varieties that were not ready for inspection on the first visit, but very many were too late in coming into flower, and for this reason could not be regarded as early-flowering.

Points were awarded to varieties of outstanding merit, three points being regarded as the maximum for the better varieties and two points to others less meritorious in their general character. No lower award was made.

Many old and once popular varieties failed to gain recognition, being easily outclassed by those of recent introduction. Here and there were instances in which some of the older sorts were doing well and holding their own against the newcomers; their constitution, habit, freedom of flowering, and the character of the flowers leaving little to be desired. The trial has proved most conclusively that we are no longer dependent on continental raisers for new early-flowering Chrysanthemums, as quite a large proportion of varieties in the trial, originated in the gardens of British raisers, and these in most instances were distinctly superior in every way to those of continental origin.

A noteworthy fact was the large number of synonymous sorts and those too-much-alike to others of proved merit, and to this aspect of the trial the Sub-Committee gave especial attention.

In adjudicating the value of the respective varieties, the plants were regarded either from the point of view of producing disbudded blooms of good form and colour, or for their value as plants for the border, or for both purposes, and the awards of the Sub-Committee will show for what purpose the selected sorts should be grown. The following varieties each received three points on September 24:—

Horace Martin, bright yellow, good border plant, two-and-a-half feet; Harrie, bronzy orange, useful border plant, two feet; Florrie Wilkinson, buttercup-yellow sport from Polly, two feet; Hollicot Yellow (syn. Cranfordia), best early yellow, two-and-a-half feet; Hollicot Bronze (syn. Harvester), yellow, shaded bronze, two-and-a half feet; Cranford (syn. Chaldon), golden yellow, fine border plant, three-and-a-half feet; Candie, white, tinted carmine, very good, sport from Pluie d'Argent, one-and-a-quarter-foot; Mrs. Jack Pearson, bronze, continuous bloomer, border variety, three feet; Amber (Single), amber, very fine, border variety, two-and-a-half feet; Mrs. Phil Page, reddish-bronze, sport from Mrs. Jack Pearson, three feet; Golden Gleam (Single), golden amber, border variety, two-and-a-half feet; Harvest Glory, bronze sport from Hollicot Yellow, two-and-a-half feet; Crimson Circle, velvety crimson, one of the best garden varieties, two-and-a-half feet; Alex. McAlpine, terra-cotta; this variety is too much like Alex. Coyle, a good garden plant, two feet; Ronnie, rich yellow, of good form, border variety, two-and-a-quarter feet; Roi des Blancs, pure white, a spray variety, three and-a-half feet; Pink Dame, rose pink, good for border or disbudded, two-and-a-half feet; Jean, pale pink, good disbudded or in spray form, a border variety, three feet; Phoenix, bright chestnut, good border variety, three feet; Shirley Fawn, fawn, very fine flower, a border variety, three feet; and Tongo, bright orange, border variety, three feet.

Two points each were awarded to the following varieties on the same occasion:—

Chestnut, chestnut-red, very floriferous, border plant, three feet; Polly, orange, shaded amber, a good border plant, two-and-a-half feet; Crimson Polly, crimson-red sport from Polly, two-and-a-half feet; Firebrand (Single), fiery crimson, border variety, two and-a-half feet; Leslie, good early yellow for the border, two-and-a-half feet; Lizzie McNiel, primrose, a good border variety, two feet; Improved Masse, large, rosy-lilac, good form, two feet; Dick Barnes, Burgundy red, free border plant, two-and-a-half feet; Daffodil, rich yellow, promising for disbudding, three-and-a-half feet; Bronze Early Buttercup, rich bronze, good for disbudding, three-and-a-half feet; Afterglow, bronzy terra-cotta, very free and bushy, two feet; Mrs. R. J. Fielding, chestnut-red and gold sport from Goacher's Crimson, two feet; Low's White, still a good white sort, for sprays or border, three feet; Nina Blick, reddish-bronze, a good border plant, two-and-a-half feet; Lichfield Peach, peach colour, good for cut flowers, three feet; Anastasia (Pompon), rosy-purple, very compact and free, fifteen inches; September Yellow, canary-yellow sport from September White, four feet; Martin Reed, golden-yellow sport from Perle Chatillonaise, three-and-a-half feet; and White Chatillonaise, white sport from Perle Chatillonaise, three-and-a-half feet.

On the occasion of the second visit, October 8, three points were awarded to each of the undermentioned varieties:—

Perle Chatillonaise, creamy-white, tinted pink (as a family, this variety and its sports are good garden plants in a late season), three-and-a-half feet; Martin Reed, golden-yellow, sport from last-named, better on second visit), three-and-a-half feet; White Chatillonaise, white sport from Perle Chatillonaise, three-and-a-half feet; Bronze Chatillonaise (syn. J. Bannister). bronze sport from Perle Chatillonaise, three-and-a-half feet; Almirante, bright orange-bronze, best of its colour, rather late, three feet; Alcalde (syn. Red Almirante), bright crimson sport from Almirante, three feet; Hollicot Beauty (syn. September Glory and Shirley Conquest), bright amber bronze, good disbudded, three feet; Dick Barnes, Burgundy-red, better on second visit, two-and-a-half feet; Betty Spark, rose-pink, good for late sprays or border. two-and-a-half feet; Provence, rosy-pink, tipped gold, good border variety, two-and-a-half feet; Bronze Provence, pretty bronze sport from Provence, two-and-a-half feet; Pluie d'Argent, very fine white, grand border variety, one foot; Verona, bright terra-cotta, a good border variety, two feet; Sunstar (Single), golden-chestnut, a border plant, two feet; Gloria, pure yellow sport from Hollicot Beauty, a variety for disbudding, three feet; Candida (syns. Sanctity and Excelsior), best disbudded white, two feet; and Mrs. W. H. Webber, pink, a border variety.

On the same occasion the following varieties were each awarded two points:—

Framfield Primrose (syn. William Ritchie and Framfield Early Yellow), primrose, good disbudded, three feet; Framfield Early White, quite a fine white, disbudded, three feet; Mabel Roberts, deep pink, good disbudded, three feet; Goacher's Crimson, crimson, still a serviceable variety, two feet; Glow, crimson, tipped gold, good grower, should be disbudded, three feet; Royal Gold, golden-yellow, for sprays and border culture, rather late, three-and-a-half feet; Stanley Baldwin (Single), distinct cherry-crimson colour, border, two feet; September White, white, good border variety, three-and-a-half feet; Champ d'Or, rich yellow, good late garden variety, two feet; Cranford Red, chestnut-red, good bushy garden plant, two-and-a-half feet; Bonnie Lass, deep silvery pink, good garden variety, one-and-three-quarter feet; Alex. McAlpine (syn. Alex. Coyle, or very like it); Mrs. James Scalley, deep rose-pink, border variety, three feet; Madame C. Desgrange, a very old white, still a good garden variety, two-and-a quarter feet; Royal Salute, bright terra-cotta, border plant, rather late, two-and-a-half feet; Purple Robe, light purple, good border variety, two-and-a-half feet; Salmon Queen, salmon and bronze, good disbudded or for border, three feet; Silver Queen, silvery pink, good for disbudded blooms, three feet; Lillie, pearl-pink, a useful border plant, two feet; Minnie Carpenter, terra-cotta, good disbudded, or a border plant, two-and-a-half feet; Abercorn Beauty, deep bronze sport from Polly, two-and-a-half feet; Carrie, yellow, free-flowering, a good border sort, two feet; Golden Firebrand (Single), golden-yellow, border variety, two-and-a-half feet; Mignon, lilac-pink, erect habit, should be disbudded, two-and-a-half feet; J. Rotherham, salmon-buff, good garden variety, three feet; and Golden Security, golden-yellow, good disbudded, rather late, three-and-a-half feet.

Very many of the varieties sent in for trial proved to be useless for early-flowering out-of-doors. The Committee concluded that some sorts were "no good" and others "not wanted," and there were still others that were "promising, but too late." *C.*

MARKET FRUIT GARDEN.

The rainfall of October (3·85 inches) was nearly half-an-inch above the average, but much less than the deluge of the same month in 1928 (7·61 inches). This was fortunate, because there was still much picking of Apples to be done. The work continued throughout the month, but was almost finished at the close. Several gales were the worst feature of the weather, many Apples being brought to the ground and rendered less valuable than they would have been. The trees were revived by the rain, and remained remarkably green until quite the end of the month, even Plums still holding their leaves in many cases.

Storing Apples.

There has been little temptation to sell late varieties of cooking Apples, prices having been very low for such fruit. It seems likely that Bramley's Seedling will pay well for storing this year. Only in certain districts, of which mine is one, is there a heavy crop of this variety, and it is reported that imports of Apples will be considerably lighter than they were last winter. I am sorting out all the largest specimens of my Bramley's Seedling for sale at once and storing the rest. The big fruits do not keep so well as those of medium and small size, and they average 10s. per bushel now if packed in standard boxes. A few of the Apples have been of extraordinary size, packing only forty-five and fifty-six to the bushel box. The greater part of the crop, however, is on the small side. Since the fruits are by no means mature, they should keep well. My store room is quite a small affair, and is fully occupied at present by varieties which have to be held temporarily until they are fit for market. The problem of finding receptacles and accommodation for late Apples always occurs at the close of a season of heavy crops. Previously it has been solved by making heaps or clamps of some of the fruits, either under cover or in the open. I have determined never to adopt this plan again, because it results in a certain amount of marking of the fruits; and the labour of picking it up from the ground for packing is considerable and very trying. This time the difficulty has been overcome by clamping the fruits in the square bushel crates known under the National Mark scheme as cube boxes. The full boxes have been built up in a long, ridge-shaped pile, seven boxes wide in the bottom layer, then six, then five, and so on until one stands at the apex. Wire-netting was stretched over the pile and pegged down to the ground on each side of the clamp. Straw a foot thick was laid thatch-wise on this and held in place by another piece of wire-netting. My clamp now holds fully 2,000 bushels of Bramley's Seedling, or about thirty-six tons. Triangular spaces occur under the thatch at the extremity of each transverse row of boxes, forming flues from end to end of the clamp, through which I hope to be able to admit a draught when the temperature is low outside and the wind is in the right direction. When the interior has been cooled down in this way the ends of the clamp will be closed; and I do not expect to find much subsequent variation of temperature under such a thick thatch. It will be interesting to see how such a store answers. If the fruit keeps well until March it can hardly fail to increase greatly in value. Every rise of only one shilling per bushel means an extra £100 for the total contents. My experience is that, whereas large fruits increase in value by a few shillings per bushel, the small specimens, which are almost worthless in the autumn, double in price, although they are never wanted on the best markets.

Cox's Orange Pippin.

In a season when most of my Apples have been of high quality, Cox's Orange Pippin was disappointing, being far below the level of the past two years. The fruits would not attain the bright colour which is usual in my conditions, although allowed to hang until the lightest touch caused them to drop. This was due mainly to the dry summer, which did not favour colour, but partly to over-manuring, to which this variety appears to be very sensitive. Many of the fruits were of the large, pale, dull character which is associated with too much nitrogenous feeding. There was also a good deal of russetting caused by Bordeaux mixture made with hydrated lime, applied at the pink bud stage of the bloom. However, what the fruits lacked in colour and finish they made up in size, the proportion of "firsts" being greater than I am accustomed to. No other variety was packed for more than a week, and the financial result was distinctly pleasing. What a saleable variety this is. Even the roughest fruits can be disposed of at high prices if the right markets are used. It will be a great pity if its reputation is spoiled by the growing of some of the new varieties which resemble Cox's Orange Pippin in appearance, but which only distantly approach it in flavour. It is a pity that raisers should be so persistent in attempting to produce Apples with the flavour of this variety. So far as the production of new commercial varieties is concerned they would do better to use Worcester Pearmain as a parent variety, with a view to giving us Apples of high colour and good constitution.

Lime and Nitrogenous Fertilisers.

In a previous article, I mentioned the marked response made by nitrogen-starved trees in grass to manuring with lime-nitrogen fertilisers. It has been interesting to follow this response during the growing season. The leaves of both Plums and Apples remained dark green throughout the dry summer, in striking contrast to their poor appearance during the drought of the previous year; and most varieties have made plenty of growth. Plums held their foliage well into the autumn, and now appear to be smothered with fruit buds. Among Apples, some varieties have responded much more than others. Cox's Orange Pippin has made too much growth, and so have some blocks of Allington Pippin. Evidently caution must be used in the nitrogenous feeding of these varieties. Allington Pippin in particular yields the brightest clearest-skinned fruits from trees which are slightly under vigorous, that from more vigorous trees being too large, pale in colour, and with very much of the purple spotting to which this variety is liable. James Grieve is another Apple which must never be treated too generously. Worcester Pearmain, on the other hand, seems to require considerably more feeding, largely, no doubt, because it is not pruned beyond mere thinning out when growth becomes crowded. Lane's Prince Albert, as would be expected from such a weak grower, proves rather stubborn; and Newton Wonder appears to appreciate plenty of food. Evidently it will be necessary to give varieties of Apples individual treatment when applying nitrogenous fertilisers. Writing in general terms, the manuring done last winter increased the size of the Apples and reduced the colour. It also caused a very large proportion of the blooms to set, and has enabled the trees to form many prominent fruit buds in spite of the heavy crop. The breakdown of the old mat of mown grass by the lime-nitrogen fertilisers, particularly calcium cyanamide, has been rapid. A visiting grower recently remarked that the ground felt quite different to walk over. I am satisfied that the problem of manuring fruit trees under sod mulch treatment in my conditions has been solved. It remains only to regulate the amount of manure so as to keep the trees productive without spoiling the quality of the fruit—none too easy a matter with our varied climate. *Market Grower.*

FRUIT GARDEN.

PEARS, CURRANTS AND RASPBERRIES.

This has been a very good year for Pears, and from time to time we have had some very large specimens. The record here is held by Marguerite Marillat with 2¼ lbs. Fruits weighing 1¾ lb. are quite common, and this is the weight reached by some specimens of Charles Ernest. Doyenné du Comice has never reached 16 oz., but we have had many fruits which turned the scale above 15 oz.; in the case of this Pear with its melting flesh, large fruits are very good, but in the solid-fleshed Pears like Marguerite Marillat, the smaller fruits are preferable. Conference is a very good Pear of the buttery type. When perfectly ripe the flesh assumes an orange colour and can be peeled like a Peach.

Years ago, William Bateson gave me a plant of the pink Currant, variously known as the October or Dublin Currant. Apart from its curious colour, which resembles claret and water, this Currant hangs for a very long time, and we gathered some 2 lbs. from the bush on October 21.

In 1927, at Gravetye Manor, we all admired the immense crops of Raspberries from perpetual-fruiting varieties. Mr. Markham recommended Amélioré Congy, Large Orange and Supérlative Pérpetuelle; we obtained these varieties and planted them. They have done very well and began to bear early this autumn. I asked Mr. Markham to let me know how to treat the canes and he writes as follows:—

"Allow them to fruit so long as possible which is usually about the 20th to 25th of November and when the leaves have fallen, prune the tops off which have borne fruits and cut the long side-shoots close in. Then see that each cane is tied securely—I leave them in lines at one foot apart—and apply a dressing of manure, forking it lightly in during the winter. Next year these canes will commence to fruit at the same time as ordinary Raspberries and in the meantime young canes will develop from their base, which should be thinned (choosing the strongest) to one foot apart, and looped in as they advance.

"By the middle of August, the old canes will cease to fruit and should be removed, the earliest of the new canes being already well advanced with swelling fruits and in some instances ripe, hence there is scarcely a break."

Mr. Markham further tells me—the date being October 26—"I gathered 12 lbs. last Saturday in addition to 2 lbs. or 3 lbs. being gathered for dessert and cooking each day." *William Lawrence.*

PEAR GROWING IN ENGLAND.

Pear-growing in England is yet in its infancy In spite of the directions of our scientific institutions, cross-pollenation is still little practised. Then, too, the importance of the Quince stock is not appreciated. With the exception of a few varieties, only the Quince stock should be employed for Cordons or espaliers on ordinary soils, although the Pear stock may be used on soils of exceptional dryness, provided the trees are occasionally root-pruned.

If these conditions are observed and free-fruiting varieties are chosen, the popular saying that Pears are planted for heirs becomes a fallacy. The following varieties when grown on Quince and planted so that they may cross-pollenate each other, may be classed among regular bearers, ripening in the order given: Dr. Jules Guyot, Laxton's Superb (an excellent bearer and grower), Williams's Bon Chrêtien, Marie Louise d'Uccle (nearly always crops) Louise Bonne of Jersey, Fertility, Beurré Hardy, Comte de Lamy, Emile d'Heyst, Conference, Roosevelt, Winter Nelis, Beurré de Naghan, Beurré Diel, Santa Claus, Winter Nelis, Mrs. Seden and Easter Beurré.

It may be noted that some of these are not high quality Pears. Fertility, least of all, is useful because it nearly always fruits, and except during cold, wet seasons, is quite sweet if the fruits are exposed to the sun. It is one of the best of all Pears for cross-pollenation.

We certainly need more good early varieties, and there is room for the patient hybridiser willing to accept honour rather than cash as a reward. I have stated that we are only in our infancy with regard to Pear-growing in this country and can use our two best bearers, Fertility and Conference, as illustrations. Both these varieties have flowers differently constructed to most other sorts. While most Pears open their pollen masses or anthers at once and are so constructed, florally, that the stigmas are above the anthers, with Fertility and Conference the pollen masses or anthers are above the stigmas, and what is of greater importance still, these anthers, instead of opening nearly all at once, row follows row in sequence during many days.

Having regard to the very variable climate of the British Isles, it will be seen that varieties producing flowers of such construction as those of Fertility have what may be termed a better "sporting chance" to set their fruits. Instead of their anthers being in condition to fertilise the stigma of the flower for a few hours only, as is the case with some varieties, such sorts as Fertility and Conference have a period extending from a week to ten days (according to the weather), when the pollen may be in condition.

It is doubtful if the knowledge of fruit-growing in this country is generally more widespread and thorough than it was many years ago. It probably requires a greater skill to produce fruits of exceptional quality than anything else, because of the prolonged demands which it exacts. Gardeners able to produce fruits and vegetables from one end of the year to the other may certainly be classed as the most useful section of mankind; they are not sufficiently appreciated.

The one blemish at the fortnightly meetings of the Royal Horticultural Society is the absence of fruits for the Fellows to inspect. To see good Peaches one must go to Shrewsbury, they are not to be seen in London! In response to an apparently feeble demand, the greatest horticultural society of the world, which should be the greatest patron of the greatest and most important section of horticulture, has so far failed to produce a proper show of "Fruits in Season" at its fortnightly meetings. There are reasons for this which could, and should, be overcome. *Laurence J. Cook, Enfield.*

FRUIT REGISTER.

PEAR MRS. SEDEN.

THE subject of the illustration (Fig. 180), Pear Mrs. Seden, was raised by Messrs. James Veitch and Sons, Ltd., and named after their hybridiser's wife. It is an interesting variety for several reasons. At the first glance, its general appearance suggests an Apple rather than a Pear. Its claim to utility lies in its regular bearing habit when grown on Quince stock and cross-pollenated with another suitable variety, while its late-keeping qualities are excellent if the fruits are left on the tree until the end of October and not pulled prematurely, as is so often the case with late-keeping fruits. When ripe, the quality is good, but the fruits must be in condition to be classed as first-quality, and it is a good plan to remove the fruits from the cool temperature of the fruit room to a warmer place a few days before use. One of the parents of Mrs. Seden—Seckle—imparts its own distinct flavour to this variety, which is in season in January, its usefulness being enhanced by the length of the time (several weeks) when it may be eaten. Naturally, the period is lengthened by bringing fruits into a warmer position at intervals as required.

With me, Pear Mrs. Seden crops nearly every year. It is cross-pollenated by Fertility on one side and Durondeau on the other, all the trees being bushes, on Quince stock. *L. J. C.*

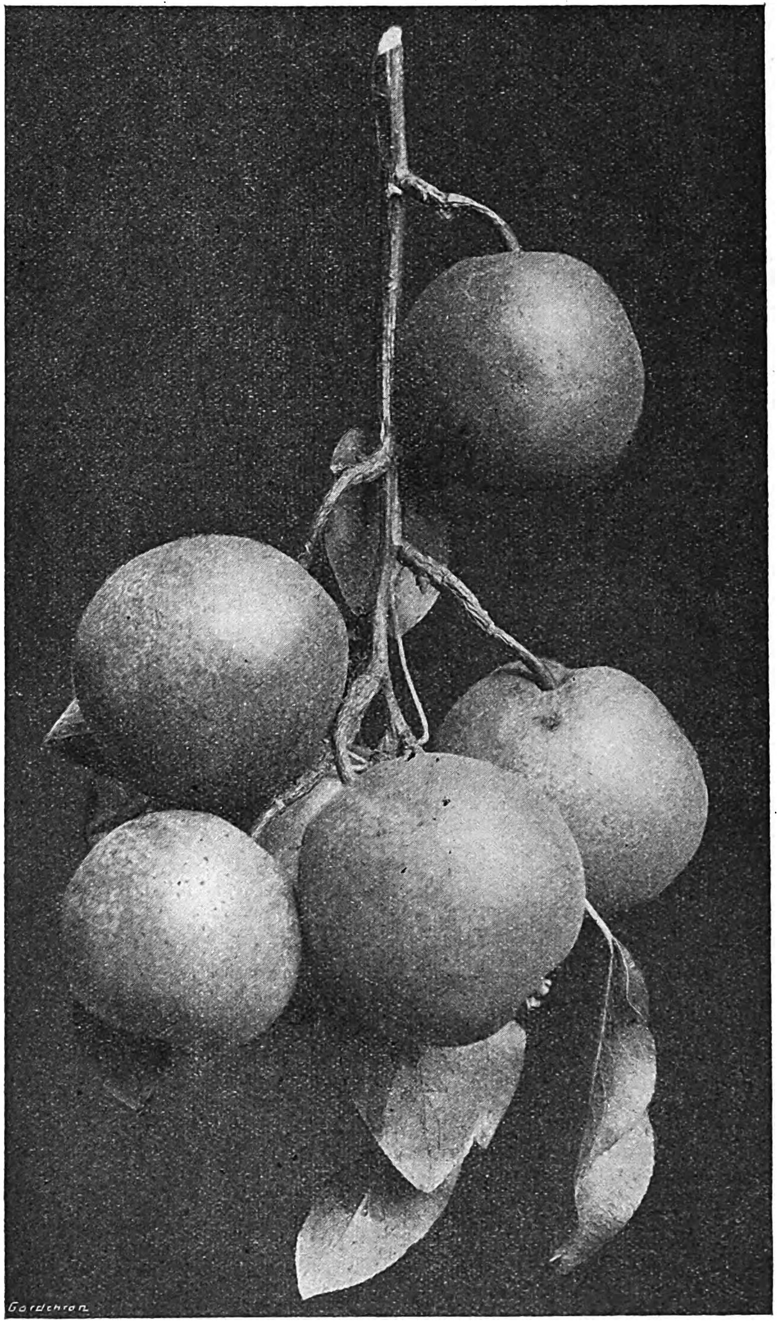

FIG. 180.—PEAR MRS. SEDEN.

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Lilium auratum.—Your correspondent's picture of, and notes on, his Lilium auratum, in *The Gardeners' Chronicle* of September 21 (p. 231), interested me. I enclose a "snap"—not deliberate photograph—of this Lilium growing not two miles from the centre of Manchester, in 1928 (Fig. 174). It had thirty-two flowers on the single stem, which showed no sign of fasciation. Both in 1926 and 1927 it flowered exactly in the same manner and carried the same number of flowers. It came safely through last winter without any artificial protection, but the bulb had split up, or the main bulb may have exhausted itself, leaving offsets only. That I have yet to find out. The bulb was in the first place, seven years ago, planted in the same manner as one would have potted it. More than a foot of soil was taken out, the bottom lifted and thoroughly broken up; next a good layer of broken crocks, then of moss, then a suitable compost, and the bulb. The position was shielded from the noon-day sun by Fern growths. *C. E. Sowerbutts, Crumpsall.*

Lonicera nitida.—As one grows old in gardens, one learns how unwise it is to praise unreservedly and to condemn without mercy. We have read both condemnation and praise of Lonicera nitida. Wisley was one of the centres from which Lonicera nitida was very widely distributed soon after its introduction about 1908 from China, where Mr. E. H. Wilson collected seeds. Our files contain many letters of grateful thanks from recipients and not a few photographs illustrating what has been done with the little plants so sent out. Hedges and screens and single plants many feet high and through are described, evergreen and pleasant to see for their shining leaves and close, neat habit, and valuable for their hardiness. *But*, alas, at Wisley it is easily the worst hedge plant we have ever planted and there are many kinds of hedges here. It would, after years of struggle, scarcely hide a hare. And single plants after a year or two of growth, gradually become miserable objects which ought probably to find their way to the fire, but that cuttings from them are going to give pleasure to others. Wisley is cold, of course, but it was not only the 35° of frost of last winter that killed it back; it is killed back nearly every winter, and yet it thrives in places nearly as cold as Wisley. It behaves badly not in one part of the garden only, but in places over a mile apart and in several different situations. Why? One would like to know. It is mostly in deep, lime-free, silty sand, always moist below, although often very dry and dusty on top, and it is both in the open exposed to all the winds that tear across some of our most exposed sites, and in sheltered spots where winds can scarcely reach it. In all alike it is unhappy. Perhaps those who write to praise will tell us what the secret is, and those who blame will tell us their environment, too, for it is not only in the lime-free soil of Wisley but in some places where the soil is too calcareous for Rhododendrons that it misbehaves. While one knows how well it grows in some places, one cannot utterly condemn, nor can one commend it for hedges while one knows how bad it is in others. *Fred J. Chittenden, Wisley.*

Dessert Plums for Market Growers.—I am much obliged to Mr. H. Dunkin for his suggestions as to choice Plums suitable for market growers (p. 371). I am afraid, however, that the varieties of Greengage mentioned are reliable only in certain districts, and that is why they are not universally grown for market. Years ago several Greengages were tried here in a mixed plantation of Plums, where there could hardly be any lack of pollenators. These included Oullins Golden and Denniston's Superb. All were grubbed out as being worthless, because they did not carry anything like a crop. I am not sure whether Jefferson was tested; but I certainly might give this a trial. *Market Grower.*
